1. Details of a typical synthesis of shape pure, nearly monodisperse ~8.5 nm CsPbBr$_3$ nanocubes using didodecylamine (DDDAm)

1$^{\text{st}}$ step, Degassing: 76 mg of lead (II) acetate trihydrate, 16 mg of cesium carbonate and 10 ml of octadecene (measured with a 5 ml mechanical pipette) were combined in air in a 25 ml 3-neck flask (one of the side necks is used as a glass finger for a thermocouple, and is filled with 0.5 ml of octadecene as a heat transfer medium). The flask with the mixture was equipped with a magnetic stirrer, and the open side neck was capped with a silicone septum and connected to a Schlenk line via a condenser that was inserted into the central neck. It was then placed into the heating mantle on top of a stirring plate. The vacuum was applied first at room temperature for ~5 minutes as a pre-degassing step. Within a few minutes, the contents of the flask were heated to 115 °C under stirring and were kept at that temperature, under vacuum, for approximately one 1 hr. The vacuum was ~50-70 mbar, as was measured with a digital vacuum gauge.

2$^{\text{nd}}$ step, Ligands: In the glovebox, 1 ml of anhydrous toluene was added to 443 mg of DiD-DAm in a 4 ml glass vial, which was then placed on a preheated hot plate (set at 150 °C) until all the DiD-DAm dissolved (m.p. = 45-47 °C). Next, 1.5 ml of the degassed oleic acid was added to the DiD-DAm solution using a 5 ml mechanical pipette. The resulting mixture of ligands was shaken by hand, yielding a clear and colorless solution. The ligand solution was transferred into a 5 ml disposable syringe equipped with a 21G needle, which was then removed from the glovebox.

After the metal salts had degassed (1$^{\text{st}}$ step above), the flask with metal salts in ODE was switched from being under vacuum to being under nitrogen flow, and the ligand mixture in toluene was injected. After adding the ligands, the reaction mixture was kept at 115 °C under stirring until all of the metal salts dissolved (~15-20 minutes), yielding a clear, colorless solution without any visible solids inside. Next, the temperature controller was set to 80 °C (the injection temperature), and the reaction mixture was allowed to cool and stabilize at 80 °C.

3$^{\text{rd}}$ step, Injection of benzyol bromide: In the glovebox, 50 uL of benzyol bromide (measured with a 100 uL mechanical pipette) was mixed with 500 uL of degassed ODE (measured with a 1000 uL mechanical pipette) in a 4 ml glass vial; the mixture was shaken by hand and filled into a 3 ml disposable syringe equipped with a 21G needle. The benzyol bromide solution was taken outside the glovebox, and injected into the mixture of metal salts and ligands at 80 °C under stirring. Upon the injection of the benzyol bromide precursor, the reaction mixture immediately turned from being clear and colorless to being clear and yellow (which is characteristic of CsPbBr$_3$ NCs). After the injection, ~15 seconds were counted with a timer, and the reaction was quenched by replacing the heating mantle with a water bath (at ~20 °C). The reaction was left to cool until it reached ~40 °C, after which the water bath was removed. During both injection and cooling, the reaction was kept under a nitrogen atmosphere.

4$^{\text{th}}$ step, Isolation of nanocubes: Once the reaction had cooled down to near room temperature, the flask was opened in air and the contents were transferred into a 40 ml vial. 3 ml of anhydrous ethyl acetate was then added to the vial, followed by anhydrous ethyl acetate until the mixture turned turbid. Note that the total volume of ethyl acetate needed for nanocrystal precipitation depends on the size of the nanocubes. For the injection temperature and growth time described here (80 °C and ~15 seconds, respectively), it took ~20-30 ml of ethyl acetate to initiate nanocrystal agglomeration (mixture turns turbid). When agglomeration started, the mixture was centrifuged at 5000 rpm for 10 minutes, yielding yellow precipitate on the walls of the vial and a yellow supernatant. The supernatant was discarded and the precipitate was dispersed in a few ml of toluene for characterization and further experiments (such as self-assembly).
2. Amine-free synthesis of CsPbBr₃ NCs

Figure S1. Amine free synthesis of CsPbBr₃ NCs; a) TEM image b) XRD pattern and c) UV-Vis absorption and PL spectra. Bulk pattern for CsPbBr₃ in b) has Reference code 96-451-0746. Syntheses was carried out as follows: the amount of each precursor used was 0.2mmol of PbAc₂·3H₂O, 0.05mmol of Cs₂CO₃, 4.75mmol of OA; the reaction temperature was 80 °C; 50 µl of benzoyl bromide was diluted in 0.5ml of octadecene; the reaction time was 15 seconds.

Figure S2. a-b) TEM images, c) XRD patterns, d) absorption and PL spectra of CsPbBr₃ NCs synthesized without any amine. The syntheses were carried out as follows: the amount of each precursor used was 0.2mmol of PbAc₂·3H₂O, 0.05mmol of Cs₂CO₃, two different amounts of OA were used (3 mmol and 6 mmol, respectively); the reaction temperature was 80 °C; 50 µl of benzoyl bromide was diluted in 0.5ml of octadecene; the reaction time was 15 seconds.
3. Photophysical properties of CsPbBr$_3$ nanocubes synthesized by using various secondary amines.

**Table S1.** The summary of the PL, PLQY and life time measurements of CsPbBr$_3$ nanocubes prepared using secondary amines with various chain lengths.
4. Synthesis of 5.1 nm CsPbBr₃ nanocubes by using dioctadecylamine (DODAm) at 50 °C

Figure S4. CsPbBr₃ nanocubes synthesized using DODAm. The synthesis was carried out using 0.2 mmol PbAc₂·3H₂O, 0.05 mmol Cs₂CO₃, 4.75 mmol of oleic acid, and 1.25 mmol of dioctadecylamine (DODAm) at an injection temperature of 50 °C. a) TEM image of CsPbBr₃ nanocubes and b) absorbance and PL spectra.
5. Controlling the size of CsPbBr$_3$ nanocubes by adjusting the reaction temperature

**Figure S5.** Representative TEM images (a-h), optical absorption and PL spectra (i-l) of CsPbBr$_3$ NCs synthesized by using 1.25 mmol of DDAm and 4.75 mmol of oleic acid at various injection temperatures. Reaction temperatures are indicated in panels (a-h). For each sample, two representative TEM images, at two different magnifications, are reported. Each row of panels refers to the same sample. For example, for the NCs synthesized at 80°C, panels (a-b) are representative TEM images at two different magnification, while the corresponding optical data are reported in panel i).
Effect of the oleic acid concentration on the formation of CsPbBr$_3$ nanocubes

Figure S6. Representative TEM images (a-d), optical absorption and PL spectra (e-h) of CsPbBr$_3$ NCs synthesized using 1.25 mmol of DDDAm and various concentrations of oleic acid, at an injection temperature of 80 °C. Each row of panels refers to the same NC sample. For example, for the NCs synthesized at 1.25 mmol OAc, panel (a) is a representative TEM image, while the corresponding optical data are reported in panel e).
7. Control syntheses of CsPbBr$_3$ NCs in the presence of primary vs. secondary aliphatic amines of the same chain length under similar reaction conditions

Figure S7. The syntheses were carried out using 0.2 mmol of PbAc$_2\cdot$3H$_2$O, 0.05 mmol Cs$_2$CO$_3$, 4.75 mmol oleic acid, and 1.25 mmol of corresponding primary or secondary amines at an injection temperature of 100 °C. TEM images, absorption and PL spectra, and photographs of CsPbBr$_3$ NCs under ambient and UV light. These nanocrystals were synthesized with a,c) dodecylamine and b,d) didodecylamine (DDDAm), respectively.

8. XRD patterns of CsPbBr$_3$ NCs prepared by using primary amines

Figure S8. XRD patterns of CsPbBr$_3$ NPLs synthesized using primary amines: a) oleylamine and b) dodecylamine.
9. Synthesis carried out with dodecylamine and didodecylamine in the absence of Cesium carbonate

![Dodecyl amine](image1) ![Didodecylamine](image2)

**Figure S9.** Photographs of vials containing the crude solution of syntheses carried out using either dodecylamine (a) or didodecylamine (DDDAm) (b) in the absence of a Cs⁺ precursor, while all other reaction conditions were kept the same: the syntheses were carried out using 0.2 mmol of PbAc₂·3H₂O, 4.75 mmol OA, and 1.25 mmol of corresponding primary or secondary amines, at an injection temperature of 100 °C. No precipitate was collected in vial (b) and the reaction mixture remained clear and colorless.

![Figure S10](image3)

**Figure S10.** a) TEM image of layered lead bromide perovskite, b) XRD pattern, and c) absorbance and PL spectra.
10. Control syntheses of CsPbBr$_3$ carried out under secondary amine-rich conditions

**Figure S11.** The synthesis was carried out by using 0.2 mmol PbAc$_2$·3H$_2$O, 0.05 mmol Cs$_2$CO$_3$, 3 mmol of oleic acid (OA), 5 mmol (a four-fold excess compared to the standard procedure) of didodecylamine (DDDAm) and an injection temperature of 80 °C. a) TEM image of the resulting CsPbBr$_3$ nanocubes, b) XRD pattern showing the absence of other cesium lead bromide phases, and c) absorbance and PL spectra. The additional peaks other than orthorhombic CsPbBr$_3$ perovskite phase in the XRD patterns are due to an excess of unreacted DDDAm in the sample and can be indexed accordingly.

11. Stability of CsPbBr$_3$ nanocubes against conversion to Cs$_4$PbBr$_6$ in the presence of excess of didodecylamine as compared with the excess of oleylamine

**Figure S12.** Absorption and PL spectra of the CsPbBr$_3$ nanocubes synthesized in the presence of didodecylamine (DDDAm) are shown in green. The overlaid red absorption and PL spectra were measured after an excess of DDDAm was added to the toluene dispersion of the nanocubes. The black shaded absorption spectrum was measured after an identical toluene dispersion of initially CsPbBr$_3$ nanocubes was mixed with an excess of oleylamine. The photographs in the insets show the resulting mixtures under UV light. An excess of oleylamine triggers the complete conversion of emissive CsPbBr$_3$ nanocubes to non-emissive CS$_5$PbBr$_6$ phases, while DDDAm is inactive for that transformation.
12. Solubility of lead (II) bromide in the presence of primary and secondary amines

It should be noted that the solubility of PbX$_2$ salts in the mixture that contains both acid (oleic acid) and a primary amine (oleylamine), which is typically used for the synthesis of CsPbX$_3$ NCs, is highly limited by the formation of the ammonium carboxylate salt, as discussed in a previous work from our group.$^1$ For primary amines in the presence of excess amine, this salt can undergo dissociation by homoassociation (i.e. hydrogen bonding between a base and its conjugate acid),$^2$ which can be described as:

\[ BH^+ \cdots A^- + B \rightleftharpoons (BH^+ \cdots B)A^- \]

in which $BH^+ \cdots A^-$ is the ammonium carboxylate salt, formed by the acid $AH$ (oleic acid in this case) and the base $B$ (the primary amine in this case). Homoassociation (the formation of $BH^+ \cdots B$), in turn, promotes the solvation of PbX$_2$. Homoassociation cannot take place with secondary aliphatic amines when substituents are bulkier than the methyl groups.$^2$ In the figure below is can be seen how PbBr$_2$, for example, is easily dissolved in an oleic acid-octylamine mixture, but not in an oleic acid-dioctylamine mixture or in oleic acid alone.

![Figure S13. Solubility of lead bromide in primary (left vial) and secondary (right vial) amines with the same hydrocarbon chain length. Experimental details: 72 mg of PbBr$_2$, 3 mmol of amine (octylamine or dioctylamine), 3 mmol of oleic acid, 5 ml of octadecene were combined in a 20 mL vial, heated up to 130 $^\circ$C on a hotplate and kept at that temperature for 30 minutes.](image-url)
13. $^1$H NMR spectra of the mixtures of oleic acid and dodecylamine

**Figure S14.** Selected regions of the $^1$H NMR spectra of dodecylamine (DDAm), oleic acid (OA) and their various mixtures in toluene-d8 at various molar %.
