Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company’s public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Identification of non-covalent SARS-CoV-2 main protease inhibitors by a virtual screen of commercially available drug-like compounds

The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) appeared first in late December of 2019 in Wuhan, China. It has since spread globally, resulting in more than 110 million cases and 2.4 million deaths, with the United States, India and Brazil among the hardest hit nations to date (February 2021). SARS-CoV-2 is now the third highly pathogenic coronavirus to infect humans since the turn of the century, being preceded by SARS-CoV and MERS-CoV. Multiple vaccine trials have been conducted and several vaccines are now approved, but the need for a small molecule therapeutic remains critical, both to treat those who are already infected and for immunocompromised individuals who cannot receive a vaccine. Moreover, antiviral drugs targeting relatively constant viral proteins will be needed as part of the preparation against future coronavirus outbreaks, as vaccines developed against SARS-CoV-2 are likely to be ineffective against future strains. Early in 2020, the X-ray crystal structure of the SARS-CoV-2 main protease (M\text{pro}) was reported. M\text{pro} is known to be a critical component of viral replication, making it an extremely attractive target for antivirals. Unsurprisingly, several computational studies have been conducted to identify inhibitors of M\text{pro} focusing primarily on existing drugs and/or natural products. In contrast, we decided to conduct a virtual screen of all commercially available drug-like molecules, giving a ligand pool with millions of candidates. By restricting our virtual screen to compounds which are already available, any identified hits would be readily available without the need for synthesizing them in-house.

We began our virtual screen by selecting the crystal structure of M\text{pro} bound to an \(\alpha\)-ketoamide inhibitor\(^a\) (PDB 6y2f) as our protein target (Fig. 1). We selected this protein structure as it was the only structure of the SARS-CoV-2 M\text{pro} with a bound drug-like inhibitor at the time (early 2020).

The protein structure was prepared using ChimeraX\(^b\) to remove the inhibitor and water molecules, leaving only the protein chain. The remaining structure was then adjusted to physiological pH (7.4) and converted to the PDBQT format using Open Babel.\(^8\)

We next prepared a library of virtual compounds using the ZINC15 database, which contains more than 230 million compounds. We filtered this initial library by selecting only compounds that were commercially available and applied a series of Lipinski filters to select only drug-like molecules (molecular weight 200–500 g/mol, log P \(\leq 5\), number of rotatable bonds \(\leq 5\), total polar surface area \(\leq 150 \text{Å}^2\), H-bond donors \(\leq 5\), and H-bond acceptors \(\leq 10\)). We further filtered the library to remove PAINS scaffolds,\(^10\) then adjusted the pH of all compounds to 7.4 and compiled the library in PDBQT format. The final library consisted of 9,779,510 compounds.

Since several inhibitors of M\text{pro} have been reported, we next decided to test which of the three docking programs available to us (AutoDock Vina\(^11\), iDock\(^12\) and Smina\(^13\)) gave the best performance using these known inhibitors as a benchmark. We selected a test set of 7 inhibitors with IC\(_{50}\) values spanning 3 orders of magnitude\(^13\,14\) and then used the Spearman correlation coefficient (R\(_s\)) to rank the performance of each docking program (see supporting information, Table S1). We found that the iDock program performed the best (R\(_s\) = 0.745) and selected it for our virtual screen. We then selected the center of our search space as the center of mass of the bound inhibitor \((x = 10.832, y = -0.291, z = 20.731)\) and defined the search area as a 22 Å \(\times\) 22 Å \(\times\) 22 Å cube to encompass the full binding surface. All other parameters of the iDock program were left at default settings, as a recent benchmarking study has found that increasing the settings to make the calculations more time intensive give little to no improvement.\(^15\) After concatenating the results, we selected the top 75 compounds as an initial arbitrary cutoff. These 75 compounds were then upload to Datawarrior\(^16\) where we applied additional drug-like filters (Druglikeness score > 0, DrugScore > 0.25) and removed any identified toxicophores, resulting in 45 hit compounds. We next applied a Tanimoto filter to these 45 compounds based on the FP2 path-based fingerprint\(^17\) using a threshold value of 0.4 to eliminate compounds with high similarity, resulting in a total of 28
unique hit compounds (see supporting information, Fig. S1). The ZINC IDs and several select properties of the top 28 hits (named CP-1, CP-2, etc.) as calculated by DataWarrior are shown in Table 1.

With our hit compounds identified, we began to order them from the associated vendors as indicated by the ZINC database. Due to the SARS-CoV-2 pandemic, however, some commercial vendors reported significant disruption in their transportation networks. As a result of these complications, we were unable to obtain eight of our hit compounds (CP-1, CP-4, CP-6, CP-15, CP-17, CP-18, CP-19, and CP-21). Rather than waiting for these compounds to become available, we decided to proceed to in vitro studies with the remaining 20 compounds.

With our compounds in hand, we next tested their inhibitory activity against MPro. Briefly, a pH 7.3 buffer prepared with 20 mM Tris-HCl, 100 mM NaCl, 1 mM EDTA, and 1 mM DTT was utilized for the inhibitory assay of the hit compounds against SARS-CoV-2 MPro in vitro. The substrate labeled with Dabcyl and Edans at the N and C-terminus, respectively, and comprising the cleavage site of MPro was pipetted into a well with 20 μL of buffer solution followed by the addition of 2.5 μL of the corresponding compound stock solution dissolved in DMSO, resulting in a final concentration of 50 μM in each well (2.5 μL of DMSO was used as the negative control). The protease and compound mixture was incubated at 37 °C for 10 min. Afterwards, 25 μL of FRET substrate dissolved in the reaction buffer at an overall concentration of 20 μM was added into the corresponding wells containing the protease and compound mixture to initiate the reaction. The relative fluorescence units per unit of time (ΔRFU/s) from the linear section of the curve were used for the calculation of the inhibition rate. The inhibition rate was determined by using the formula listed below where $V_{o}$ represents the initial velocity of reaction with inhibitor:

$$\text{Inhibition rate} \% = \left( \frac{V_{o} - V_{i}}{V_{o}} \right) \times 100\%$$

All experiments were performed in triplicate and the values are presented as the means ± the standard deviation (Table 2).

Since compounds CP-13 and CP-25 showed modest activity, we decided to subject them to molecular dynamics (MD) simulations carried out using AMBER18 to examine their ability to remain bound to the putative binding site under equilibrating conditions and also to provide a calculated binding energy at this site. We did not select CP-27 for MD given the large SD associated with its observed inhibition due to auto-fluorescence. Protein-ligand complexes of CP-13 and CP-25 with MPro were subjected to 50 ns production runs at 300 K. Examination of the protein–ligand structure trajectories showed them to be stable throughout the production runs, with minimal reorganization of the ligands at the binding site and general stability of the protein structure. RMSD and potential energy data graphs are provided for CP-25 (Fig. S2) demonstrating that equilibration occurs within the first 35 ns, although a significant decrease in potential energy is not observed in this system. The RMSD-potential energy profile for CP-25 is representative of CP-13 through the production runs, with minimal reorganization of the ligands at the binding site and general stability of the protein structure.

### Table 1

| Compound | ZINC ID       | iDock Score (kcal/mol) | cLogP | HBA | HBD | tPSA (Å²) |
|----------|---------------|------------------------|-------|-----|-----|-----------|
| CP-1     | ZINC000408813176 | -11.37                 | 1.94  | 7   | 3   | 100       |
| CP-2     | ZINC000137246460 | -10.18                 | 2.82  | 6   | 1   | 71        |

| CP-23    | ZINC00092038755 | -9.72                  | 3.52  | 6   | 1   | 66        |
| CP-24    | ZINC00045995522 | -9.71                  | 4.16  | 7   | 0   | 79        |
| CP-25    | ZINC00006757463 | -9.71                  | 3.83  | 7   | 2   | 89        |
| CP-26    | ZINC00035478508 | -9.71                  | 3.64  | 6   | 0   | 87.7      |
| CP-27    | ZINC00218427747 | -9.70                  | 2.24  | 8   | 4   | 124       |
| CP-28    | ZINC00013777264 | -9.69                  | 4.67  | 5   | 0   | 43        |

**Fig. 1.** Crystal structure of MPro (PDB 6y2f). Domain I is shown in orange, Domain II in grey, the connecting loop in yellow, and Domain III in teal. The inhibitor is shown with a green backbone, and the catalytic dyad residues shown with a magenta backbone.
and CP-25 over a 100-ps window at the end of the 50 ns run, using the MM/GBSA method (−29.71 and −26.39 kcal/mol, respectively) and the MM/PBSA method (−23.97 and −18.97 kcal/mol, respectively). Notably the MM/GBSA and MM/PBSA methods both correctly ranked compounds CP-13 and CP-25 based on the experimental %inhibition data which indicates a greater level of inhibition achieved by CP-13.

In conclusion, our virtual screen of nearly 10 million commercially available compounds targeting SARS-CoV-2 Mpro and subsequent viral protease inhibition assay identified two compounds with modest inhibitory activity. The hit compounds, CP-13 and CP-25, are non-covalent inhibitors that bind with minimal reorganization and interact with protein residues primarily through non-polar interactions as indicated by MD simulation. While these compounds are not currently potent enough to advance to the clinic, they provide two additional candidates for development as antivirals to combat COVID-19. These

| Compound | Structure | Inhibition (%) |
|----------|-----------|----------------|
| CP-2     | ![Image](image1.png) | n.d.           |
| CP-3     | ![Image](image2.png) | 6.54 ± 3.60    |
| CP-5     | ![Image](image3.png) | 1.16 ± 6.12    |
| CP-7     | ![Image](image4.png) | 16.57 ± 3.12   |
| CP-8     | ![Image](image5.png) | 6.29 ± 3.32    |
| CP-9     | ![Image](image6.png) | 9.38 ± 6.75    |

| CP-16    | ![Image](image12.png) | 5.21 ± 1.07    |

a  Autofluorescent compound.
b  Values are reported as the means ± SD of three measurements.
compounds could also serve as a template to synthetically attach electrostatic “warheads” which have led to the development of powerful covalent inhibitors of Mpro. While additional improvement in potency is needed, we believe these findings help address the critical need for new treatment options to combat the pandemic as our identification of commercially available compounds with inhibitory activity against Mpro is a useful starting point for further optimization, either through purchasing or synthesizing additional analogues.

Declaration of Competing Interest
