Abstract

Pirillo and Varricchio, and independently, Halbeisen and Hungerbühler considered the following problem, open since 1994: Does there exist an infinite word \( w \) over a finite subset of \( \mathbb{Z} \) such that \( w \) contains no two consecutive blocks of the same length and sum? We consider some variations on this problem in the light of van der Waerden’s theorem on arithmetic progressions.

1 Introduction

Avoidability problems play a large role in combinatorics on words (see, e.g., [9]). By a square we mean a nonempty word of the form \( xx \), where \( x \) is a word; an example in English is murmur. A classical avoidability problem is the following: Does there exist an infinite word over a finite alphabet that contains no squares? It is easy to see that no such word exists if
the alphabet size is 2 or less, but if the alphabet size is 3, then such a word exists, as proven by Thue [13, 14] more than a century ago.

An abelian square is a nonempty word of the form \( xx' \) where \(|x| = |x'|\) and \( x' \) is a permutation of \( x \). An example in English is **reappear**. In 1961, Erdős [2] asked: Does there exist an infinite word over a finite alphabet containing no abelian squares? Again, it is not hard to see that this is impossible over an alphabet of size less than 4. Evdokimov [3] and Pleasants [12] gave solutions for alphabet size 25 and 5, respectively, but it was not until 1992 that Keränen [7] proved that an infinite word avoiding abelian squares does indeed exist over a 4-letter alphabet.

Pirillo and Varricchio [11], and independently, Halbeisen and Hungerbühl [5], suggested yet another variation. Let a sum-square be a factor of the form \( xx' \) with \(|x| = |x'|\) and \( \sum x = \sum x' \), where by \( \sum \) we mean the sum of the entries of \( x \). Is it possible to construct an infinite word over a finite subset of \( \mathbb{Z} \) that contains no sum-squares? This very interesting question has been open for 15 years. Halbeisen and Hungerbühl observed that the answer is “no” if we omit the condition \(|x| = |x'|\). Their tool was a famous one from combinatorics: namely, van der Waerden’s theorem on arithmetic progressions [15].

**Theorem 1.** (van der Waerden) Suppose \( \mathbb{N} \) is colored using a finite number of colors. Then there exist arbitrarily long monochromatic arithmetic progressions.

In this note we consider several variations on the problem of Pirillo-Varricchio and Halbeisen-Hungerbühl (the PVHH problem, for short). In Section 2, we show there is no infinite abelian squarefree word in which the difference between the frequencies of any two letters is bounded above by a constant. Section 3 deals with the problem of avoiding sum-squares, modulo \( k \). While it is known there is no infinite word with this property (for any \( k \)), we show that there is an infinite word over \( \{-1,0,1\} \) that is squarefree and avoids all sum-squares in which the sum of the entries is non-zero.

In Section 4, we provide upper and lower bounds on the length of any word over \( \mathbb{Z} \) that avoids sum-squares (and higher-power-equivalents) modulo \( k \). We conclude with some computational results in Section 5.

## 2 First Variation

We start with an infinite word \( w \) already known to avoid abelian squares (such as Keränen’s, or other words found by Evdokimov [3] or Pleasants [12]) over some finite alphabet \( \Sigma_k = \{0,1,\ldots,k-1\} \). We then choose an integer base \( b \geq 2 \) and replace each occurrence of \( i \) in \( w \) with \( b^i \), obtaining a new word \( x \). If there were no “carries” from one power of \( b \) to another, then \( x \) would avoid sum-squares. We can avoid problematic “carries” if and only
if, whenever \( xx' \) is a factor with \( |x| = |x'| \), then the number of occurrences of each letter in \( x \) and \( x' \) differs by less than \( b \). In other words, we could solve the PVHH problem if we could find an abelian squarefree word such that the difference in the number of occurrences between the most-frequently-occurring and least-frequently-occurring letters in any prefix is bounded. As we will see, though, this is impossible.

More generally, we consider the frequencies of letters in abelian power-free words. By an abelian \( r \)-power we mean a factor of the form \( x_1x_2 \cdots x_r \), where \( |x_1| = |x_2| = \cdots = |x_r| \) and each \( x_i \) is a permutation of \( x_1 \). For example, the English word \( \text{deeded} \) is an abelian cube.

We introduce some notation. For a finite word \( w \), we let \( |w| \) be the length of \( w \) and let \( |w|_a \) be the number of occurrences of the letter \( a \) in \( w \). Let \( \Sigma = \{a_1, a_2, \ldots, a_k\} \) be a finite ordered alphabet. Then for \( w \in \Sigma^* \), we let \( \psi(w) \) denote the vector \((|w|_{a_1}, |w|_{a_2}, \ldots, |w|_{a_k})\). The map \( \psi \) is sometimes called the Parikh map. For example, if \( \Sigma = \{v, 1, s, e\} \), then \( \psi(\text{sleeveless}) = (1, 2, 3, 4) \).

For a vector \( u \), we let \( u_i \) denote the \((i + 1)\)st entry, so that \( u = (u_0, u_1, \ldots, u_{k-1}) \). If \( u \) and \( v \) are two vectors with real entries, we define their \( L^\infty \) distance \( \mu(u, v) \) to be

\[
\max_{0 \leq i < k} |u_i - v_i|.
\]

If \( w = b_1b_2 \cdots \) is an infinite word, with each \( b_i \in \Sigma \), then by \( w[i] \) we mean the symbol \( b_i \) and by \( w[i..j] \) we mean the word \( b_ib_{i+1} \cdots b_j \). Note that if \( i = j + 1 \), then \( w[i..j] = \epsilon \), the empty word.

**Theorem 2.** Let \( w \) be an infinite word over the finite alphabet \( \{0, 1, \ldots, k-1\} \) for some \( k \geq 1 \). If there exist a vector \( v \in \mathbb{Q}^k \) and a positive integer \( M \) such that

\[
\mu(\psi(w[1..i]), iv) \leq M
\]

for all \( i \geq 0 \), then \( w \) contains an abelian \( \alpha \)-power for every integer \( \alpha \geq 2 \).

**Proof.** First, note that

\[
\sum_{0 \leq i < k} v_i = 1.
\]

For otherwise we have \( \sum_{0 \leq i < k} v_i = c \neq 1 \), and then \( \mu(\psi(w[1..i]), iv) \) is at least \( |c - 1| \frac{1}{k} \), and hence unbounded as \( i \to \infty \).

For \( i \geq 0 \), define \( X^{(i)} = \psi(w[1..i]) - iv \). Then

\[
X^{(i+j)} - X^{(i)} = (\psi(w[1..i+j]) - (i+j)v) - (\psi(w[1..i]) - iv)
= \psi(w[i+1..i+j]) - jv
\]

(3)
for integers $i, j \geq 0$. For $i \geq 0$, define $\Gamma(i)$ to be the vector with $\binom{k}{2}$ entries given by $X^{(i)}_l - X^{(i)}_m$ for $0 \leq l < m < k$.

From (1), we know that $\Gamma(i) \in [-M, M]^{\binom{k}{2}}$. Let $L$ be the least common multiple of the denominators of the (rational) entries of $v$. Then the entries of $L\Gamma(i)$ are integers, and lie in the interval $[-LM, LM]$. It follows that $\{\Gamma(i) : i \geq 0\}$ is a finite set of cardinality at most $(2LM + 1)^k$.

Consider the map that sends $i$ to $\Gamma(i)$ for all $i \geq 0$. Since this is a finite coloring of the positive integers, we know by van der Waerden’s theorem that there exist $n, d \geq 1$ such that $\Gamma(n) = \Gamma(n + d) = \ldots = \Gamma(n + \alpha d)$.

Now $\Gamma(n + id) = \Gamma(n + (i + 1)d)$ for $0 \leq i < \alpha$, so

$$X^{(n+id)}_l - X^{(n+id)}_m = X^{(n+(i+1)d)}_l - X^{(n+(i+1)d)}_m,$$

for $0 \leq l < m < k$ and hence

$$X^{(n+(i+1)d)}_l - X^{(n+id)}_l = X^{(n+(i+1)d)}_m - X^{(n+id)}_m.$$ \hspace{1cm} (4)

for $0 \leq l < m < k$. Actually, it is easy to see that Eq. (4) holds for all $l, m$ with $0 \leq l, m < k$.

Using Eq. (3), we can rewrite Eq. (4) as

$$(\psi(w[n+id+1..n+(i+1)d]) - dv)_l = (\psi(w[n+id+1..n+(i+1)d]) - dv)_m$$

for $0 \leq l, m < k$. It follows that

$$|w[n+id+1..n+(i+1)d]|_l - dv_l = |w[n+id+1..n+(i+1)d]|_m - dv_m$$

and hence

$$|w[n+id+1..n+(i+1)d]|_l - |w[n+id+1..n+(i+1)d]|_m = d(v_l - v_m)$$ \hspace{1cm} (5)

for $0 \leq l, m < k$.

Now let $z = w[n+id+1..n+(i+1)d]$. Then Eq. (5) can be rewritten as

$$|z|_l - |z|_m = d(v_l - v_m)$$ \hspace{1cm} (6)

for $0 \leq l, m < k$. Note that

$$|z|_0 + |z|_1 + \cdots + |z|_{k-1} = |z| = d.$$ \hspace{1cm} (7)

Fixing $l$ and summing Eq. (6) over all $m \neq l$, we get

$$(k-1)|z|_l - \sum_{m \neq l} |z|_m = d(k-1)v_l - d \sum_{m \neq l} v_m$$
and hence by (2) and (7) we get

\[(k - 1)|z|_l - (d - |z|_l) = d(k - 1)v_l - d(1 - v_l)\].

Simplifying, we have \(k|z|_l - d = dkv_l - d\), and so \(|z|_l = dv_l\).

We therefore have \(\psi(w[n + id + 1..n + (i + 1)d]) = dv_l\), for \(0 \leq i < \alpha\). Hence \(w[n + 1..n + \alpha d]\) is an abelian \(\alpha\)-power.

The following special case of Theorem 2 is of particular interest.

**Corollary 3.** Suppose \(w\) is an infinite word over a finite alphabet such that in any prefix of \(w\), the difference of the number of occurrences of the most frequent letter and that of the least frequent letter is bounded by a constant. Then \(w\) contains an abelian \(\alpha\)-power for every \(\alpha \geq 2\).

**Proof.** Apply Theorem 2 with \(v = (\frac{1}{k}, \frac{1}{k}, \ldots, \frac{1}{k})\).

### 3 Second Variation

Our second variation is based on the following trivial idea: We could avoid sum-squares if we could avoid them (mod \(k\)) for some integer \(k \geq 2\). That is, instead of trying to avoid factors with blocks that sum to the same value, we could try to avoid blocks that sum to the same value modulo \(k\). The following result shows this is impossible, even if we restrict our attention to blocks that sum to 0 (mod \(k\)). More general results are known (e.g., \([6, 9, \text{Chap. 4}]\)), but we give the proof for completeness.

**Theorem 4.** For all infinite words \(w\) over the alphabet \(\Sigma_k = \{0, 1, \ldots, k - 1\}\) and all integers \(r \geq 2\) we have that \(w\) contains a factor of the form \(x_1x_2 \cdots x_r\), where \(|x_1| = |x_2| = \cdots = |x_r|\) and \(\sum x_1 \equiv \sum x_2 \equiv \cdots \equiv \sum x_r \equiv 0 \pmod k\).

**Proof.** For \(i \geq 0\) define \(y[i] = \left(\sum_{1 \leq j \leq i} w[i]\right) \mod k\); note that \(y[0] = 0\). Then \(y\) is an infinite word over the finite alphabet \(\Sigma_k\), and hence by van der Waerden’s theorem there exist indices \(n, n + d, \ldots, n + rd\) such that

\[y[n] = y[n + d] = \cdots = y[n + rd]\].

Hence \(y[n + (i + 1)d] - y[n + id] = 0\) for \(0 \leq i < r\). But

\[y[n + (i + 1)d] - y[n + id] \equiv \sum w[n + id + 1..n + (i + 1)d] \pmod k\],

so \(\sum w[n + id + 1..n + (i + 1)d] \equiv 0 \pmod k\) for \(0 \leq i < r\).
Theorem 4 shows that for all $k$ we cannot avoid $xx'$ with $|x| = |x'|$ and $\sum x \equiv \sum x' \equiv 0 \pmod{k}$. This raises the natural question, can we avoid $xx'$ with $|x| = |x'|$ and $\sum x \equiv \sum x' \equiv a \pmod{k}$ for all $a \neq 0 \pmod{k}$? As phrased, the question is not so interesting, since the word $0^\omega = 000 \cdots$ satisfies the conditions. If we also impose the condition that the avoiding word be not ultimately periodic, or even squarefree, however, then it becomes more interesting. As we will see, we can even avoid both squares and factors $xx'$ with $\sum x \equiv \sum x' \equiv a \pmod{k}$ for all $a \neq 0 \pmod{k}$ (with no condition on the length of $x$ and $x'$).

**Theorem 5.** Let the morphism $\varphi$ be defined by

$$
\begin{align*}
0 & \rightarrow 0 1 0' -1 \\
1 & \rightarrow 0 1 -11 \\
0' & \rightarrow 0' -10 1 \\
-1 & \rightarrow 0' -1 1 -1
\end{align*}
$$

and let $\tau$ be the coding defined by

$$
\begin{align*}
0, 0' & \rightarrow 0 \\
1 & \rightarrow 1 \\
-1 & \rightarrow -1
\end{align*}
$$

Then the infinite word $w = \tau(\varphi^\omega(0))$ avoids both squares and factors of the form $xx'$ where $\sum x = \sum x' \neq 0$.

**Proof.** The fact that $\varphi^\omega(0)$ exists follows from $0 \rightarrow 0 1 0' -1$, so that $\tau(\varphi^\omega(0))$ is a well-defined infinite word.

To make things a bit easier notationally, we may write $\overline{1}$ for $-1$.

First, let us show that $w$ avoids squares. Assume, to get a contradiction, that there is such a square $xx'$ in $w$, with $x = x'$, and without loss of generality assume $|x|$ is as small as possible. Let $n = |x|$, and write $x = x[1..n], x' = x'[1..n]$.

We call 4 consecutive symbols of $w$ that are aligned, that is, of the form $w[4i + 1..4i + 4]$, a block. Note that a block $B$ can be uniquely expressed as $\tau(\varphi(a))$ for a single symbol $a$. We call $a$ the inverse image of $B$.

Case 1: $|xx'| \leq 25$. It is easy to verify by exhaustive search that all subwords of length 25 of $w$ are squarefree. (There are only 82 such subwords.)

Case 2: $|x| \geq 13$. Then there is a block that begins at either $x[5], x[6], x[7], \text{ or } x[8]$. Such a block $y$ has at least 4 symbols of $x$ to its left, and ends at an index at most 11. Thus there
are at least 2 symbols of $x$ to the right of $y$. We call such a block (with at least 4 symbols to the left, and at least 2 to the right) a centered block.

Case 2a: $|x| \equiv 1, 3 \pmod{4}$. Then $x$ contains a centered block $y$. Hence $x'$ contains an occurrence of $y$ (call it $y'$) starting at the same relative position. Since $|x| \equiv 1, 3 \pmod{4}$, $y'$ overlaps a block $z$ starting at 1 or 3 positions to its left. Since $y$ is centered, $z$ lies entirely within $x'$. But this is impossible, since $y$ is a block, and hence starts with 0, while the second and fourth symbol of every block $z'$ is $\pm 1$. See Figure 1.

Case 2b: $|x| \equiv 2 \pmod{4}$. By the same reasoning, $x$ contains a centered block $y$, so $x'$ contains an occurrence of $y$ (called $y'$) starting at the same relative position. Since $|x| \equiv 2 \pmod{4}$, $y'$ overlaps a block $z$ starting at 2 positions to its left, and $z$ lies entirely within $x'$. But by inspection, this can only occur if

(i) $y$ starts with 01 and $z$ ends with 01; or

(ii) $y$ starts with 01 and $z$ ends with 01.

In case (i), $y$ is either 01101 or 010101, and $z = 0101$. If $y = 01101$, then consider the block $z'$ that follows $z$ in $y'$. It must begin 11, a contradiction. Hence $y = 010101$.

Now the first two symbols of $z$ precede $y'$ in $x'$ and hence must also precede $y' = y$ in $x$. Thus the block $y''$ that precedes $y$ in $x$ must end in 01; it is entirely contained in $x$ because $y$ is centered. Hence $y'' = 0101$, and $y''y$ is a shorter square in $w$, a contradiction. See Figure 2.

![Figure 1: Case 2a](image1)

![Figure 2: Case 2b(i)](image2)
In case (ii), $y$ is either 011 or 0101, and $z = 0101$. If $y = 0111$, then consider the block $z'$ that follows $z$ in $y'$. It must begin 1, a contradiction. Hence $y = 0101$.

Now the first two symbols of $z$ precede $y'$ in $x'$ and hence must also precede $y'$ in $x$. Thus the block $y''$ that precedes $y$ in $x$ must end in 01; it is entirely contained in $x$ because $y$ is centered. Hence $y'' = 0101$. Hence $y''y$ is a shorter square in $w$, a contradiction.

Case 2c: $|x| \equiv 0 \pmod{4}$. Then we can write $x = r x_1 x_2 \cdots x_j l$, $x' = r' x'_1 x'_2 \cdots x'_{j'} l''$, where $lr = x_0$ (this defines $l$), $l' r' = x'_0$, $l'' r'' = x'_{j+1}$, and $x_1, \ldots, x_j, x'_0, \ldots, x'_{j+1}$ are all blocks. Furthermore, since $x = x'$ and $\tau \circ \varphi$ is injective, we have $r = r'$, $x_1 = x'_1, \ldots, x_j = x'_{j}$, and $l' = l''$. See Figure 3. There are several subcases, depending on the index $i$ in $w$ in which $x$ begins.

![Figure 3: Case 2c](image)

Subcase (i): $i \equiv 1, 2 \pmod{4}$. Then $|r| = |r'| = |r''| = 2$ or 3. Since any block is uniquely determined by a suffix of length 2, we must have $r = r'$ and so $x_0 = x'_0$. Hence $x_0 \cdots x_j x_0 \cdots x_j$ corresponds to a shorter square in $w$, by taking the inverse image of each block, a contradiction.

Subcase (ii): $i \equiv 3 \pmod{4}$. Then $|l| = |l'| = |l''| = 3$. Again, any block is uniquely determined by a prefix of length 3, so $l' = l''$. Thus $x'_0 = x'_{j+1}$ and $x_1 \cdots x_j x'_0 x'_1 \cdots x'_{j+1}$ is a square. But each of these terms is a block, so this corresponds to a shorter square in $w$, by taking the inverse image of each block, a contradiction.

Subcase (iii): $i \equiv 0 \pmod{4}$. In this case both $x$ and $x'$ can be factored into identical blocks, and hence correspond to a shorter square in $w$, by taking the inverse image of each block, a contradiction.

This completes the proof that $w$ is squarefree.

It remains to show that if $x x'$ are consecutive factors of $w$, then $\sum x$ cannot equal $\sum x'$ unless both are 0.

First, we prove a lemma.
Lemma 6. Let $\zeta$ be the morphism defined by

\[
\begin{align*}
0,0' & \to 010'-1 \\
1 & \to 01-110'-1 \\
-1 & \to 1-1.
\end{align*}
\]

Then

(a) $\varphi^n \circ \zeta = \zeta^{n+1}$ for all $n \geq 0$.

(b) $\varphi^n(0) = \zeta^n(0)$ for $n \geq 0$.

Proof. (a): The claim is trivial for $n = 0$. For $n = 1$, it becomes $\varphi \circ \zeta = \zeta^2$, a claim that can easily be verified by checking that $\varphi(\zeta(a)) = \zeta^2(a)$ for all $a \in \{-1, 0, 1, 0')\}$.

Now assume the result is true for some $n \geq 1$; we prove it for $n + 1$:

\[
\begin{align*}
\varphi^{n+1} \circ \zeta & = (\varphi \circ \varphi^n) \circ \zeta \\
& = \varphi \circ (\varphi^n \circ \zeta) \\
& = \varphi \circ \zeta^{n+1} \quad \text{(by induction)} \\
& = \varphi \circ (\zeta \circ \zeta^n) \\
& = (\varphi \circ \zeta) \circ \zeta^n \\
& = \zeta^2 \circ \zeta^n \\
& = \zeta^{n+2}.
\end{align*}
\]

(b): Again, the result is trivial for $n = 0, 1$. Assume it is true for some $n \geq 1$; we prove it for $n + 1$. Then

\[
\begin{align*}
\zeta^{n+1}(0) & = \varphi^n(\zeta(0)) \quad \text{(by part (a))} \\
& = \varphi^n(\varphi(0)) \\
& = \varphi^{n+1}(0).
\end{align*}
\]

Now let $\psi : \{0, 1, -1\}^* \to \{0, 1, -1\}^*$ be defined as follows:

\[
\begin{align*}
0 & \to 010-1 \\
1 & \to 01-110-1 \\
-1 & \to 1-1
\end{align*}
\]
Note that $\psi$ is the map obtained from $\zeta$ by equating 0 and 0', which is meaningful because $\zeta(0) = \zeta(0')$. Then from Lemma 6 we get

$$\tau(\varphi^n(0)) = \psi^n(0)$$

for all $n \geq 0$.

Now form the word $v$ from $w$ by taking the running sum. More precisely, define $v[i] = \sum_{0 \leq j \leq i} w[j]$. We first observe that $v$ takes its values over the alphabet $\{0, 1\}$: From Eq. (8) we see that $w = \psi^\omega(0)$. But the image of each letter under $\psi$ sums to 0, and furthermore, the running sums of the image of each letter are always either 0 or 1. From this the statement about the values of $v$ follows.

Let $xx'$ be a factor of $w$ beginning at position $i$, with $|x| = n$, $|x'| = n'$. Then $w[i..i+n-1]$ has the same sum $s$ as $w[i+n..i+n+n'-1]$ if and only if $v[i+n+n'] - v[i+n] = v[i+n] - v[i] = s$. In other words, $w[i..i+n-1]$ has the same sum $s$ as $w[i+n..i+n+n'-1]$ if and only if $v[i], v[i+n]$, and $v[i+n+n']$ form an arithmetic progression with common difference $s$. However, since $v$ takes its values in $\{0, 1\}$, this is only possible if $s = 0$.

**Corollary 7.** There exists a squarefree infinite word over $\{0, 1, \ldots, k-1\}$ avoiding all factors of the form $xx'$ with $\sum x = \sum x' = a$ for all $a \not\equiv 0 \pmod k$.

**Proof.** Take the word $w = \psi^\omega(0)$ constructed above, and map $-1$ to $k - 1$.  

## 4 Upper and Lower Bounds

We call a word of the form $x_1x_2\cdots x_r$ where $|x_1| = |x_2| = \cdots = |x_r|$ and $\sum x_1 \equiv \sum x_2 \equiv \cdots \equiv \sum x_r \pmod k$ a congruential $r$-power (modulo $k$). As we have seen, the lengths of congruential $r$-powers, modulo $k$, are bounded. We now consider estimating how long they can be, as a function of $r$ and $k$.

Our first result uses some elementary number theory to get an explicit lower bound for congruential 2-powers.

**Theorem 8.** If $p$ is a prime, there is a word of length at least $p^2 - p - 1$ avoiding congruential 2-powers (modulo $p$).

**Proof.** All arithmetic is done modulo $p$. Let $c$ be an element of order $(p - 1)/2$ in $(\mathbb{Z}/(p))^*$. If $p \equiv 5, 7 \pmod 8$, let $a$ be any quadratic residue of $p$. If $p \equiv 1, 3 \pmod 8$, let $a$ be any quadratic non-residue of $p$. Let $e(k) = c^k + ak^2$ for $1 \leq k \leq p^2 - p$, and define $f$ as the first difference of the sequence of $e$'s; that is, $f(k) = e(k+1) - e(k)$ for $1 \leq k \leq p^2 - p - 1$. Then we claim that the word $f = f(1)f(2)\cdots f(p^2 - p - 1)$ avoids congruential squares (mod $p$).
To see this, assume that there is a congruential square in \( f \). Then the sequence \( e \) would have three terms where the indices and values are both in arithmetic progression, say \( k, k+r, \) and \( k+2r \). Then \((c^{k+r} + a(k + r)^2) - (c^k + ak^2) = (c^{k+2r} + a(k+2r)^2) - (c^{k+r} + a(k + r)^2)\). Simplifying, we get
\[
 c^{k}(c^r - 1)^2 = -2ar^2. \tag{9}
\]
If \( c^r \not\equiv 1 \pmod{p} \), then
\[
 c^k / (-2a) \equiv (r / (c^r - 1))^2 \pmod{p}. \tag{10}
\]
Now the right-hand side of \( (10) \) is a square \( \pmod{p} \), so the left-hand side must also be a square. But \( c^k \) is a square, since \( c = g^2 \) for some generator \( g \). So \(-2a\) must be a square. But if \( p \equiv 1, 3 \pmod{p} \), then \(-2\) is a square \( \pmod{p} \), so \(-2a\) is not a square. If \( p \equiv 5, 7 \pmod{p} \), then \(-2\) is a nonsquare \( \pmod{p} \), so \(-2a\) is again not a square.

Hence it must be that \( c^r \equiv 1 \pmod{p} \). Since we chose \( c = g^2 \) for some generator \( g \), this means that \( r \) is a multiple of \((p - 1)/2\), say \( r = j(p - 1)/2 \). Then the left-hand side of \( (9) \) is 0 \( \pmod{p} \), while the right hand side is \(-aj^2(p - 1)/2 \). If this is 0 \( \pmod{p} \), we must have \( j \equiv 0 \pmod{p} \). So \( j \geq p \). Then \( 2r \geq p(p - 1) \). This gives the lower bound.

We now turn to some asymptotic results. For the remainder of this section, as is typical in the Ramsey theory literature \([8]\), we use the language of colorings: assigning the \( i \)th letter of a string \( x \) to be equal to \( j \) can be viewed as coloring the integer \( i \) with color \( j \).

We first investigate the growth rate of the minimum integer \( n \) such that every \( k \)-coloring of \([1, n] \) admits a congruential \( 2 \)-power modulo \( k \), as \( k \to \infty \).

We start with some definitions. Let \( \Omega(3, k) \) be the smallest integer \( n \) such that every set \( \{x_1, x_2, \ldots, x_n\} \) with \( x_i \in [(i-1)k + 1, ik] \) contains a 3-term arithmetic progression. Let \( \mathcal{L}(k) \) be the minimum integer \( n \) such that every \( k \)-coloring of \([1, n] \) that uses the colors 0, 1, \ldots, \( k-1 \) admits a congruential 2-power (modulo \( k \)). Finally, let \( w_1(3, k) \) be the minimum integer \( n \) such that every 2-coloring of \([1, n] \) admits either a 3-term arithmetic progression of the first color, or \( k \) consecutive integers all with the second color.

**Lemma 9.** For any \( k \in \mathbb{N} \), we have \( \mathcal{L}(k) \geq \Omega \left( 3, \left\lfloor \frac{k}{2} \right\rfloor \right) - 1 \).

**Proof.** Consider a maximally valid set of size \( n = \Omega \left( 3, \left\lfloor \frac{k}{2} \right\rfloor \right) - 1 \), i.e., a largest set that avoids 3-term arithmetic progressions. Let \( S = \{s_1 < s_2 < \cdots < s_n\} \) be this set. Construct the difference set \( D = \{d_1, d_2, \ldots, d_{n-1}\} = \{s_2 - s_1, s_3 - s_2, \ldots, s_n - s_{n-1}\} \) so that \( |D| = n - 1 \). Note that for any \( d \in D \) we have \( d \in [1, k-1] \) (so that 0 is not used in this construction). We claim that \( D \) has no congruential 2-power. Assume, for a contradiction, that it does. Let \( \sum_{i=x}^{y} d_i \equiv \sum_{y+1}^{2y-x+1} d_i \pmod{k} \). Then, by construction of \( D \), we have
\[
 \sum_{i=x}^{y} d_i = s_{y+1} - s_x \quad \text{and} \quad \sum_{y+1}^{2y-x+1} d_i = s_{2y-x+2} - s_{y+1}.
\]
Hence, 
\[ 2s_{y+1} \equiv s_{2y-x+2} + s_x \pmod{k}. \]  
(11)

Since \( x, y + 1, 2y - x + 2 \) are in arithmetic progression, the number of intervals between \( s_x \) and \( s_{y+1} \) is the same as the number of intervals between \( s_{y+1} \) and \( s_{2y-x+2} \). Hence,

\[
\sum_{i=x}^{y} d_i = s_{y+1} - s_x \in \left[ (y - x) \left\lceil \frac{k}{2} \right\rceil + 1, (y - x + 2) \left\lceil \frac{k}{2} \right\rceil - 1 \right]
\]

and

\[
\sum_{y+1}^{2y-x+1} d_i = s_{2y-x+2} - s_{y+1} \in \left[ (y - x) \left\lceil \frac{k}{2} \right\rceil + 1, (y - x + 2) \left\lceil \frac{k}{2} \right\rceil - 1 \right].
\]

Since the length of each of these intervals is the same and is at most \( k - 1 \), we see that (11) is satisfied as an equality. Hence, \( s_x, s_{y+1}, s_{2y-x+2} \) is a 3-term arithmetic progression in \( S \), a contradiction. Thus, \( L(k) > |X| = n - 1 = \Omega(3,k) - 2 \) and we are done. \( \square \)

Continuing, we investigate the growth rate of \( L(k) \) through \( \Omega(3,k) \). We have the following result.

**Lemma 10.** For all \( k \in \mathbb{N} \), \( w_1(3,k) \leq k\Omega(3,k) \).

*Proof.* Let \( m = \Omega(3,k) \) and let \( n = km \). Let \( \chi \) be any (red, blue)-coloring of \( [1,n] \). Assume there are no \( k \) consecutive blue integers. So, for each \( i, 1 \leq i \leq m \), the interval \( [(i-1)k+1, ik] \) contains a red element, say \( a_i \). Then, by the definition of \( \Omega(3,k) \), there is a 3-term arithmetic progression among the \( a_i \)'s. \( \square \)

Recently, Ron Graham \[1\] has shown the following.

**Theorem 11.** (Graham) There exists a constant \( c > 0 \) such that, for \( k \) sufficiently large, \( w_1(3,k) > k^{c\log k} \).

As a corollary, using Lemma 10, we have

**Corollary 12.** There exists a constant \( c > 0 \) such that, for \( k \) sufficiently large, \( \Omega(3,k) > k^{c\log k} \).

*Proof.* From Theorem 11 and Lemma 10 we have, for some \( d > 0 \),

\[
\Omega(3,k) \geq \frac{w_1(3,k)}{k} > k^{d\log k - 1} > k^{\frac{3}{2}\log k}.
\]

Taking \( c = \frac{d}{2} \) gives the result. \( \square \)
We now apply Corollary 12 to Lemma 9 to yield the following theorem, which states that \( \mathcal{L}(k) \) grows faster than any polynomial in \( k \).

**Theorem 13.** There exists a constant \( c > 0 \) such that, for \( k \) sufficiently large, \( \mathcal{L}(k) > k^{c \log k} \).

**Proof.** We have (suppressing constant terms)

\[
\mathcal{L}(k) \geq \Omega \left( 3, \left\lfloor \frac{k}{2} \right\rfloor \right) > \left( \frac{k}{2} \right)^{d \log \frac{k}{2}}
\]

for some \( d > 0 \), provided \( k \) is sufficiently large. Since \( \frac{k}{2} > \sqrt{k} \) for \( k > 4 \) this gives, for sufficiently large \( k \),

\[
\mathcal{L}(k) > k^{\frac{d \log k}{2}} > k^{\frac{d}{4} \log k}.
\]

Taking \( c = \frac{d}{4} \) yields the result. \( \square \)

We now turn from congruential 2-powers to the more general case of congruential \( t \)-powers. To this end, define \( \mathcal{L}(k, t) \) to be the minimum integer \( n \) such that every \( k \)-coloring of \([1, n]\) using the colors 0, 1, \ldots, \( k-1 \) admits a congruential \( t \)-power modulo \( k \).

Adapting the proof of Lemma 9 to this we immediately get

**Lemma 14.** For any \( k, t \in \mathbb{N} \), we have \( \mathcal{L}(k, t) \geq \Omega \left( t + 1, \left\lfloor \frac{k}{2} \right\rfloor \right) - 1 \).

Now, a result due to Nathanson \([10]\) gives us the following result.

**Theorem 15.** For any \( k, t \in \mathbb{Z}^+ \), we have

\[
\Omega \left( t + 1, \left\lfloor \frac{k}{2} \right\rfloor \right) \geq w \left( \left\lceil \frac{2t}{k} \right\rceil + 1; \left\lfloor \frac{k}{2} \right\rfloor \right).
\]

When \( k = 4 \), this gives us the following.

**Corollary 16.** For any \( t \in \mathbb{Z}^+ \) we have \( \mathcal{L}(4, t) \geq w \left( \left\lceil \frac{t}{2} \right\rceil + 1; 2 \right) - 1 \).

Hence, this says, roughly, that \( \mathcal{L}(4, 2\ell) \) serves as an upper bound for the classical van der Waerden number \( w(\ell, \ell) \).

A recent result of Bourgain \([11]\) implies the bound \( w(3; k) = o(k^{ck^{3/2}}) \) for some constant \( c > 0 \).

Hence, for sufficiently large \( k \), there exist constants \( c, d > 0 \) such that

\[
k^{c \log k} < \mathcal{L}(k) < k^{dk^{3/2}}
\]

so that we have a very rough idea of the growth rate.
5 Computational Results

As we have seen, the known upper bounds on van der Waerden numbers provide upper bounds for the length of the longest word avoiding congruential powers. We also did some explicit computations. We computed the length \( l(r, k) \) of the longest word over \( \Sigma_k \) avoiding congruential \( r \)-powers (modulo \( k \)), for some small values of \( k \) and \( r \), and the lexicographically least such longest word \( x_{r,k} \). The data are summarized below.

| \( r \) | \( k \) | \( l(r, k) \) | \( x_{r,k} \) |
|---|---|---|---|
| 2 | 2 | 3 | 010 |
| 2 | 3 | 7 | 0102010 |
| 2 | 4 | 16 | 0130102013101201 |
| 2 | 5 | 33 | 010214243213143040102142432131430 |
| 2 | 6 | 35 | 0102402124024140240124021240241402 |
| 2 | 7 | 47 | 01021614636032312426404301021614636032312426404 |
| 3 | 2 | 9 | 001101100 |
| 3 | 3 | 67 | 0010120112120012021202120212101200101210112012102102210112 |
| 4 | 2 | 88 | 00110010001001100110010011001100110011001100110011001100110011 |

It remains an interesting open problem to find better upper and lower bounds on the length of the longest word avoiding congruential powers.

6 Acknowledgments

We thank Thomas Stoll for a helpful observation. Theorem 8 was inspired by some related empirical calculations by Richard (Yang) Peng.
