Abstract

The Holst term represents an interesting addition to the Einstein–Cartan theory of gravity with torsion. When this term is present the contact interactions between vector and axial vector fermion currents gain an extra parity-violating component. We re-derive this interaction using a simple representation for the Holst term. The same representation serves as a useful basis for the calculation of one-loop divergences in the theory with external fermionic currents and cosmological constant. Furthermore, we explore the possibilities of the on-shell version of the renormalization group and construct equations for the running of dimensionless parameters related to currents and for the effective Barbero–Immirzi parameter.

Keywords: Barbero–Immirzi parameter, Einstein–Cartan theory, Renormalization group

1. Introduction

Einstein–Cartan theory attracts growing interest (see, e.g., [1–3] and references therein) because it represents the simplest possible extension of General Relativity (GR) related to the introduction of torsion field. The presence of torsion enables one to enrich the theory further by implementing the Holst term [4], which emerges naturally in the framework of loop quantum gravity [1, 5–7]. This parity-violating term should attract special interest since it can, in principle, yield some measurable observables for detecting quantum gravity. In order to better understand this point let us remember that in the Einstein–Cartan theory torsion becomes relevant only in the presence of fermion currents. After being integrated out, torsion provides contact interactions between such currents. Obviously, the main possibility for the

1 Also at Tomsk State Pedagogical University.
Holst term, in this respect, is related to the generation of parity-violating contact interaction between vector and axial vector fermion currents. The first purpose of the present communication is to present a very simple derivation of the Holst term in terms of irreducible components of the torsion tensor. We show that the new term is the simplest possible parity-violating scalar, and hence the Barbero–Immirzi parameter [8, 9] can be seen as an extra non-minimal parity-violating extension of the Einstein–Cartan action. Using this new form we recalculate the contact interaction between fermion currents depending on the Barbero–Immirzi parameter. Our results correspond well with the previous results of other authors [1, 6, 10, 11].

The main motivation for the Barbero–Immirzi parameter is related to Quantum Gravity (QG), so it is natural to see what can be the role of such a term in the loop corrections. Since both quantum GR and quantum Einstein–Cartan theory are not renormalizable, this issue cannot be addressed in the conventional framework of perturbative quantum field theory for the metric and torsion. The existing publications in this direction use very different approaches. The first of them is based on the functional renormalization group [12]. This powerful method is essentially non-perturbative, and in case of QG there is no perturbative limit, at least in the case of quantum GR. At the same time, there is a known difficulty related to the gauge-fixing dependence of the results of the functional renormalization group applied to gauge theories [13, 14] (see also many other references therein). In fact, the gauge-fixing dependence in this theory persists on-shell [14] and leads to the gauge dependent S-matrix and possibly all other relevant observables. One can expect that the same strong gauge dependence will take place also in the case of QG, and this creates certain difficulty for the physical interpretation of the results of this approach.

Another possibility is to rely on the renormalization group equations extracted from the quadratic one-loop divergences. This is technically possible, however the ambiguities which one usually meets in such a formulation are very strong and even go beyond the gauge fixing ambiguities. This aspect of QG has attracted significant interest recently, and the net result is that these ambiguities are generally uncontrollable (see, e.g., [15] and further references therein). For the Einstein–Cartan theory with the Barbero–Immirzi parameter this scheme was applied recently in [16], where the previous results for the one-loop divergences in the quantum GR with interacting fermion currents [17] have been used.

In the present work we use the third possibility for the quantum Einstein–Cartan theory. It is well-known that the pure quantum GR is renormalizable on-shell at the one-loop level [18]. This enables one to consider, for instance, the reduced on-shell version of the renormalization group for the Newton constant and cosmological term [19]. Let us note that this approach can be extended to become more informative when the calculations are performed on a special background such as de Sitter space [20], but our intention here is to follow a more simple method of [19]. A very nice feature of this approach is that the renormalization group equation for the dimensionless combination of the cosmological and Newton constants is gauge-fixing independent and, in this sense, is well defined. Of course, the on-shell renormalization group cannot be seen as a completely consistent method, but it is a useful starting point to deal with the QG theory.

The on-shell one loop renormalization group has been generalized for the case of the Einstein–Cartan theory in [21], in the theory with an external axial vector current. It was shown that the theory remains on-shell renormalizable at first loop in the presence of such current and quantum torsion. Here we intend to generalize these considerations in two ways, namely by including an additional vector current and also by incorporating the Holst term. We shall analyze to what extent the on-shell renormalizability can be preserved in such a theory and also consider the on-shell renormalization group to the extent it is possible.
The paper is organized as follows. In section 2, the classical consideration of the Einstein–Cartan theory with the Holst term and two (vector and axial vector) currents is presented. The derivation of one-loop divergences and analysis of the on-shell renormalizability of the theory is described in section 3. Section 4 contains the consideration of the on-shell renormalization group in the theory. Finally, in the last section we draw our conclusions and discuss possible prospects for future work.

2. Simple representation for the Holst term

In what follows we shall use the notations of [22], but will first reproduce the main formulas, for the convenience of the reader. The total action of gravity, including Einstein–Cartan and Holst terms, has the form

\[ S_{EC} + S_H = -\frac{1}{\kappa^2} \int \sqrt{-g} \, R - \frac{1}{2\gamma} \kappa^2 \int \sqrt{-g} \, \epsilon^{\alpha\beta\mu\nu} R_{\alpha\beta\mu\nu}, \]  

(1)

where \( G = \kappa^2/16\pi \) is Newton constant, also \( 16\pi/\kappa^2 = M_P^2 \). \( \gamma \) is the Barbero–Immirzi parameter. The scalar curvature is \( \tilde{R} = g^{\alpha\beta} g^{\gamma\delta} \tilde{R}_{\alpha\beta\gamma\delta} \) and \( \tilde{R}_{\alpha\beta\mu\nu} \) is the curvature tensor depending on the metric \( g_{\alpha\beta} \) and torsion \( T^\alpha_{\beta\gamma} \). This curvature is defined on the basis of asymmetric connection

\[ \Gamma^\alpha_{\beta\gamma} - \Gamma^\beta_{\gamma\alpha} - \Gamma^\gamma_{\alpha\beta} = 0. \]  

(2)

Assuming that covariant derivative with torsion satisfies the metricity condition \( \nabla_{\mu} g_{\alpha\beta} = 0 \), one can easily derive the relation between affine connection and Christoffel symbol

\[ \Gamma^\alpha_{\beta\gamma} = \Gamma^\gamma_{\beta\alpha} - \Gamma^\beta_{\gamma\alpha} + \Gamma^{\beta\gamma}_{\alpha} - \Gamma^{\gamma\beta}_{\alpha}, \]  

(3)

Here the contorsion tensor is

\[ K^\alpha_{\beta\gamma} = \frac{1}{2} (T^\alpha_{\beta\gamma} - T^\alpha_{\beta\gamma} + T^\alpha_{\gamma\beta}). \]  

(4)

The corresponding relations for curvature tensor and scalar with torsion have the form

\[ \tilde{R}^\lambda_{\alpha\beta\gamma} = R^\lambda_{\alpha\beta\gamma} + \nabla_{\alpha} K^\lambda_{\beta\gamma} - \nabla_{\beta} K^\lambda_{\alpha\gamma} + K^\lambda_{\alpha\beta} K^\gamma_{\gamma\lambda} - K^\lambda_{\beta\gamma} K^\gamma_{\alpha\lambda} - K^\lambda_{\alpha\gamma} K^\beta_{\gamma\lambda}, \]  

(5)

\[ \tilde{R} = R + 2 \nabla^\lambda K^\lambda_{\alpha\beta} - K^\lambda_{\alpha\beta} K^\gamma_{\gamma\lambda} + K^\lambda_{\alpha\lambda} K^\gamma_{\gamma\beta}, \]  

(6)

where the quantities without tildes are Riemannian, without torsion.

One can introduce three irreducible components of torsion as follows:

vector trace \( T^\alpha_{\beta\alpha} \)  

(7)

axial vector trace \( S^\alpha = \epsilon^{\alpha\beta\mu\nu} T_{\alpha\beta\mu\nu} \)  

(8)

tensor part \( q^\alpha_{\beta\gamma} \)  

(9)

when the last one satisfies the conditions \( q^\alpha_{\beta\alpha} = 0 \) and \( \epsilon^{\alpha\beta\mu\nu} q_{\alpha\beta\mu\nu} = 0 \).

2 One can use this reference and also many other sources, e.g., [23–25], for the introduction to different aspects of gravity with torsion.
The generic torsion can be easily expressed as
\[
\varepsilon = -\alpha \beta \mu - \beta \alpha \mu - \mu \alpha \beta + \alpha \beta \mu \nu \nu.
\] (10)
Now, replacing (10) into (4) and (6) we arrive at
\[
\tilde{R} = R - 2 V_\mu T^\mu - \frac{2}{3} T_\mu T^\mu + \frac{1}{2} q_{\alpha \beta} q^{\alpha \beta} + \frac{1}{24} S_\alpha S^\alpha.
\] (11)
Finally, repeating the same operation with (5) and then with the integrand of the Holst term, we arrive at the relation, which was already reported in [10] (see also [28] for more detailed consideration and more complete list of references on the history of the parity-violating terms in Einstein–Cartan theory,
\[
\varepsilon^{\alpha \beta \mu \nu} R_{\alpha \beta \mu \nu} = -\nabla_\mu S^\mu - \frac{2}{3} S^\mu T_\mu + \frac{1}{2} \varepsilon^{\alpha \beta \mu \nu} q^{\alpha \beta} q_{\mu \nu}
\]
\[
= -\nabla_\mu S^\mu - \frac{2}{3} S \cdot T + \frac{1}{2} \varepsilon \cdot q \cdot q.
\] (12)
In the last relation we have introduced condensed notations with dots for the contractions of two vectors and two tensors. The first of these notations will be used frequently in what follows.
One can see that the first part of the Holst term is rather simple in its representation (12). This term is nothing else but the simplest possible term violating parity. In fact, this term was not introduced as a non-minimal structure in the early works on quantum effects in gravity with torsion [21, 26] only because there was no interest in violating parity. For instance, the non-minimal structure \( \varphi^2 S^{\gamma} T_\gamma \) becomes relevant in the scalar sector if the parity-breaking nonminimal terms \( \varphi \gamma \gamma S_\gamma \gamma \) or \( \bar{\varphi} \gamma \gamma S_\gamma \gamma \) are introduced. In this case the Holst term can be easily obtained as part of the induced action (extended Einstein–Cartan) of gravity with torsion, e.g., it can result from some phase transition scheme, including spontaneous symmetry breaking.
In order to better understand the effect of the Holst term, let us include vector \( V^\mu \) and axial vector \( A_\mu \) fermion currents,
\[
V^\mu = \eta_1 \langle \bar{\psi} \gamma^\mu \psi \rangle \quad \text{and} \quad A_\mu = \eta_1 \langle \bar{\psi} \gamma^\mu \gamma \gamma \psi \rangle.
\] (13)
Let us note that the presence of non-minimal parameters \( \eta_1, 2 \) is the condition of consistency of the theory at the quantum level, especially if scalar fields and the Yukawa interactions of these fields with fermions are present [26] (see also [27] and [22] for extended discussions of this issue). For the sake of compactness of notations in the quantum part of the work, it is best to introduce rescaled currents \( J^\mu = -\kappa^2 A^\mu \) and \( W^\mu = -\kappa^2 V^\mu \), such that the total action becomes
\[
S_t = S_{EC} + S_H + \int d^4x \sqrt{-g} \left( V \cdot T + A \cdot S \right)
\]
\[
= -\frac{1}{\kappa^2} \int d^4x \sqrt{-g} \left\{ R + 2\Lambda - \frac{2}{3} T^2 + \frac{1}{2} q^2 + \frac{1}{24} S^2 - \frac{1}{3\gamma} S \cdot T - \frac{1}{2\gamma} V_\mu S^\mu + \frac{1}{2} \varepsilon \cdot q \cdot q + S \cdot J + T \cdot W \right\},
\] (14)
where we also used compact notations \( S^2 = S_\mu S^\mu \), \( T^2 = T_\mu T^\mu \) and \( q^2 = q_{\mu \nu} q^{\mu \nu} \).
3 We correct a misprint in the coefficient of \( T^2 \) term in [22].
As usual in the Einstein–Cartan theory, torsion is not dynamical field and can be integrated out. The dynamical equations for different components of torsion have the form

\[-\frac{4}{3} T^a - \frac{1}{3\gamma} S^a + W^a = 0 ,
\]
\[\frac{1}{12} S^a - \frac{1}{3\gamma} T^a + J^a = 0 ,
\]
\[q^{a\mu}=0 .\] (15)

According to the last equation we will not consider the component \(q^{a\mu}\) further. The first two equations can be easily solved in the form

\[T^a = \frac{3\gamma}{1 + \gamma^2} \left( J^a + \frac{\gamma}{4} W^a \right),
\]
\[S^a = \frac{3\gamma}{1 + \gamma^2} \left( W^a - 4\gamma J^a \right).\] (16)

One can observe that the presence of parity-violating parameter \(\gamma\) leads to the mixing between vector and axial vector currents. In principle, this mixing may have some strong phenomenological consequences, and it would be interesting to explore its consequences in particle physics. Such investigation could lead to the upper bounds of certain combinations of the Barbero–Immirzi parameter \(\gamma\) and the non-minimal parameters \(\eta_{1,2}\), introduced in (13).

However, in the present work our purpose is not phenomenology, instead we shall focus our attention on more formal aspects of the theory, related to QG.

The dynamical equation for the metric in the theory (14) leads to the on-shell relations

\[R_{\mu\nu} = D_{\mu\nu} - g_{\mu\nu} \left( A + \frac{1}{2} S \cdot J + \frac{1}{2} T \cdot W \right),\] (17)

where we introduced a useful notation

\[D_{\mu\nu} = \frac{2}{3} T_{\mu\nu} - \frac{1}{24} S_\mu S_\nu + \frac{1}{6\gamma} \left( S_\mu T_\nu + S_\nu T_\mu \right)\]
and also \(D = D^\mu_{\mu}\). (18)

Finally, replacing (16) into (17), after some algebra we arrive at the on-shell relations

\[R_{\mu\nu} \big|_{\text{on-shell}} = -4A g_{\mu\nu} + \frac{3\gamma}{1 + \gamma^2} \left( 2\gamma J^2 - \frac{\gamma}{8} W^2 - J \cdot W \right) g_{\mu\nu}
\]
\[+ \frac{3\gamma}{1 + \gamma^2} \left[ \frac{\gamma}{8} W_\mu W_\nu - 2\gamma J_\mu J_\nu + \frac{1}{2} \left( W_\mu J_\nu + W_\nu J_\mu \right) \right] \] (19)

and

\[R \bigg|_{\text{on-shell}} = -4A + \frac{3\gamma}{1 + \gamma^2} \left[ 6\gamma J^2 - \frac{3\gamma}{8} W^2 - 3W \cdot J \right].\] (20)

Finally, for the total action (14) on-shell we obtain

\[S_{\mu\nu} \bigg|_{\text{on-shell}} = -\frac{1}{\kappa^2} \int d^4x \sqrt{-g} \left\{ \frac{3\gamma}{1 + \gamma^2} \left( 4\gamma J^2 - 2J \cdot W - \frac{\gamma}{4} W^2 \right) - 2\Lambda \right\}.\] (21)

A simple observation concerning this action is as follows. In the limit \(\gamma \to \infty\) the mixed term with \((J \cdot W)\) goes to zero. This is of course a natural feature, because this parity-violating
term is only due to the presence of the Holst term. This detail is an illustration of the possible effects of the Holst term on the interaction between the two vector currents.

3. One-loop divergences off- and on-shell

The divergences must be calculated on the basis of the off-shell action (14). We shall treat $g_{\mu\nu}$, $S_\alpha$ and $T_\alpha$ as quantum fields while $W^\mu$ and $J^\mu$ will be taken as external sources. The Gaussian path integrals over $S_\alpha$ and $T_\alpha$ do not generate divergences, because the corresponding bilinear forms are $c$-number operators. This means that integrations over these variables is greatly simplified. Let us see this in more detail.

Consider the background field method for the action (14) and shift the field variable into background and quantum parts according to

$$g_{\mu\nu} \rightarrow g_{\mu\nu}' = g_{\mu\nu} + \kappa h_{\mu\nu}, \quad S_\mu \rightarrow S_\mu' = S_\mu + \kappa \sigma_\mu, \quad T_\mu \rightarrow T_\mu' = T_\mu + \kappa \eta_\mu.$$  

The one-loop effective action depends on the bilinear in respect to the quantum fields $h_{\mu\nu}$, $\sigma_\mu$, $\eta_\mu$ part of the action. Since we are going to work with on-shell quantities, the choice of the gauge fixing is irrelevant. For the sake of simplicity we consider De Donder gauge

$$S_{gf} = -\frac{1}{2} \int d^4x \sqrt{-g} \chi_\mu \kappa^{\mu}, \quad \text{where} \quad \chi_\mu = V_\lambda h^\lambda - \frac{\omega}{2} V_\mu h$$

and choose the gauge fixing parameters in a way that leads to the minimal bilinear form of the action, namely $\theta = \omega = 1$.

The expansion performs as usual (see, e.g., [27] for details) and after some algebra we arrive at

$$S^{(2)} + S_{gf} = -\int d^4x \sqrt{-g} \left( h^{\mu\nu} \left[ \frac{1}{4} \left( \delta_{\mu\nu,\alpha\beta} - \frac{1}{2} g_{\mu\nu} g_{\alpha\beta} \right) \square + \frac{1}{2} R_{\mu\nu,\alpha\beta} ight.ight.$$

$$+ \frac{1}{4} g_{\alpha\beta} R_{\mu\nu} - \frac{1}{4} \left( g_{\mu\alpha} R_{\nu\beta} + g_{\nu\beta} R_{\mu\alpha} \right)$$

$$- \frac{1}{4} \left( \delta_{\mu\nu, \alpha\beta} - \frac{1}{2} g_{\mu\nu} g_{\alpha\beta} \right) \left( R + 2\Lambda - \frac{2}{3} T^2 + \frac{1}{24} S^2 ight.$$

$$- \frac{1}{3} S \cdot T + S \cdot J + T \cdot W \left. \right)$$

$$- \frac{1}{96} \left( g_{\mu\nu} S_\alpha S_\beta + g_{\alpha\beta} S_\mu S_\nu \right) - \frac{2}{3} g_{\mu\alpha} T_\nu T_\alpha + \frac{1}{6} \left( g_{\mu\nu} T_\beta T_\rho + g_{\alpha\beta} T_\mu T_\nu \right)$$

$$- \frac{1}{6} \left( S_\mu T_\beta + S_\beta T_\mu \right) + \frac{1}{12} \left( g_{\mu\nu} S_\beta T_\nu + g_{\alpha\beta} S_\mu T_\mu \right)$$

$$+ \frac{1}{24} \left( g^{\mu\nu} \kappa_\alpha \sigma_\nu - \frac{1}{3} \delta^{\mu\nu} t_\nu \right. - \frac{1}{6} \left( \sigma_\mu g^{\nu\mu} t_\nu + \sigma_\nu g^{\mu\nu} t_\mu \right)$$

$$+ h^{\mu\nu} - \frac{1}{12} S_\mu \sigma_\nu + \frac{4}{3} T_\mu t_\nu + \frac{1}{3} \left( S_\mu t_\nu + T_\mu \sigma_\nu \right)$$

$$\left. + \frac{1}{24} g_{\alpha\beta} S_\mu \sigma_\nu \right] \left. + \frac{1}{2} g_{\alpha\beta} T_\mu t_\nu \right.$$}

$$+ \frac{2}{3} g_{\alpha\beta} T_\mu t_\nu - \frac{1}{96} g_{\alpha\beta} \left( T^\mu \sigma_\nu + S^\mu t_\nu \right)$$

$$+ \frac{1}{2} g_{\alpha\beta} \sigma_\mu J^\mu + \frac{1}{2} g_{\alpha\beta} T_\mu W^\mu \right] g_{\alpha\beta} \right) \right).$$

(24)
where $\delta_{\mu_\nu, a\beta} = (1/2)(g_{\mu\nu} s_{a\beta} + g_{\mu\beta} s_{a\nu})$. A relevant observation is that the path integral over $\sigma_\nu$ and $t_\mu$ has the form

$$I = \int dt_\mu \, d\sigma_\nu \exp \left\{ \int \left[ \frac{1}{2} (\sigma_\mu \, t_\mu) (K^{\mu\alpha}) \left( \sigma_\nu \right) + (\sigma_\mu \, t_\mu) \left( a^\mu \right) \right] \right\}, \quad (25)$$

where $K^{\mu\nu}$ is a $c$-matrix and $a^\mu$, $b^\mu$ form a column depending on the background fields. This non-derivative Gaussian integration gives

$$I = \exp \left\{ -\frac{1}{2} (a^\mu \, b^\mu) (K_{\mu\nu})^{-1} (a^\nu \, b^\nu) \right\}. \quad (26)$$

This is the same result that one could obtain by simply using the classical equations of motion for the two components of torsion $\sigma_\nu$ and $t_\mu$. Since our intention is to calculate the on-shell effective action, it means that we can simply ignore path integrals over $\sigma_\nu$ and $t_\mu$. That means there is no need to perform the shift of $S_\nu$ and $T_\mu$ in (22), instead one can directly use corresponding classical equations of motion in the result of the integration over quantum metric $h_{\mu\nu}$.

Finally, the relevant part of the bilinear expansion is

$$S^{(2)}_t + S_{gf} = -\int d^4 x \sqrt{-g} \ h^{\mu\nu} \left\{ \frac{1}{4} \left( \delta_{\mu_\nu, a\beta} - \frac{1}{2} g_{\mu\nu} s_{a\beta} \right) \Box + \frac{1}{2} R_{\mu\alpha\beta\gamma} + \frac{1}{2} g_{\mu\beta} R_{\mu\alpha} \\
- \frac{1}{4} (g_{\mu\nu} R_{a\beta} + g_{a\beta} R_{\mu\nu}) - \frac{1}{4} \left( \delta_{\mu_\nu, a\beta} - \frac{1}{2} g_{\mu\nu} s_{a\beta} \right) X + \frac{1}{4} Y_{\mu_\nu, a\beta} \right\} h^{a\beta}, \quad (27)$$

where

$$X = R + 2\Lambda - \frac{2}{3} T^2 + \frac{1}{24} S^2 - \frac{1}{3\gamma} S \cdot T + S \cdot J + T \cdot W \quad (28)$$

and

$$Y_{\mu_\nu, a\beta} = \frac{1}{6} g_{\mu\alpha} S_\alpha S_\beta - \frac{1}{24} \left( g_{\mu\alpha} S_\alpha S_\beta + g_{a\beta} S_{\mu} S_{\nu} \right) - \frac{8}{3} g_{\mu\alpha} T_\alpha T_\beta + \frac{2}{3} \left( g_{\mu\alpha} T_\alpha T_\beta + g_{a\beta} T_{\mu} T_{\nu} \right) \left( g_{\mu\nu} T_\alpha T_\beta + g_{a\beta} S_{\mu} S_{\nu} \right). \quad (29)$$

Furthermore, the equation (27) can be rewritten as

$$S^{(2)}_t + S_{gf} = -\int d^4 x \sqrt{-g} \ h^{\mu\nu} \left\{ \frac{1}{4} K_{\mu_\nu, a\beta} \Box + \frac{1}{4} M_{\mu_\nu, a\beta} \right\} h^{a\beta} \left( \delta_{\rho_\alpha, a\beta} \Box + \frac{1}{4} N_{\rho_\alpha, a\beta} \right) h^{\rho\alpha}, \quad (30)$$
where

\[ \hat{\Pi}_{\alpha\beta} = 2R_{\alpha\beta} + 2g_{\alpha\beta} R - \left( g_{\alpha\beta} R_{\alpha\beta} + g_{\alpha\beta} R_{\beta\alpha} \right) \]

\[ + \frac{1}{2} g_{\alpha\beta} g_{\rho\sigma} \nabla^\rho \nabla^\sigma X + \frac{1}{2} g_{\alpha\beta} Y_{\rho\sigma,\alpha\beta} \]

\[ + g_{\alpha\beta} \cdot g_{\rho\sigma, \alpha\beta} \cdot \Gamma_{\rho\sigma} = \Gamma_{\rho\sigma} + \hat{\Pi}_{\rho\sigma} \cdot \Box + \hat{\Pi}_{\rho\sigma} \cdot \nabla^\rho \nabla^\sigma X + \frac{1}{2} g_{\alpha\beta} Y_{\rho\sigma,\alpha\beta} \cdot g_{\rho\sigma}, \] (31)

and

\[ K^{-1}_{\mu\nu, \alpha\beta} = K_{\mu\nu, \alpha\beta} = \delta_{\mu\nu, \alpha\beta} - \frac{1}{2} g_{\mu\nu} g_{\alpha\beta}. \] (32)

The one-loop contribution is given by the standard expression

\[ \Gamma^{(1)} = \frac{1}{2} \text{Tr} \ln \left\{ \hat{K} \cdot (\Box + \hat{\Pi}) \right\} - i \text{Tr} \ln \hat{H}_{\text{ghost}}. \] (33)

The ghost part does not depend on torsion or external currents, thus the corresponding contribution will be identical to the standard one for Einstein gravity [18]. Let us, therefore, concentrate on the first term in (33). As far as \( \text{Tr} \ln \hat{K} = \text{Tr} \ln \hat{K}_{\mu\nu, \alpha\beta} \) does not contribute to the divergences, they depend only on the matrix \( \hat{\Pi}_{\rho\sigma} \) and also on the contribution of the Faddeev–Popov ghosts.

The practical calculation of divergences follows the standard scheme [18] and we will avoid boring the reader with the details. The result for the divergent part of the one-loop effective action can be conveniently expressed via the tensor quantity (18) and has the following final form:

\[ \Gamma^{(1)}_{\text{div}} = -\frac{1}{\epsilon} \int d^4x \sqrt{-g} \left\{ \frac{53}{45} E + \frac{7}{10} R_{\mu\nu}^2 + \frac{1}{60} R^2 + 8D_{\mu\nu}D^{\mu\nu} - 2D^2 + \frac{26}{3} R \left( \Lambda + \frac{1}{2} S \cdot J + \frac{1}{2} T \cdot W \right) + 20 \left( \Lambda + \frac{1}{2} S \cdot J + \frac{1}{2} T \cdot W \right)^2 \right\}, \] (34)

where \( E = R_{\mu\nu}^2 - 4R_{\mu\nu}^2 + R^2 \) is the Lagrangian density of the Gauss–Bonnet term (Euler density). Finally, \( \epsilon = (4\pi)^2(n - 4) \) is the parameter of dimensional regularization. Let us remark that (34) is relatively simple due to some unexpected cancellations, for example of the \( DR_{\mu\nu} R^{\mu\nu} \) and a few other possible structures.

In order to formulate the on-shell renormalization group, we need to use the classical equations of motion (16), (18), (19) and (20) in equation (43). After some algebra we arrive at the result

\[ \Gamma^{(1)}_{\text{div}} \bigg|_{\text{on-shell}} = -\frac{1}{\epsilon} \int d^4x \sqrt{-g} \left\{ \frac{53}{45} E - \frac{58}{5} \Lambda^2 + \frac{81 \gamma^4 J^4}{\left(1 + \gamma^2\right)^2} + \frac{81 \gamma^4 W^4}{\left(1 + \gamma^2\right)^2} + \frac{27 \gamma^2 \left(43 \gamma^2 + 58\right)}{40 \left(1 + \gamma^2\right)^2} W^2 \cdot J^2 + \frac{241 \gamma}{40 \left(1 + \gamma^2\right)^2} \left(16 \gamma J^2 - \gamma W^2 - 8W \cdot J\right) \Lambda \right. \]

\[ - \frac{27 \gamma^2 (W \cdot J)}{80 \left(1 + \gamma^2\right)^2} \left(56 + 116 \gamma^2\right)(W \cdot J) + 240 \gamma J^2 - 15 \gamma W^2 \right\}. \] (35)
An important difference between the expressions (34) and (35) is related to the gauge fixing dependence. The effective action (34) has a lot of ambiguity related to the choice of the parameters \( \theta, \omega \) in the action (23). In fact, a significant part of the terms can be modified or even eliminated by an appropriate choice of these parameters [29]. On the other hand, there is no such gauge dependence in the one-loop divergences for the on-shell effective action [19] (see also more detailed consideration in [30]), so the coefficients in the action (35) do not suffer from this ambiguity.

4. On-shell renormalization group

Our purpose is to construct the reduced on-shell version of the Minimal Subtraction renormalization group. We shall use dimensional regularization and hence it is necessary to formulate both classical on-shell action (21) and the on-shell counterterm in \( n \) space-time dimensions. The corresponding expressions can be written in terms of the new notations

\[ \tilde{\lambda} = \alpha_1 \lambda_1 + \alpha_2 \lambda_2 + \alpha_3 \lambda_3 + \alpha_4 \lambda_4, \] (36)

where

\[ \lambda_1 = \kappa^3 \Lambda, \quad \lambda_2 = \kappa^2 J^2, \quad \lambda_3 = \kappa^2 W^2, \quad \lambda_4 = \kappa^2 (W \cdot J) \] (37)
on one side and

\[ \tilde{\sigma} = \Omega_1 \lambda_1^2 + \Omega_2 \lambda_2^2 + \Omega_3 \lambda_3^2 + \Omega_4 \lambda_4^2 + \Omega_{12} \lambda_1 \lambda_2 + \Omega_{13} \lambda_1 \lambda_3 + \Omega_{14} \lambda_1 \lambda_4 + \Omega_{23} \lambda_2 \lambda_3 + \Omega_{24} \lambda_2 \lambda_4 + \Omega_{34} \lambda_3 \lambda_4 \] (38)
on another side.

The classical action and one-loop counterterms, both on-shell (classical) have the form

\[ S_{\text{on-shell}} = - \frac{1}{\kappa^4} \int d^nx \sqrt{-g} \mu^{n-4} \tilde{\lambda}, \] (39)

\[ \Delta S_{(1)}^{(\text{on-shell})} = \frac{1}{\epsilon} \cdot \frac{1}{\kappa^4} \int d^nx \sqrt{-g} \mu^{n-4} \tilde{\sigma}. \] (40)

The coefficients in the expressions (36) and (38) can be taken directly from equations (21) and (35)

\[ \alpha_1 = -2, \quad \alpha_2 = \frac{12\gamma^2}{(1 + \gamma^2)}, \quad \alpha_3 = -\frac{3\gamma^2}{4(1 + \gamma^2)}, \quad \alpha_4 = -\frac{6}{(1 + \gamma^2)} \] (41)
Let us note that consistent formulation of the renormalization group for both the cosmological constant and Newton constant (related to the inverse $\kappa$ of the re-scaled Planck mass) is definitely impossible since we are working in the framework of the on-shell renormalization group. The form of the classical action (39) and the counterterms (40) indicate that there is no possibility to study renormalization of $\kappa$ in this framework, so in what follows we will pursue only the aim of constructing the renormalization group equations for effective charges $\lambda_1, \lambda_2, \lambda_3$ and $\lambda_4$, defined in (37). One can also see this method as working in the Planck units, where all quantities become dimensionless.

The on-shell renormalized action has the form which follows from equations (39) and (40). Then the on-shell one-loop divergences can be removed by means of renormalization transformation

$$
\lambda_\mu = \mu^{-(n-4)} \left( \tilde{\lambda} - \frac{\tilde{\sigma}}{e} \right),
$$

As far as $\tilde{\lambda}_0$ does not depend on $\mu$, the last relation implies that

$$
(n-4) \left( \tilde{\lambda} - \frac{\tilde{\sigma}}{e} \right) + \left( \mu \frac{d\tilde{\lambda}}{d\mu} - \frac{\mu}{e} \frac{d\tilde{\sigma}}{d\mu} \right) = 0.
$$

Assuming that the divergent terms cancel, and using the homogeneity property of $\tilde{\sigma}$, we arrive at the general $\beta$-function for $\tilde{\lambda}$ in $n$ space-time dimensions,

$$
\beta_{\tilde{\lambda}} = -(n-4)\tilde{\lambda} - \frac{\tilde{\sigma}}{(4\pi)^2}.
$$

Since our intention is to explore the renormalization group in $n = 4$, we have to take the limit $n \to 4$, to arrive at the general renormalization group equation

$$
\frac{d\tilde{\lambda}}{dt} = \mu \frac{d\tilde{\lambda}}{d\mu} = \beta_\tilde{\lambda} = -\frac{\tilde{\sigma}}{(4\pi)^2},
$$

where we introduced a useful parameter $t = \ln (\mu/\mu_0)$.

The next part of the work will be to extract the equations for individual effective charges $\lambda_1, \lambda_2, \lambda_3$ and $\lambda_4$ from the single equation (46). This situation is definitely more complicated.
than the one in the usual renormalizable theories, and represents a necessary element of the
more tricky scheme of the on-shell renormalization group.

The case of the parameter $\lambda_1$ has been considered in the paper [19], where the on-shell
renormalization group was invented. Let us suppose that the renormalization group equation
for the cosmological constant $\lambda_1$ does not depend on the presence of external currents $J^\mu$ and
$W^\mu$. Setting $J^\mu = W^\mu = 0$ we get $\lambda_{2,3,4} = 0$ and then equation (46) transforms into

$$\alpha_1 \frac{d\lambda_1}{dt} = - \frac{1}{(4\pi)^2} \Omega_{11} \lambda_1^2.$$  

(47)

Taking $\alpha_1$ and $\Omega_{11}$ from (41) and (42), one can immediately obtain the corresponding equation
of [19],

$$\frac{d\lambda_1}{dt} = - \frac{29}{5(4\pi)^2} \lambda_1^2,$$  

(48)

indicating an asymptotic freedom for the dimensionless cosmological constant in the UV for a
positive cosmological constant and in the IR for a negative cosmological constant.

One can follow a similar approach for another effective charge, $\lambda_2$. In this case one has to
assume that when we set $\Lambda = 0$ and $W^\mu = 0$, the on-shell renormalization group equation for
the effective charge related only to $J^\mu$ does not change. Then the considerations similar to the
ones which led us to (47) and (48) provide us with the equation

$$\frac{d\lambda_2}{dt} = \beta_2 = - \frac{\Omega_{22}}{\alpha_2(4\pi)^2} \lambda_2^2 = - b_2^2 \lambda_2^2 = - \frac{27}{4(4\pi)^2} \left( \frac{\gamma^2}{1 + \gamma^2} \right) \lambda_2^2,$$  

(49)

indicating an asymptotic freedom for the dimensionless quantity $\lambda_2$ in the UV, in case the
vector $J^\mu$ is time-like, and in the IR in case the same vector is space-like.

In a similar way one can obtain the equation for the third parameter

$$\frac{d\lambda_3}{dt} = \beta_3 = - \frac{\Omega_{33}}{\alpha_3(4\pi)^2} \lambda_3^2 = b_3^2 \lambda_3^2 = \frac{27}{64(4\pi)^2} \left( \frac{\gamma^2}{1 + \gamma^2} \right) \lambda_3^2.$$  

(50)

In this case we observe the asymptotic freedom for the dimensionless quantity $\lambda_3$ in the UV if
vector $W^\mu$ is space-like, and in the IR in case this vector is time-like. For the sake of simplicity, we shall assume that the initial value of $\lambda_3(\mu_0) = \lambda_3^0$ is positive and that the initial value $\lambda_3(\mu_0) = \lambda_3^0$ is negative. In this case we have asymptotic freedom for both charges in
UV and will try to explore this limit in what follows. It is important to note that the signs of $\lambda_2$
or $\lambda_3$ are not limited by the arguments of stability or alike, in particular because they
correspond to the properties of external (non-dynamical) currents.

Now we can start solving a more complicated problem of formulating the on-shell
renormalization group equation for the effective charge $\lambda_4(t)$ and eventually for the effective
Barbero–Immirzi parameter $\gamma(t)$. By subtracting equations (49) and (50) with the factors $\alpha_2$
and $\alpha_3$, from equation (46) we obtain

$$\alpha_4 \frac{d\lambda_4}{dt} = \frac{1}{(4\pi)^2} \left( - \sigma + \Omega_{22} \lambda_2^2 + \Omega_{33} \lambda_3^2 \right)$$  

that directly brings us to

$$\frac{d\lambda_4}{dt} = - \frac{1}{\alpha_4} \left( \Omega_{44} \lambda_4^2 + \Omega_{23} \lambda_2 \lambda_3 + \Omega_{24} \lambda_2 \lambda_4 + \Omega_{34} \lambda_3 \lambda_4 \right).$$  

(51)
This is the renormalization group equation for the running parameter \( \lambda_4(t) \). The \( \beta \)-function here depends on \( \lambda_2(t) \) and \( \lambda_3(t) \), so the first impression is that one can solve equation (51) only after solving equations (49) and (50). However, the real situation is much more complicated. The parameter \( \lambda_4 \) is strongly related to \( \lambda_2 \) and \( \lambda_3 \), because all three constants are constructed from two fermion currents, \( J^u \) and \( W^u \), via equation (37). In fact, we have found the room for an independent equation (51) only because \( \lambda_4 \) depends not just on the magnitude of the currents \( J^u \) and \( W^u \), but also on the angle between them and on the Barbero–Immirzi parameter \( \gamma \). In what follows we assume that the mentioned angle does not run with the scale. This feature enables one to construct the renormalization group equation for \( \gamma \).

Let us derive the renormalization group equation for the Barbero–Immirzi parameter. To this end we return to the equations (49) and (50). Since \( \kappa \) is a universal constant (inverse Planck mass), one has to assume that the external currents themselves are running quantities, that means \( \mu = \alpha J \) and \( \mu = \alpha W \). By using (37), one can rewrite (49) and (50) as

\[
\frac{d\lambda_2}{dr} = \kappa^2 \frac{dJ^2}{dr} = 2\kappa^2 J^u \frac{dJ^u}{dr} = -\frac{\Omega_{22} \lambda_2^2}{\alpha^2(4\pi)^2} = \beta_2 ,
\]

\[
\frac{d\lambda_3}{dr} = \kappa^2 \frac{dW^2}{dr} = 2\kappa^2 W^u \frac{dW^u}{dr} = -\frac{\Omega_{33} \lambda_3^2}{\alpha^2(4\pi)^2} = \beta_3 .
\]

Let us make a natural assumption that

\[
\frac{dJ_u}{dr} = \Theta_2 J_u .
\]

Then it is easy to show that \( \Theta_2 = -\frac{\Omega_{22} \kappa^2 J^2}{2\alpha^2(4\pi)^2} \).

In the same way, we find

\[
\frac{dW_u}{dr} = \Theta_3 W_u , \quad \text{where} \quad \Theta_3 = -\frac{\Omega_{33} \kappa^2 W^2}{2\alpha^2(4\pi)^2} .
\]

Then we have two relations,

\[
\frac{dJ_u}{dr} = -\frac{\Omega_{22} \kappa^2 J^2}{2\alpha^2(4\pi)^2} J_u \quad \text{and} \quad \frac{dW_u}{dr} = -\frac{\Omega_{33} \kappa^2 W^2}{2\alpha^2(4\pi)^2} W_u .
\]

As far as \( \lambda_4 = \gamma \kappa^2 (W \cdot J) \), the renormalization group equation for \( \lambda_4 \) is a consequence of equations (56) and the running of \( \gamma \), which we also want to find. In this way one can obtain

\[
\frac{d\lambda_4}{dr} = \kappa^2 \left( \frac{d\gamma}{dr} W \cdot J + \gamma J^u \frac{dW^u}{dr} + \gamma W^u \frac{dJ_u}{dr} \right) .
\]

Replacing (51) into (57) and using equations (56), we arrive at

\[
(4\pi)^2 \gamma \frac{d\gamma}{dr} = -\frac{\Omega_{44} \lambda_4}{\alpha^4} + \lambda_2 \left( \frac{\Omega_{22}}{2\alpha^2} - \frac{\Omega_{24}}{\alpha^4} \right) + \lambda_3 \left( \frac{\Omega_{33}}{2\alpha^3} - \frac{\Omega_{34}}{\alpha^4} \right) - \frac{\lambda_2 \lambda_3}{\alpha_4^2 \lambda_4} \Omega_{23} .
\]

The last equation describes the renormalization group running of the Barbero–Immirzi parameter within the on-shell renormalization group scheme. In this consideration we assumed that the angle between the four-dimensional currents \( J^u \) and \( W^u \) does not run with
the renormalization group scale. This is a small price to pay for the possibility of considering the renormalization group in a non-renormalizable theory such as Einstein–Cartan gravity with the Holst term.

The problem of exploring the asymptotic behavior of the effective charges $\lambda_{2,3,4}(t)$ and $\gamma(t)$ on the basis of equations (49), (50), (51) and (58) turns out to be very complicated, and unfortunately we were unable to solve it in a completely satisfactory way. Let us present part of our consideration, which can be useful to show the origin of the difficulties.

The simplest assumption is that all four parameters $\lambda_{2,3,4}(t)$ and $\gamma(t)$ have moderate running and therefore one can work in the leading-log approximation. Then the equations (49) and (50) can be easily solved for a constant $\gamma$ and give

$$\lambda_2(t) = \frac{\lambda_{20}}{1 + b_2^2 \lambda_{20} t}, \quad \lambda_3(t) = \frac{\lambda_{30}}{1 - b_3^2 \lambda_{30} t}.$$  \hspace{1cm} (59)

In this case equation (51) can be easily cast into the form

$$\frac{d\lambda_4}{dt} = A(t)\lambda_4^2 + B(t)\lambda_4 + C(t).$$  \hspace{1cm} (60)

Mathematically, (60) is a Riccati equation, which can be solved if we first get some particular solution. In order to achieve this, we can make some simplifications. Consider an asymptotic regime, assuming $(b_2/\lambda_{20}) t \gg 1$ and $(b_3/\lambda_{30}) t \gg 1$, such that, approximately,

$$\lambda_{2,3}(t) \approx \frac{l_{2,3}}{t}, \quad \text{where} \quad l_2 = \frac{4(4\pi)^2 (1 + \gamma^2)}{27 \gamma^2} \quad \text{and} \quad l_3 = 16l_2.$$  \hspace{1cm} (61)

In this way equation (60) becomes simpler, i.e.,

$$\frac{d\lambda_4}{dt} = A_0 \lambda_4^2 + \frac{B_0}{t} \lambda_4 + \frac{C_0}{t^2},$$  \hspace{1cm} (62)

where

$$A_0 = -\frac{\Omega_{44}}{\alpha_4(4\pi)^2}, \quad B_0 = -\frac{2\Omega_{24} l_2 + \Omega_{44} l_3}{\alpha_4(4\pi)^2}, \quad C_0 = -\frac{\Omega_{23} l_2 l_3}{\alpha_4(4\pi)^2}.$$  \hspace{1cm} (63)

It is quite natural to look for a particular solution of equation (62) in the form

$$\lambda_4(t) = \frac{l_4}{t}, \quad \text{where} \quad l_4 = -\frac{B_0 + 1}{2A_0} \pm \frac{1}{2A_0} \sqrt{(B_0 + 1)^2 - 4C_0A_0}.$$  \hspace{1cm} (64)

In case of a real r.h.s. of the last expression, one can easily show that an arbitrary particular solution is asymptotically approaching (64). Unfortunately, a direct calculus shows that the root in equation (64) has only solutions with a non-zero imaginary part. This feature leaves very few chances to find a fixed point for the system of equations (49), (50), (51) and (58). According to (37), the parameter $\lambda_4$ can be complex only due to the complex parameter $\gamma$. This means that the ratio between real and imaginary parts of $\lambda_4$ and $\gamma$ should be identically equal. However, direct calculations show that this situation contradicts the equations (51) and (58). This means that the system of renormalization group equations for the effective parameters $\lambda_{2,3,4}(t)$ and $\gamma(t)$ has no fixed points.

The absence of the Holst term means the limit $\gamma \to \infty$ for the Barbero–Immirzi parameter. An inspection of the equations (49), (50) and (51) with $\Omega_{22}$ and $\Omega_{33}$ defined in (42) shows that in this limit there are usual UV fixed points, which can correspond to the asymptotic freedom in the parameters $\lambda_2(t)$, $\lambda_3(t)$ under the right choice of initial conditions. Therefore, the role of the Holst term in the renormalization group is very strong. Our
results show that the presence of finite $\gamma$ breaks down the simple form of the renormalization group flows and leads to much more complicated scale behavior which looks irregular, at least at the present stage of investigating the problem.

In this situation a natural question to ask is whether the limit $\gamma \to \infty$ for the Barbero–Immirzi parameter is smooth. It is easy to see that in this limit we also have $\lambda_4 \to \infty$. Therefore the smooth limit concerns the ratio between the two effective parameters, $p = \lambda_4/\gamma$. The equation for this ratio can be easily obtained from equations (37), (54) and (55). After a very small calculus we arrive at the equation

$$\frac{dp}{dt} = -\frac{p}{2(4\pi)^2} \left[ \frac{\Omega_{22}}{\alpha_2} \lambda_2(t) + \frac{\Omega_{33}}{\alpha_3} \lambda_3(t) \right], \quad p(0) = p_0. \tag{65}$$

Using the asymptotic estimates for $\gamma \to \infty$,

$$\Omega_{22} \propto 81, \quad \Omega_{33} \propto \frac{81}{256}, \quad \alpha_2 \propto 12, \quad \alpha_3 \propto -\frac{3}{4}, \tag{66}$$

we arrive at the solution of (65),

$$\frac{p(t)}{p_0} \propto \left( 1 + b_1^2 \lambda_{20} t \right)^{1/2} \left( 1 - b_0^2 \lambda_{30} t \right)^{-1/2}. \tag{67}$$

The last formula shows that we can switch off the Barbero–Immirzi parameter smoothly and the ratio $p(t) \to 0$ asymptotically at $t \to \infty$ in the same way as the effective charges $\lambda_2(t)$ and $\lambda_3(t)$. This shows that our hypothesis of a non-running angle between two currents is correct in the regime of a very small Holst term, at least. However, this confirmation concerns only this special limit.

Of course, the most interesting part is the running for a finite Barbero–Immirzi parameter, but in this case we could not achieve a reliable analytic estimate of the results. In this situation one can rely only on the numerical solution for the system of equations (49), (50), (51) and (58). The corresponding analysis has been done; however, the output shows very strong dependence on the choice of initial conditions and after all, there is no convincing qualitative interpretation of the results. For this reason, we decided not to bother the reader with the technical details here. One could imagine that the situation may become different in a more complete case when we also take the running of $\lambda_1$ into account. The technically more cumbersome analysis of this case has been performed and we have seen that there are not many changes. Qualitatively, the situation remains the same: that is, there are no nontrivial fixed points in the presence of a finite Barbero–Immirzi parameter.

5. Conclusions

We have considered the Einstein–Cartan theory with an additional Holst term, which plays an important role in loop quantum gravity [1, 6]. In classical theory this term is well known to identically vanish for zero torsion, and manifest itself only in the presence of fermion currents. Following [10], we used the irreducible components of torsion to write the Holst term in a simple form, where its parity-violating nature becomes clear.

In the main part of the paper we performed one-loop calculations in the Einstein–Cartan theory with the Holst term, cosmological constant and two external fermion currents, namely vector and axial vector. As one should expect, the divergences do not repeat the form of the classical action. On the other hand, the divergences have strong gauge-fixing dependence. In pure quantum GR one can choose the gauge-fixing in such a way that the one-loop $S$-matrix
becomes finite [29], however this is not the case if the matter is present, including fermions. Indeed, one does not need to calculate explicitly gauge-fixing dependence; it is sufficient to remember that, at the one-loop level, this dependence disappears on the classical mass-shell in a general gauge theory [31] (see also [14] for a recent review of the subject).

The real problem is how to extract the potentially relevant physical information from the gauge-dependent effective action. One of the simplest possibilities has been suggested by Fradkin and Tseytlin in [19], where the truncated on-shell version of renormalization group equations has been introduced. Within this scheme one can arrive at the gauge-invariant form of running for the dimensionless combination of the cosmological and Newton constants. The on-shell renormalization group has been also used in the Einstein–Cartan theory with axial vector current [21], but the situation becomes much more complicated and interesting in the presence of the Holst term.

It is clear that the on-shell renormalization group equations have a much more restricted theoretical background than the conventional renormalization group in renormalizable theories. However, even in the non-renormalizable theory such as Einstein–Cartan with the Holst term we were able to establish the renormalization group equations for all dimensionless effective charges, including cosmological constant, squares of both fermionic currents, the mixing of the two and finally, for the Barbero–Immirzi parameter $\gamma$. Unfortunately, the equations which we have obtained are very complicated and do not enable us to apply standard treatments. In particular, we were unable to find non-trivial UV fixed points in the theory or establish, by means of numerical methods, some reliable form of the renormalization group trajectories for the dimensionless effective charges.

Finally, let us present a short discussion of prospects that might extend our results. The set of equations which we have obtained here can be seen as a low-energy approximation for the renormalization group in the theory with full UV completion, which is supposed to be renormalizable. In the present case such a complete theory should include higher derivatives in the metric sector [32] and kinetic terms for torsion (see the discussion in [22, 27]). Only quantum calculations in such a full theory coupled to fermions [27, 33, 34] can provide a completely reliable form of the renormalization group equations in the theory with Barbero–Immirzi parameter. In practice, the derivation of such equations is possible but promises to be very involved, so we leave it for possible future work. At the same time, certain technical tools which we developed here will certainly be necessary for such a calculation.

Acknowledgments

The authors are grateful to Guilherme de Berredo-Peixoto and Cleber Abrahão de Souza for useful discussions about the Holst term. We are especially grateful to Prof. Friedrich Hehl, who explained to us a mistake in the equation (12) in the first version of the manuscript and also provided us with some relevant references. The work of the authors has been partially supported by CAPES, CNPq, FAPEMIG and ICTP (IS).
