Session: 162. PK/PD and Susceptibility Testing

Friday, October 4, 2019: 12:15 PM

Background. Options for the treatment of infections caused by resistant gram-negative bacteria are limited in children with kidney disease. Ceftriaxone (CFC) may be an attractive option but dosing recommendations are not available for children with renal dysfunction. We present a case of pharmacokinetics (PK) model-based individualization of CFD in an infant with kidney disease and mediastinitis. A 5-week-old infant with a hypoplastic left side of the heart developed mediastinitis following a Norwood and BT shunt. Blood and chest washout cultures grew S. epidermidis. Vancomycin therapy led to acute kidney injury (AKI) (eGFR ~15 mL/min) and therefore, CFD was initiated at 8 mg/kg every 12 hours. The model-based clinical service was consulted to assist with dosing.

Methods. Plasma levels were drawn on day 2 and 10 of CFD. CFD concentrations were determined by HPLC. The pharmacodynamic (PD) target used the MIC of the isolate, 1 µg/mL, and assumed drug diffusion into the mediastinum at 20% of plasma. The PD target was fT>MIC at 100%. Individual PK parameters were estimated using Bayesian estimation with the WinNonlin (Medware, the Netherlands).

Results. CFD dosing of 8 mg/kg every 12 hours resulted in concentrations well above the target. The trough level was 10 times higher than levels seen in clinical trials. Repeat levels were checked on day 10 due to improved renal function (eGFR 30 mL/min) and changes in volume status. Changes in both clearance and volume were noted. fT>MIC was maintained 100% during dosing intervals. We dose optimized CFD to achieve the target while minimizing potential toxicity with long-term use. A new dosing regimen, 3.4 mg/kg every 8 hours, was started on day 12 and continued for 6 weeks.

Conclusion. This is the first case report of CFD use in a child with AKI. Though initial dosing resulted in high concentrations, no adverse effects were noted. Successful treatment was completed with a final dosing regimen of 5.3 mg/kg every 8 hours, below the recommended range of mg/kg every 8 hours. Lower dosing was needed to decrease high drug exposure due to the decreased clearance. This case also demonstrated the feasibility of PK model-based precision dosing within 48 hours, and documented utility in the setting of changes in renal function. Further PK/PD studies are needed in children with renal dysfunction.

1544. Efficacy of Human-Simulated Ceferodol Exposure Against Gram-Negative Bacteria in an Iron-Overloaded Murine Thigh Infection Model

James M. Kidd, PharmD; Kamila Abdelraouf, PhD; David P. Nicolau, PharmD; Hartford Hospital, Hartford, Connecticut

Session: 162. PK/PD and Susceptibility Testing

Friday, October 4, 2019: 12:15 PM

Background. Ceferodol (CFDC) is a siderophore cephalosporin conjugate which exploits bacterial iron scavenging in reaction to the hypoferremic response of host immunity and achieves potent antibacterial activity. In patients with hereditary or iatrogenic hemochromatosis, the hypoferremic response may be altered by iron overload, which could hypothetically suppress host immunity and achieve potent antibacterial activity. We compared CFDC efficacy in Fe+ and NFe mice.

Methods. 17 of 20 individual isolates, no significant differences in efficacy between Fe+ and NFe mice were -1.98 (0.83) and -1.98 (0.72) log CFU/thigh, respectively. Mean (SD) efficacies of CFDC in Fe+ and NFe mice were -3.49 (0.73) and 3.42 (0.96) log CFU/thigh, respectively. For 17 of 20 individual isolates, no significant differences in efficacy between Fe+ and NFe mice were noted (P > 0.05); 2 of the 3 isolates with a difference had greater efficacy in Fe+ mice.

Conclusion. Human-simulated exposure of CFDC is equally efficacious in iron-overloaded and normal hosts against a variety of GNB susceptible to CFDC. The potential clinical use of CFDC to treat GNB infections in patients with iron overload is supported.

Woods, MD; Francesco Ciummo, PharmD, BCCCP; Ami Shah, PharmD, BCCCP; Joseph Sassine, MD; Christian Olivo Freites, MD; George Daroczi, PhD; Asherena Yasin, PharmD; Mount Sinai West Hospital, New York, New York; Mount Sinai East, New York, New York; Long Island University Pharmacy, Hackensack, New Jersey; Mount Sinai St Luke’s Hospital, New York, New York; Mount Sinai St Luke’s and Mount Sinai West Hospitals, New York, New York; Icahn School of Medicine at Mount Sinai St Luke’s and West Hospitals, New York, New York; 10 Optimus Dosing Strategies, Budapest, Budapest, Hungary; Mount Sinai St Luke’s Hospital, New York, New York

Session: 162. PK/PD and Susceptibility Testing

Friday, October 4, 2019: 12:15 PM

Background. Torsades de pointes is a life-threatening ventricular tachycardia associated with prolongation of the QT interval. Many diseases and medications have been implicated as potentially prolonging the QT interval, but little data exists regarding the means of quantifying this risk. The aim of this study was to describe the impact of commonly used antimicrobials on the QT interval in hospitalized patients.

Methods. Demographic, diseases, laboratory, medication administration history and ECG recording data were collected from the electronic records of adult patients admitted, from July 2018 to December 2018, to two urban hospitals. A model for the QT interval comprised of four sub-models: gender, heart rate, circadian rhythm, and the drug and disease effects. Fixed and random effects with between occasion variability were estimated for the parameters. A Bayesian approach using the NUTS in Stan was used via the brms package in the R software.

Results. Data from 1,353 patients were used with baseline characteristics shown in Table 1. Observed vs. predicted plots based on the training (Figure 1A) and validation data set (Figure 1B) showed a great fit. The parameters for QT, a, gender, and circadian effects were -1.519 (0.249), 162.39 (10.24), and 0.214 (0.15), respectively, that is > 5 ms longer vs. no treatment, the minimum cutoff that should evoke further risk assessment of QT interval prolongation.

Conclusion. The model developed correctly describes the impact baseline risk factors have on the QT interval. Point estimates of QT interval prolongation show that patients treated with fluconazole and levofloxacin may be at considerable risk; while those treated with azithromycin or ciprofloxacin are more likely to be at an insignificant risk for QT interval prolongation during hospital admission. Further workup to quantify the impact of concomitant treatment with these and other at-risk medications is underway.
Patient outcomes and prevention of resistance.

We have previously demonstrated that daptomycin (DAP) combinations with β-lactams offer enhanced bactericidal activity and prevent the emergence of resistance in Enterococcus faecium infections. Although the mechanisms of DAP resistance in enterococci are not fully comprehended, they are associated with alterations in cell envelope phospholipids assembly which leads to either repulsion of the drug from cell exterior or diversion from the cell septum. In this context, we sought to evaluate combinations of DAP with a panel of β-lactams including ampicillin (AMP), amoxicillin (AMX), ceftaroline (CPT), ceftriaxone (CRO) and ertapenem (ERT).

Methods. E. faecium R497 harboring liaSFR mutations (DAP MIC of 16 mg/L) was evaluated in a simulated endocardial vegetation (SEV) pharmacokinetic and pharmacodynamic model over 136 h at a starting inoculum of 10^6 CFU/g. DAP 10 mg/kg/day combinations with AMP, AMX (2 g continuous infusion), CPT 600 mg q 12 h, CRO 2g q 24 h or ERT 1 g q 24 h were evaluated. The emergence of DAP resistance was determined daily over the course of treatment.

Results. DAP alone was not bactericidal and high-level DAP resistance was observed (MIC increase from 16 to 64 µg/mL). Combination of DAP+AMP offered a significant reduction in log_10(CFU/g) amounts (Up to 7 log_10 CFU/g and to detection limits) in 24 h in with no emergence of DAP resistance. DAP 10+ AMX caused 6–6.5 log_10 CFU/g reduction and counts were maintained around the detection limit while demonstrating no increased resistance. Dose de-escalation with AMP indicated that even DAP 4 mg/kg/d with AMP (2g) combination, reached detection limit at 168 h with no further resistance. None of the CPT, CRO or ERT regimens in combination with DAP was effective against R497 and elevated DAP MICs (>64 µg/mL) was observed during the 14-day model.

Conclusion. Combination of DAP+AMP offered the most encouraging results against E. faecium R497, while DAP+AMX caused enhanced reduction. The reason for this discrepancy in various β-lactam activity may be related to diverse β-lactam targetings or affinity toward PBP proteins. Further dissection of our observations is warranted to understand the optimized DAP-β-lactam combination and consequently improve patient outcomes and prevention of resistance.
