A Straightforward Synthesis of Polyketides via Ester Dienolate Matteson Homologation

Oliver Andler and Uli Kazmaier*[a]

Abstract: Application of ester dienolates as nucleophiles in Matteson homologations allows for the stereoselective synthesis of highly substituted \(\alpha,\beta\)-unsaturated \(\delta\)-hydroxy carboxylic acid motifs found in polyketide natural products. The protocol is rather flexible and permits the introduction of substituents and functionalities also at those positions which are not accessible by the commonly used aldol reaction. Therefore, this ester dienolate Matteson approach is an interesting alternative to the “classical” polyketide syntheses.

Polyketides are an enormously large group of natural products found widespread in linear as well as in cyclic form as macrocycles.[1] Biosynthetically, the polyketides are formed via decarboxylative Claisen condensation of activated malonate, followed by reduction of the \(\beta\)-ketoester formed.[2] Therefore, classical polyketides often contain \(O\)-functionalities at 3,5,7 positions. Double bonds can be obtained via dehydration, and their reduction gives rise to linear unsubstituted carbon chains, comparable to fatty acids. The use of activated methyl malonate results in the introduction of methyl groups at positions 2,4,6 of the polyketide chains, while anomalous substitution pattern are generally the result of post-translational modifications.[3] The combination of the involved polyketide synthases (PKS) with modules of nonribosomal peptide synthetases (NRPS) gives access to peptide-polyketide hybrids[4] such as jasplakinolide,[5] miuraenamide[6] or lagunamide[7] (Figure 1), to name only a few. Many of these natural products have highly interesting biological activities and might be good candidates for the development of new antibiotics or anticancer agents.[8] Therefore, it is not surprising that many efforts have been undertaken in the development of asymmetric syntheses of these natural products.[9]

The most popular approaches take advantage of asymmetric aldol reactions, in all their variations, to generate directly the polyketide substitution pattern.[10] An alternative approach uses asymmetric allylations/crotylations in combination with oxidative double bond cleavage to generate the same structural motifs.[11] No question, these protocols are straightforward for the syntheses of classical polyketides, but are less suited for posttranslational modified natural products, having \(O\)- or \(C\)-functionalities at “unusual” positions.

Our group is also involved in the synthesis of biological active natural products, focusing on cyclic peptides and peptide-polyketide hybrids.[12] To become independent of the aldol-motif we developed recently a synthesis of lagunamide based on a Matteson homologation.[13] This stereoselective prolongation of chiral boronic esters was introduced by Donald Matteson already 40 years ago.[14] Key step of this protocol is the highly stereoselective formation of a \(\alpha\)-chloro boronic ester A (Scheme 1) which can be subjected to nucleophilic substitution under \(S_N2\)-conditions with a wide range of nucleophiles,[15] such as Grignard reagents, alkoxides or certain enolates.[16, 17] This allows for the stepwise stereoselective incorporation of substituents and functionalities into a growing carbon chain. For a long time most synthetic applications of this elegant method were reported by Matteson himself,[18] but in the last years it found several nice applications in natural product[19] or drug syntheses.[20] Aggarwal developed a version where the stereochemical outcome of each prolongation step can be controlled by using spartein as a chiral ligand.[19, 21]

We applied the classical Matteson approach in the synthesis of the polyketide fragment of lagunamide A from ester B,[13] where all four stereogenic centers were controlled by the chiral diol in the boronic ester. Key intermediate was the prolonged \(\alpha\)-chloro boronic ester C which was oxidized to the cor-

actions yield mainly the α-product,\textsuperscript{[25]} while the γ-products are obtained under thermodynamical conditions.\textsuperscript{[26, 27]} Mukaiyama aldol reactions using vinylogous silyketenacetals as nucleophiles also give a higher ratio of γ-substitution product,\textsuperscript{[30]} while this approach was used frequently in polyketide syntheses,\textsuperscript{[29]} for example, in a synthesis of lagunamide A and related compounds.\textsuperscript{[30]} To the best of our knowledge dienolates have never been applied in Matteson homologations so far, and only two publications describe the use of simple ester enolates.\textsuperscript{[14]}

To figure out if the dienolates can be used in Matteson homologations at all we investigated the reaction of crotylesters with phenyl ethyl boronic ester 1 (Table 1). First experiments were carried out under “typical Matteson conditions” using CHCl\textsubscript{3}Li as a nucleophile. Crotonic esters cannot be deprotonated with LDA, because 1,4-addition of the amide is a too fast process,\textsuperscript{[23]} but this side reaction can be suppressed by addition of HMPA.\textsuperscript{[23]} To avoid the usage of this nasty reagent we decided to use DMPU (N,N\textendash dimethylpropylene urea) instead.\textsuperscript{[21]}

But no desired homologation product could be observed, only a mixture of undefined products. We assumed, that the reactivity of the α-chloro boronic ester might not be high enough and decided to switch to the corresponding α-bromo derivative. These brominated esters are more reactive, but show also a higher tendency for epimerization, causing products with lower stereoselectivity.\textsuperscript{[25]} Therefore, it is recommended to use such esters without purification and storage to avoid decomposition and epimerization. With α-bromo boronic ester 2, the desired product could be obtained in acceptable yield, although as a mixture of the linear (E)-configured γ-product (3a) and the branched α-product (3a') (as diastereomeric mixture) (Table 1, entry 1). After oxidation, the desired δ-hydroxylated unsaturated ester could be obtained in pure form. Ethyl crotonate gave almost the same result as the tert-butylester (entry 2). No reaction was observed with silyketenacetals, even in the presence of Lewis acids. Therefore, we decided to investigate the influence of the counter ion, which has an influence in aldol reactions.\textsuperscript{[24]} But in our case the addition of copper salts had no influence on the α/γ-selectivity, only the yield

was obtained in good (Entry 4). Addition of another methyl group at the γ-position (4e) had no influence on the yield on the previous example, only in case of the methyl ester 5c the yield was a little lower (Entry 3). In all examples only the formation of the (E)-isomer was observed. To investigate the scope and limitations of this protocol also substituted tiglic esters 4d-f were evaluated. Introduction of an additional methyl group on the double bond (4d) was well accepted and the tetra substituted double bond in 5d was obtained in good (Entry 4). Addition of another methyl group at the γ-position (4e) had no influence on the yield but on the regioselectivity (Entries 5 and 6). The γ/α-selectivity of 5e was significantly lower, compared to the examples without substituent on the γ-position, but was still in a synthetically useful range. While the α-product was an inseparable mixture of diastereomers and (E/Z)-isomers, the γ-product was obtained in good diasteroselectivity, especially in the case of the ethyl ester 5f (Entry 5). The product mixtures were analyzed after oxidation, the corresponding alcohols could be separated by flash chro-
matography. It should be mentioned that the yields given in tables 1 and 2 are isolated yields after chromatography.

All boronic esters 5 were oxidized to the corresponding unsaturated δ-hydroxysterter. Depending on the oxidation proto-
col different products become available. Using “typical” oxidation conditions methyl ester 5a was also hydroyzed to the free carboxylic acid 6c (Scheme 2). In contrast, under the same conditions tert-butyl esters 5a are not affected. Using Na2CO3 as a milder base also the ethyl ester of 5b remains untouched. In the last two cases the hydroxy esters 6a and 6b could not be separated from the chiral diol used as auxiliary in the boronic ester. But this problem can be solved by adding commercially available methyl boronic acid forming the chiral methyl boronic ester B (Scheme 1), which can be used again in Matte-

son homologations. In principle, the original boronic esters used in the homologation sequence can be “recovered”, what makes this protocol rather economic. All alcohols 6 were ob-
tained with an ee > 90% clearly indicating that no significant epimerization in the α-bromo boronic ester occurred.

Finally we reacted tiglic ester 4b with a series of different boronic esters (Scheme 2). In contrast, under the same conditions tert-butyl esters 5a are not affected. Using Na2CO3 as a milder base also the ethyl ester of 5b remains untouched. In the last two cases the hydroxy esters 6a and 6b could not be separated from the chiral diol used as auxiliary in the boronic ester. But this problem can be solved by adding commercially available methyl boronic acid forming the chiral methyl boronic ester B (Scheme 1), which can be used again in Matte-

son homologations. In principle, the original boronic esters used in the homologation sequence can be “recovered”, what makes this protocol rather economic. All alcohols 6 were ob-
tained with an ee > 90% clearly indicating that no significant epimerization in the α-bromo boronic ester occurred.

Finally we reacted tiglic ester 4b with a series of different boronic esters (see Supporting Information) to illustrate the scope and applicability of this protocol (Figure 2). Linear as well as branched and functionalized boronic esters can be used giving yields in the range of 61–78%, independent of the substitution pattern and the chiral auxiliary used. Only one set of signals are observed in the NMR spectra of the purified products 7, indicating a high diasteroselectivity.

As a proof of concept we also synthesized a protected poly-
eketide fragment of epi-lagunamide A starting from known boronic ester 8. Homologation of 8 with CHBrLi followed by re-
action with the dienolate of ethyl tiglate provided 9 in high yield, which was then oxidized to the desired polyketide frag-
ment 10. Moreover, we recovered the chiral auxiliary DICHED after oxidation (Scheme 3).

In conclusion, we could show that ester dienolates are good nucleophiles for Matteson homologations. Especially enolates of tiglic esters give excellent regio- and stereoselectivities, and in combination with a subsequent oxidation of the prolonged
