LOCAL CONVERGENCE OF AN ALGORITHM FOR SUBSPACE IDENTIFICATION FROM PARTIAL DATA

LAURA BALZANO* AND STEPHEN J. WRIGHT†

Abstract. GROUSE (Grassmannian Rank-One Update Subspace Estimation) is an iterative algorithm for identifying a linear subspace of \( \mathbb{R}^n \) from data consisting of partial observations of random vectors from that subspace. This paper examines local convergence properties of GROUSE, under assumptions on the randomness of the observed vectors, the randomness of the subset of elements observed at each iteration, and incoherence of the subspace with the coordinate directions. Convergence at an expected linear rate is demonstrated under certain assumptions. The case in which the full random vector is revealed at each iteration allows for much simpler analysis, and is also described. GROUSE is related to incremental SVD methods and to gradient projection algorithms in optimization.

Key words. Subspace Identification, Optimization

1. Introduction. We seek to identify an unknown subspace \( S \) of dimension \( d \) in \( \mathbb{R}^n \), described by an \( n \times d \) matrix \( \bar{U} \) whose orthonormal columns span \( S \). Our data consist of a sequence of vectors \( v_t \) of the form

\[
v_t = \bar{U} s_t,
\]

where \( s_t \in \mathbb{R}^d \) is a random vector whose elements are independent and identically distributed (i.i.d.) in \( \mathcal{N}(0,1) \). Critically, we are able to observe only a subset \( \Omega_t \subset \{1,2,\ldots,n\} \) of the components of \( v_t \).

GROUSE \cite{balzano2013local, balzano2014local} (Grassmannian Rank-One Update Subspace Estimation) is an algorithm that generates a sequence \( \{U_t\}_{t=0,1,\ldots} \) of \( n \times d \) matrices with orthonormal columns with the goal that \( R(U_t) \to S \) (where \( R(\cdot) \) denotes range). Partial observation of the vector \( v_t \) is used to update \( U_t \) to \( U_{t+1} \). We present GROUSE (slightly modified from earlier descriptions) as Algorithm 1.

1.1. Applications of Subspace Identification. Subspace identification problems arise in a great variety of applications. They are the simplest form of the more general class of problems in which we seek to identify a low-dimensional manifold in a high-dimensional ambient space from a sequence of incomplete observations. Subspace identification finds applications in medical \cite{balzano2014local} and hyperspectral \cite{balzano2013local} imaging, communications \cite{balzano2014local}, source localization and target tracking in radar and sonar \cite{balzano2013local}, computer vision for object tracking \cite{balzano2014local}, and in control for system identification \cite{balzano2013local, balzano2014local}, where one is interested in estimating the range space of the observability matrix of a system. Subspaces have also been used to represent images of a single scene under varying illuminations \cite{balzano2014local} and to model origin-destination flows in a computer network \cite{balzano2014local}. Environmental monitoring of soil and crop conditions \cite{balzano2013local}, water contamination \cite{balzano2014local}, and seismological activity \cite{balzano2013local} can all be summarized efficiently by low-dimensional subspace representations.

1.2. GROUSE. Each iteration of the GROUSE algorithm (Algorithm 1) essentially performs a gradient projection step onto the Grassmannian manifold of subspaces of dimension \( d \), based on the latest partially observed sample \( [v_t]_{\Omega_t} \) of the
random vector $v_t \in \mathcal{S}$. In this description, we use $[U]_\Omega$ to denote the row submatrix of the $n \times d$ matrix $U$ corresponding to the index set $\Omega \subset \{1,2,\ldots,n\}$. Similarly, $[z]_\Omega$ denotes the subvector of elements of $z \in \mathbb{R}^n$ corresponding to elements of $\Omega$. We use $|\Omega|$ to denote cardinality of the set $\Omega$ and $\Omega_c$ to denote the complement $\{1,2,\ldots,n\} \setminus \Omega$.

**Algorithm 1** GROUSE: Partial Data

Given $U_0$, an $n \times d$ matrix with orthonormal columns, with $0 < d < n$;
Set $t := 1$;
repeat
  Draw a random subset $\Omega_t \subset \{1,2,\ldots,n\}$ and and observe $(v_t)_{\Omega_t}$ where $v_t \in \mathcal{S}$;
  if the eigenvalues of $[U_t]^T[U_t]_{\Omega_t}$ lie in the range $[0.5|\Omega_t|/n, 1.5|\Omega_t|/n]$ then
    Define $w_t := \arg \min_{w} \| [U_t]_{\Omega_t} w - [v_t]_{\Omega_t} \|^2$;
    Define $p_t := U_t w_t$; $[r_t]_{\Omega_t} := [v_t]_{\Omega_t} - [p_t]_{\Omega_t}$; $[r_t]_{\Omega_t^c} := 0$; $\sigma_t := \|r_t\| / \|p_t\|$;
    Choose $\eta_t > 0$ and set
    \[
    U_{t+1} := U_t + \left[ (\cos(\sigma_t \eta_t) - 1) \frac{p_t}{\|p_t\|} + \sin(\sigma_t \eta_t) \frac{r_t}{\|r_t\|} \right] \frac{w_t^T}{\|w_t\|}.
    \] (1.2)
  end if
  $t := t + 1$;
until termination

This description in Algorithm 1 differs from that of [3] only in that the following condition is required for the eigenvalues of $[U_t]^T[U_t]_{\Omega_t}$:

$$
\lambda_i([U_t]^T[U_t]_{\Omega_t}) \in \left[ 5 \frac{|\Omega_t|}{n}, 1.5 \frac{|\Omega_t|}{n} \right], \quad i = 1,2,\ldots,d,
$$ (1.3)

where $\lambda_i(\cdot)$ denotes the $i$th eigenvalue (in decreasing order). A consequence is that

$$
\|([U_t]^T[U_t]_{\Omega_t})^{-1}\| \leq \frac{2n}{|\Omega_t|}.
$$ (1.4)

As we see later, this condition ensures that the sample $\Omega_t$ is such that $[v_t]_{\Omega_t}$ captures useful information about $\mathcal{S}$; if it is not satisfied, the weight vector $w_t$ may not accurately reflect how the latest observation $[v_t]_{\Omega_t}$ is explained by the current basis vectors (the columns of $[U_t]_{\Omega_t}$). Since we need to factor the matrix $[U_t]_{\Omega_t}$ in order to calculate $w_t$, and since we have typically that $d \ll n$, the marginal cost of determining or estimating the singular values of $[U_t]_{\Omega_t}$ and checking the condition (1.4) is not excessive. We show in our analysis that the condition (1.3) is satisfied at most iterations.

We note several elementary facts about the vector quantities that appear in GROUSE. Let $P_{R(\cdot)}$ denote the projection operator onto the range, and $P_{N(\cdot)}$ denote the projection onto the nullspace of a matrix. Since

$$
[p_t]_{\Omega_t} = P_{R([U_t]_{\Omega_t})}([v_t]_{\Omega_t}), \quad [r_t]_{\Omega_t} = P_{N([U_t]^T_{\Omega_t})}([v_t]_{\Omega_t}),
$$

we have that

$$
p_t^T r_t = [p_t]^T_{\Omega_t^c} [r_t]_{\Omega_t} = 0
$$ (1.5)
and
\[ \| p_t + r_t \|^2 = \| p_t \|^2 + \| r_t \|^2. \] (1.6)

By orthonormality of the columns of \( U_t \), we also have that
\[ \| p_t \| = \| w_t \|. \] (1.7)

### 1.3. GROUSE in Context.

To gain some intuition about GROUSE, and to relate it to other algorithms from optimization and linear algebra, we consider the regime in which the iterates \( U_t \) are close to identifying the correct subspace \( S \) (so that \( \| r_t \| \ll \| p_t \| \)) and choose the steplength \( \eta_t \) so that
\[ \sin \sigma_t \eta_t = \| r_t \| / \| p_t \|. \] (1.8)

Since \( 1 - \cos \sigma_t \eta_t = O(\| r_t \|^2 / \| p_t \|^2) \), by multiplying both sides of (1.2) by \( w_t \), and using (1.7), we have that
\[ U_{t+1}w_t = U_tw_t + \frac{\| r_t \|}{\| p_t \|} \frac{w_t^T w_t}{\| w_t \|} + O\left( \frac{\| r_t \|^2}{\| p_t \|^2} \right) = p_t + r_t + O\left( \frac{\| r_t \|^2}{\| p_t \|^2} \right). \]

It follows from the definition of \( r_t \) that
\[ [U_{t+1}w_t]|_{\Omega_t} \approx [p_t + r_t]|_{\Omega_t} = [v_t]|_{\Omega_t}, \] (1.9a)
\[ [U_{t+1}w_t]|_{\Omega_t^c} \approx [p_t + r_t]|_{\Omega_t^c} = [U_tw_t]|_{\Omega_t^c}, \] (1.9b)

where \( \Omega_t^c : \{1, 2, \ldots, n\} \setminus \Omega_t \). Moreover, in any direction \( z \) orthogonal to \( w_t \), we have \( U_{t+1}z = U_tz \). Thus, the update (1.2) has the effect of (approximately) matching the newly revealed information \([v_t]|_{\Omega_t} \) along the direction \( w_t \), while leaving the values of \( U_tw_t \) almost unchanged in the non-revealed components \( \Omega_t^c \), and making no change at all in the remaining \((d - 1)\)-dimensional subspace \( \{z \mid w_t^T z = 0\} \). In this sense, (1.2) is a “least-change” update, leaving the current iterate \( U_t \) undisturbed as far as possible, but making just enough of a change to match the new information. The least-change strategy is key to the development of quasi-Newton methods for optimization [14, Chapter 6], in which low-rank, least-change updates are made to approximate Hessian matrices, to match the curvature information gained in each step.

The relationship of GROUSE to gradient projection becomes clearer when we define the following measure of inconsistency between \( R(U_t) \) and \( S \), based on the information revealed in \([v_t]|_{\Omega_t} \):
\[ \mathcal{E}(U_t) := \min_w \| [U_t]|_{\Omega_t} w - [v_t]|_{\Omega_t} \|^2. \]

It can be shown that
\[ \frac{d\mathcal{E}}{dU_t} = -2r_tw_t^T. \]

With the choice (1.8) of \( \eta_t \), we have from (1.2) that
\[ U_{t+1} = U_t + \frac{1}{\| p_t \|^2} r_tw_t^T + O\left( \frac{\| r_t \|^2}{\| p_t \|^2} \right), \]
so that the GROUSE step is a step in the negative gradient direction for $E$, projected onto the space of $n \times d$ matrices with orthonormal columns.

GROUSE is related too to an incremental singular value decomposition (iSVD) approach that maintains an approximation $U_t$ with orthonormal columns, and iterates in the following way. First, the new random vector $v_t$ is appended to $U_t$ to form an $n \times (d+1)$ matrix, with missing elements of $v_t$ “imputed” from the current estimate $U_t$ and the weight vector $w_t$ obtained as in GROUSE. Second, the SVD of this expanded matrix is computed, and the first $d$ columns of its left factor (an $n \times (d+1)$ matrix with orthonormal columns) are taken as the new iterate $U_{t+1}$. (The final column is discarded.) It is shown in [5] that for a certain choice of steplength parameter $\eta_t$ in GROUSE, the iSVD and GROUSE algorithms are equivalent.

In our analysis below, we use the following generalization of (1.8) for the choice of $\eta_t$:

$$\sin \sigma_t \eta_t = \alpha_t \frac{\|r_t\|}{\|p_t\|},$$

(1.10)

where $\alpha_t \in (0, 2)$ is a user-defined “fudge factor.” We show that the best asymptotic results are obtained by setting $\alpha_t \equiv 1$.

1.4. Summary of Results. Our main result is expected local linear convergence of the sequence of subspaces $\{R(U_t)\}$ to $S$. This section outlines the assumptions needed to prove our result and discusses their relevance to computational experience.

We recall the assumption that the observation vector $v_t$ has the form $\bar{U}s_t$ (1.1), with the elements of $s_t$ being i.i.d normal with zero mean and identical variance. We assume too that the set $\Omega_t$ of observed elements of $v_t$ is chosen independently at each iteration.

The discrepancy between the $d$-dimensional subspaces $R(U_t)$ and $S$ is measured in terms of the $d$ principal angles between these subspaces [17, Chapter 5], defined by

$$\cos \phi_i(U_t, \bar{U}) = \sigma_i(\bar{U}^TU_t), \quad i = 1, 2, \ldots, d,$$

(1.11)

where $\sigma_i(\bar{U}^TU_t)$, $i = 1, 2, \ldots, d$ are the singular values of $U_t^T\bar{U}$. The quantity $\epsilon_t$ defined by

$$\epsilon_t := \sum_{i=1}^d \sin^2 \phi_i(U_t, \bar{U}) = \sum_{i=1}^d (1 - \sigma_i^2(U_t^TU_t)) = d - \|\bar{U}^TU_t\|_F^2,$$

(1.12)

is central to our analysis. We show that for small $\epsilon_t$, we have

$$\epsilon_{t+1} \approx \epsilon_t - \frac{\|r_t\|^2}{\|w_t\|^2},$$

(1.13)

and that the expected value of the decrease $\|r_t\|^2/\|w_t\|^2$ is bounded below by a small multiple of $\epsilon_t$, provided that the eigenvalue check (1.3) is satisfied. (Higher-order terms complicate the analysis considerably.)

A critical assumption, made precise below, is incoherence of the subspace $S$ with respect to the coordinate directions. Concepts of incoherence have been well studied in the context of compressed sensing (see for example [7]). If $S$ were to align closely with one or two principal axes, then observation subsets $\Omega_t$ that did not include the corresponding index would be missing important information about $S$. We would
need to choose larger sample sets \( \Omega_t \) (of size \(|\Omega_t|\) related to \(n\)), or to take many more iterations, in order to have a good chance of capturing the components of \(v_t\) that align with \(S\).

Our analysis requires another kind of incoherence too. We assume that the error in \(U_t\) revealed by the observation vector — the part of \(v_t\) that is not explained by the current iterate \(U_t\) — is usually incoherent with respect to the coordinate directions. (Our computations indicate that such is the case.) This incoherence measure is denoted by \(\mu(x_t)\), where \(x_t := (I - U_t U_t^T)v_t\), and our assumption on this quantity is spelled out in Lemma 2.9.

High-probability results play a key role in the analysis. Our lower bound on the quantity \(\|r_t\|^2/\|w_t\|^2\) in (1.13), for instance, is not proved to hold at every iteration but only at a substantial majority of iterations. In fact, it is possible that \(\epsilon_{t+1} > \epsilon_t\) for some \(t\); the sequence \(\{\epsilon_t\}\) may not decrease monotonically.

We state at the outset that the expected linear convergence behavior is proved to hold in only a limited regime, that is, the main theorem requires \(\epsilon_t\) to be quite small and each \(|\Omega_t|\) to be on the order of \(d(\log d)(\log^2 n)\) in order for the claimed linear rate to be observed. This is not surprising, given that the analysis is based on conservative bounds associated with the effects of sampling. The observed linear convergence rate, roughly speaking, is a factor of \((1 - Xq/(nd))\) per iteration, where \(q\) is a lower bound on \(|\Omega_t|\) and \(X\) is some number not too much less than one. We see in Section 4 that this rate appears to hold in a much wider regime than the analysis would strictly predict, both for much smaller \(|\Omega_t|\) and for much larger \(\epsilon_t\). In fact, the same “mismatch” between theory and practice of local convergence is seen in many optimization algorithms. We point out too that the mismatch largely disappears in the full-data case, where \(\Omega_t = \{1, 2, \ldots, n\}\) for all \(t\). In this case, the theoretical restrictions on \(\epsilon_t\) are mild, incoherence is irrelevant, and the predicted convergence behaviour matches closely the computational observations.

1.5. Outline. Section 2 contains the proof of our claim of expected linear convergence. This long section is broken into subsections, with a “roadmap” given at the start. Section 3 analyzes the full-data case in which \(\Omega_t \equiv \{1, 2, \ldots, n\}\). Many of the complications of the general case vanish here, but the specialized analysis holds some interest and convergence still occurs only in an expected sense, because of the random nature of the observation vectors \(v_t\).

Notation. As noted earlier, we use \(N(\cdot)\) to denote the null space (kernel) of a matrix and \(P_T\) to denote projection onto a subspace \(T\).

The notation \(\|\cdot\|\) (without subscript) on either vector or matrix indicates \(\|\cdot\|_2\). Recall that the Frobenius norm is related to \(\|\cdot\|_2\) by the following inequalities:

\[
\|A\|_2 \leq \|A\|_F \leq \sqrt{r}\|A\|_2,
\]

where \(r\) is the rank of \(A\). We note too that the norms \(\|\cdot\|_2\) and \(\|\cdot\|_F\) are invariant under orthogonal transformations of the matrix argument.

We drop the subscripts \(t\) frequently during the paper, when it causes no confusion to do so, and reminding the reader of this practice where appropriate.

2. Expected Linear Convergence. We develop the local convergence results for GROUSE in this section. The analysis is surprisingly technical for such a simple method, so we break the exposition into relatively short subsections. A brief summary of our proof strategy is as follows. Subsection 2.1 obtains a lower-bounding expression for the improvement in the measure \(\epsilon_t\) (1.12) made over a single step. Subsection 2.2...
shows that the Frobenius-norm difference between $U_t$ and $\bar{U}$ can be bounded above and below by multiples of $\epsilon_t$. Subsection 2.3 examines some consequence of partial observation — the fact that only a subset $\Omega_t$ of elements of $v_t$ is revealed at each iteration. This subsection introduces an assumed lower bound $q$ on the cardinality of $\Omega_t$; subsequent analysis makes use of assumptions on the size of $q$ to guarantee linear convergence. Subsection 2.4 examines a particular term that appeared in the lower-bounding expression for $\epsilon_t - \epsilon_{t+1}$ obtained earlier in Subsection 2.1, deriving an upper bound for this quantity in terms of $\epsilon_t$. This bound is used in Subsection 2.5 to restate the results of Subsection 2.1. Subsection 2.6 defines the concept of coherence used in this paper, and uses a measure concentration result to show that the eigenvalue check (1.3) is satisfied on most iterations. Subsection 2.7 proves a high-probability bound for the ratio $\|r_t\|/\|p_t\|$, which is the dominant term in the error improvement $\epsilon_t - \epsilon_{t+1}$. This bound is given in terms of the angle $\theta_t$ that is the angle between $R(U_t)$ and $S$ that is revealed by the (full) random observation vector $v_t$. Subsection 2.8 shows that the expected value of $\sin^2 \theta_t$ is $\epsilon_t/d$. Finally, Subsection 2.9 proves the expected linear convergence rate.

### 2.1. A Bound for $\epsilon_t - \epsilon_{t+1}$

To obtain an expression for $\epsilon_{t+1} - \epsilon_t$, where $\epsilon_t$ is the quantity defined in (1.12), we start by defining the $d \times d$ orthogonal matrix $W_t$ as

$$W_t := \begin{bmatrix} w_t / \|w_t\| & Z_t \end{bmatrix},$$

where $Z_t$ is a $d \times (d - 1)$ matrix with orthonormal columns whose columns span $N(w_t^T)$. It is clear that the first column of $U_t W_t$ is

$$U_t w_t / \|w_t\| = p_t / \|p_t\|.$$

Let us now write the update formula (1.2) as follows

$$U_{t+1} := U_t + \begin{bmatrix} y_t / \|y_t\| - p_t / \|p_t\| \end{bmatrix} \frac{w_t^T}{\|w_t\|} W_t,$$

where $y_t / \|y_t\| := \cos(\sigma_t \eta_t) p_t / \|p_t\| + \sin(\sigma_t \eta_t) r_t / \|r_t\|$.

By using a trigonometric identity together with (1.5), we can see that the right-hand side of (2.3) has unit norm. From (2.2), we have

$$U_{t+1} W_t = U_t W_t + \begin{bmatrix} y_t / \|y_t\| - p_t / \|p_t\| \end{bmatrix} \frac{w_t^T}{\|w_t\|} W_t$$

$$= U_t W_t + \begin{bmatrix} y_t / \|y_t\| - p_t / \|p_t\| \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & \ldots & 0 \end{bmatrix},$$

where $y_t$ is defined in (2.3). Thus, the update has the effect of replacing the first column $p_t / \|p_t\|$ of $U_t W_t$ by $y_t / \|y_t\|$, and leaving the other columns unchanged. Recalling that the Frobenius norm is invariant under orthogonal transformations, using (1.12)
and (2.3), and dropping the subscript $t$ freely on scalars and vectors, we obtain

$$
\epsilon_t - \epsilon_{t+1} = \|U^T U_{t+1}\|_F^2 - \|U^T U_t\|_F^2
$$

$$
= \|\cos(\sigma \eta) \bar{U}^T p\|_2^2 + \sin(\sigma \eta) \bar{U}^T r \|_2^2 - \|\bar{U}^T p\|_2^2
$$

$$
= (\cos^2(\sigma \eta) - 1) \|\bar{U}^T p\|_2^2 + 2 \cos(\sigma \eta) \sin(\sigma \eta) \frac{(\bar{U}^T p)^T (\bar{U}^T r)}{\|p\| \|r\|} + \sin^2(\sigma \eta) \|\bar{U}^T r\|_2^2
$$

$$
= \sin^2(\sigma \eta) \left( \frac{\|\bar{U}^T r\|_2^2 - \|\bar{U}^T p\|_2^2}{\|p\|} \right) + \sin(2\sigma \eta) \frac{(\bar{U}^T p)^T (\bar{U}^T r)}{\|p\| \|r\|}
$$

$$
\geq -\sin^2(\sigma \eta) + \sin(2\sigma \eta) \frac{(\bar{U}^T p)^T (\bar{U}^T r)}{\|p\| \|r\|},
$$

(2.4)

where the final inequality follows from $\|\bar{U}^T p\| \leq \|p\|$ (since the columns of $\bar{U}$ are orthonormal) and $\|\bar{U}^T r\|^2 / \|r\|^2 \geq 0$. Choosing $\eta_t$ so that (1.10) is satisfied, we have from $\sin^3(\sigma \eta) \in [0, 1]$ and for any scalar $\beta$ that

$$
\beta \sqrt{1 - \sin^2(\sigma \eta)} \geq \beta - |\beta| \sin^2(\sigma \eta),
$$

and thus by substituting (1.10),

$$
\sin(2\sigma \eta) \beta = 2 \sin(\sigma \eta) \beta \sqrt{1 - \sin^2(\sigma \eta)}
$$

$$
\geq 2 \sin(\sigma \eta) \beta - 2 \sin^3(\sigma \eta) |\beta| = 2\alpha \frac{\|r\|}{\|p\|} |\beta| - 2\alpha^3 \frac{\|r\|^3}{\|w\|^3} |\beta|.
$$

By substituting into (2.4), we obtain

$$
\epsilon_t - \epsilon_{t+1} \geq -\alpha \frac{2 \|r\|^2}{\|p\|} + 2 \alpha \frac{\|r\|}{\|p\|} \frac{(\bar{U}^T p)^T (\bar{U}^T r)}{\|p\| \|r\|} - 2\alpha \frac{\|r\|^2}{\|p\|} \frac{|(\bar{U}^T p)^T (\bar{U}^T r)|}{\|p\|^2}
$$

(2.5)

We will return to formula (2.5) in Section 2.4. To preview: we will show that

$$
(\bar{U}^T p)^T (\bar{U}^T r) \approx \|r\|^2,
$$

(2.6)

and that the final term on the right-hand side is higher-order. Thus, we can deduce that the right-hand side of (2.5) is approximately

$$
\alpha(2 - \alpha) \frac{\|r\|^2}{\|p\|^2},
$$

and hence that the approximate maximal improvement $\epsilon_t - \epsilon_{t+1}$ is obtained by setting $\alpha = 1$, as claimed earlier.

### 2.2. Relating $U_t$ to $\bar{U}$

We state here a fundamental result about the relationship between $U_t$, $\bar{U}$, and the quantity $\epsilon_t$ defined in (1.12). After an orthogonal transformation, the squared-Frobenius-norm difference between $U_t$ and $\bar{U}$ is of the same order as $\epsilon_t$.

Recalling the definition (1.11) of the principal angles $\phi_i(U_t, \bar{U})$ between the subspaces spanned by the columns of $U_t$ and the columns of $\bar{U}$, we define

$$
\Sigma_t := \text{diag} \left( \sin \phi_i(\bar{U}, U_t) \right), \quad \Gamma_t := \text{diag} \left( \cos \phi_i(\bar{U}, U_t) \right).
$$

(2.7)
Recalling (1.12) and using the definitions (1.11) and (2.7), we have

\[ \|\Sigma\|_F^2 = \sum_{i=1}^d \sin^2 \phi_i(\bar{U}, U_t) = \epsilon_t, \]

(2.8a)

\[ \|\Gamma\|_F^2 = \sum_{i=1}^d \sigma_i(\bar{U}^T U_t) = \sum_{i=1}^d \cos^2 \phi_i(\bar{U}, U_t) = d - \epsilon_t, \]

(2.8b)

\[ \|\bar{U}\bar{U}^T - U_t U_t^T\|_F^2 = 2d - 2\|\bar{U}^T U_t\|_F^2 = 2\epsilon_t. \]

(2.8c)

We have the following lemma.

**Lemma 2.1.** Let \( \epsilon_t \) be as in (1.12) and suppose \( n \geq 2d \). Then there is an orthogonal matrix \( V_t \in \mathbb{R}^{d \times d} \) such that \( \epsilon_t \leq \|\bar{U}V_t - U_t\|_F^2 \leq 2\epsilon_t \), and thus \( \|\bar{U}^T U_t - V_t\|_F^2 \leq 2\epsilon_t \).

**Proof.** The proof uses [17, Theorem 5.2]. There are unitary matrices \( Q_t, \bar{Y}, \) and \( Y_t \) such that

\[ Q_t \bar{U} \bar{Y} := \begin{pmatrix} I & \Gamma_t \\ 0 & -\Sigma_t \end{pmatrix}, \quad Q_t U_t Y_t := \begin{pmatrix} \Gamma_t \\ \Sigma_t \end{pmatrix} \]

(2.9)

where \( \Gamma_t \) and \( \Sigma_t \) are as defined in (2.7). Defining the orthogonal matrix \( V_t := YY_t^T \) we have that

\[ \bar{U}V_t = Q_t^T \begin{pmatrix} I & \Gamma_t \\ 0 & -\Sigma_t \end{pmatrix} \bar{Y}^T \bar{Y}_t^T \]

\[ = Q_t^T \begin{pmatrix} I \\ 0 \end{pmatrix} Y_t^T \]

\[ = Q_t^T \begin{pmatrix} \Gamma_t \\ \Sigma_t \end{pmatrix} Y_t^T + Q_t^T \begin{pmatrix} I - \Gamma_t \\ -\Sigma_t \end{pmatrix} Y_t^T \]

\[ = U_t + Q_t^T \begin{pmatrix} I - \Gamma_t \\ -\Sigma_t \end{pmatrix} Y_t^T. \]

Therefore, using the abbreviated notation \( \phi_i := \phi_i(\bar{U}, U_t) \), together with orthogonality of \( Q_t \) and \( Y_t \), we have

\[ \|\bar{U}V_t - U_t\|_F^2 = \|I - \Gamma_t\|_F^2 + \|\Sigma_t\|_F^2 = \sum_{i=1}^d [(1 - \cos \phi_i)^2 + \sin^2 \phi_i]. \]

By dropping the cosine part of each summation term, we obtain from (1.12) that \( \|\bar{U}V_t - U_t\|_F^2 \geq \sum_{i=1}^d \sin^2 \phi_i = \epsilon_t \), proving the lower bound. For the upper bound, we
have

\[ \|U_t^T \bar{U} - V_t^T\|^2_F = \sum_{i=1}^d [(1 - \cos \phi_i)^2 + \sin^2 \phi_i] \]

\[ = \sum_{i=1}^d [2 - 2 \cos \phi_i] \leq \sum_{i=1}^d [2 - 2 \cos^2 \phi_i] = 2 \sum_{i=1}^d \sin^2 \phi_i = 2 \epsilon_t, \]

as required. The final claim is an immediate consequence of this upper bound. \[ \square \]

2.3. Consequences of Sampling. In this subsection we investigate some of the issues raised by observing the subspace vector \( v_t \) only on a sample set \( \Omega \subset \{1, 2, \ldots, n\} \), seeing how some of the identities and bounds of Sections 2.1 and 2.2 are affected. We state a lower bound on the cardinality of \( \Omega \) and an upper bound on \( \epsilon_t \) that give sufficient conditions for these looser bounds to hold. These bounds are vital to the analysis of later subsections.

We start with a simple result about the relationship between \( \bar{U} \Omega_t \) and \( U_t \Omega_t \), based on Lemma 2.1.

**Lemma 2.2.** Let \( V_t \) be the matrix from Lemma 2.1. Then \( \|\bar{U} \Omega_t - U_t \Omega_t V_t^T\|^2_F = \|\bar{U} \Omega_t V_t - [U_t] \Omega_t V_t^T\|^2_F \leq 2 \epsilon_t. \)

**Proof.** We have

\[ \|\bar{U} \Omega_t V_t - [U_t] \Omega_t\|^2 \leq \|\bar{U} V_t - U_t\|^2_F \leq 2 \epsilon_t, \]

where the last inequality follows from Lemma 2.1. \( \square \)

We now introduce some simplified notation for important quantities in our analysis, and state the representations of the key vectors \( w_t, p_t, w_t, \) and \( v_t \) in terms of this notation. As in other parts of the paper, we drop the subscript \( t \) freely on vector quantities.

\[ B := \bar{U} \Omega_t, \]
\[ C := [U_t] \Omega_t, \]
\[ P_{N(C^T)} = (I - C(C^T C)^{-1} C^T), \]
\[ P_{N(B^T)} = (I - B(B^T B)^{-1} B^T), \]
\[ [v_t] \Omega_t = Bs, \]
\[ w = (C^T C)^{-1} C^T Bs, \]
\[ p = U_t w = U_t (C^T C)^{-1} C^T Bs, \]
\[ [p_t] \Omega_t = P_{R(C)} Bs, \]
\[ [r_t] \Omega_t = Bs - [p_t] \Omega_t = (I - C(C^T C)^{-1} C^T) Bs = P_{N(C^T)} Bs. \]

The notation \( B \) and \( C \) from (2.10a) and (2.10b) is used for simplicity in this subsection and the next. The reader will note that we have used both \( (B^T B)^{-1} \) and \( (C^T C)^{-1} \) freely. This property requires that our assumption (1.3) holds for \( U_t \). It requires a similar property for \( \bar{U} \Omega_t \), something we simply assume for now, but prove later as a consequence of incoherence; see Theorem 2.6.

Note that we have from (2.10f) and (2.10i) that

\[ P_{N(C^T)} [r_t] \Omega_t = P_{N(C^T)} (Bs_t - Cw_t) = P_{N(C^T)} Bs_t. \]
For the remainder of the paper, we make the following assumptions on the size of the sample set $\Omega_t$ and the size of $\epsilon_t$:

$$|\Omega_t| \geq q,$$  \hspace{1cm} (2.12)

$$\epsilon_t \leq \frac{1}{128} \frac{q^2}{n^2d}.$$  \hspace{1cm} (2.13)

In later subsections, we will derive conditions on $q$ that facilitate the convergence results. For now, we have the following estimates on vectors of interest.

**Lemma 2.3.** Suppose that (1.3) holds and that (2.12) and (2.13) are satisfied. Then we have

$$\|r_t\| \leq \sqrt{2\epsilon_t}\|s_t\|,$$  \hspace{1cm} (2.14)

$$\|p_t\| \in \left[\frac{3}{4}\|s_t\|, \frac{5}{4}\|s_t\|\right],$$  \hspace{1cm} (2.15)

$$\frac{\|r_t\|^2}{\|p_t\|^2} \leq \frac{32}{9}\epsilon_t.$$  \hspace{1cm} (2.16)

**Proof.** We have from (2.10i), $[r_t]_{\Omega_t^c} = 0$, the fact that $P_{N(C^T)} C = 0$, and Lemma 2.2 that

$$\|r_t\| = \|[r_t]_{\Omega_t}\| = \|P_{N(C^T)} Bs_t\| = \|P_{N(C^T)}(B - CV^T)s_t\| \leq \|B - CV^T\|\|s_t\| \leq \sqrt{2\epsilon_t}\|s_t\|,$$

proving (2.14).

We prove the lower bound in (2.15) (the upper bound is similar). We have from $\|C\| \leq \|U_t\| = 1$, Lemma 2.2 (1.4), (2.12), and (2.13), that

$$\|p_t\| = \|w_t\| = \|(C^T C)^{-1} C^T Bs_t\| = \|(C^T C)^{-1} C^T BV^T s_t\| \geq \|s_t\| - \|(C^T C)^{-1} C^T BV - C\|\|s_t\| \geq \|s_t\| - \|(C^T C)^{-1}\|\|C\|\|BV - C\|\|s_t\|$$

$$\geq \|s_t\| - \frac{2n}{|\Omega_t|} \sqrt{2\epsilon_t}\|s_t\|$$

$$\geq \|s_t\| - \frac{2n}{q} \sqrt{2\epsilon_t}\|s_t\|$$

$$\geq \|s_t\| - \frac{2n}{q} \frac{1}{8\sqrt{d}}\|s_t\|$$

$$\geq \|s_t\| - \frac{1}{4}\|s_t\| = \frac{3}{4}\|s_t\|.$$

The final bound (2.16) follows immediately from the preceding two results.

**2.4. Estimating** $(\bar{U}^T p)^T(\bar{U}^T r)$. We return now to the key quantity $(\bar{U}^T p)^T(\bar{U}^T r)$ that appears in (2.5), with the goal of establishing a precise form of the estimate (2.6). Throughout this section, we assume that the conditions (2.12) and (2.13) are satisfied.
We start by noting from (2.11) that

\[ U^T r = B^T r_1 \Omega = B^T P_{N(CT)} B s_t = B^T P_{N(CT)} r_1 \Omega, \]
\[ U^T p = U^T U_t w_t, \]

and therefore

\[ (U^T r)^T (U^T p) = [r_1]_{\Omega}^T P_{N(CT)} B U^T U_t w. \]  \hspace{1cm} (2.17)

By replacing \( \bar{U}^T U_t \) with \( V + \bar{U}^T U_t - V \) (where \( V = V_t \) is the orthogonal matrix from Lemma 2.1) and manipulating, we obtain

\[
P_{N(CT)} B U^T U_t w = P_{N(CT)} B V w + P_{N(CT)} B (\bar{U}^T U_t - V) w
\]
\[
= P_{N(CT)} B V (C^T C)^{-1} CT B s + P_{N(CT)} (B V - C) V^T (\bar{U}^T U_t - V) w
\]
\[
= P_{N(CT)} (B V - C) (C^T C)^{-1} CT (C + B V - C) V^T s +
\]
\[
P_{N(CT)} (B V - C) V^T (\bar{U}^T U_t - V) w
\]
\[
= P_{N(CT)} (B - CV^T) s + P_{N(CT)} (B - CV^T) z
\]
\[ = [r_1]_{\Omega} + P_{N(CT)} (B - CV^T) z, \]  \hspace{1cm} (2.18)

where the final equality comes from (2.11), and we define

\[ z := V (C^T C)^{-1} CT (B V - C) V^T s + (\bar{U}^T U_t - V) (C^T C)^{-1} CT B s. \]

From (1.3), we have

\[ \|C\| \leq \sqrt{\frac{3|\Omega|}{2n}}. \]

By using this bound, together with (1.4), \( \|B\| \leq \|\bar{U}\| = 1 \), Lemma 2.1, and (2.12), we obtain

\[
\|z\| \leq \|(C^T C)^{-1}\|_2 \|C\|_2 \|B V - C\|_2 \|s\|_2 + \|\bar{U}^T U_t - V\|_2 \|(C^T C)^{-1}\|_2 \|C\|_2 \|B\|_2 \|s\|_2
\]
\[
\leq \frac{2n}{|\Omega|} \sqrt{\frac{3|\Omega|}{2n}} \sqrt{2\epsilon_t} \|s\|_2 + \sqrt{2\epsilon_t} \frac{2n}{|\Omega|} \sqrt{\frac{3|\Omega|}{2n}} \|s\|_2
\]
\[
= 4\sqrt{3} \sqrt{\frac{n}{|\Omega|}} \sqrt{\epsilon_t} \|s\|_2 \leq 4\sqrt{3} \sqrt{\frac{n}{q}} \sqrt{\epsilon_t} \|s\|_2.
\]

By combining this bound with (2.18) and (2.17), we obtain

\[
(U^T r)^T (U^T p) \geq \|r\|^2 - \|[r_1]_{\Omega}^T P_{N(CT)} (B - CV^T) z\|\]
\[
\geq \|r\|^2 - \|r\| \|B - CV^T\| \|z\|
\]
\[
\geq \|r\|^2 - \|r\|\sqrt{2\epsilon_t} 4\sqrt{3} \sqrt{\frac{n}{q}} \sqrt{\epsilon_t} \|s\|_2
\]
\[
\geq \|r\|^2 - 8\sqrt{3} \sqrt{\frac{n}{q}} \epsilon_t^{3/2} \|s\|_2^2, \]  \hspace{1cm} (2.19)
where for the final inequality we used \(2.14\). We apply a similar argument to obtain an upper bound on \((\bar{U}^T r)^T (\bar{U}^T p)\), leading to a bound on the absolute value:

\[
|((\bar{U}^T r)^T (\bar{U}^T p)| \leq \|r\|^2 + 8\sqrt{3} \frac{n}{q} \epsilon_t^{3/2} \|s\|^2. \tag{2.20}
\]

From the bound \(2.14\), we have \(\|s_t\|^2 / \|t_t\|^2 \leq (4/3)^2\), and thus from \(2.19\) we obtain

\[
(\bar{U}^T p)^T (\bar{U}^T r) \geq \|r\|^2 / \|p\|^2 - 8\sqrt{3} \frac{n}{q} \epsilon_t^{3/2} 16 \frac{9}{9} = \|r\|^2 / \|p\|^2 - \frac{128\sqrt{3}}{9} \frac{n}{q} \epsilon_t^{3/2}. \tag{2.21}
\]

Likewise, from \(2.20\), we have

\[
\begin{align*}
\frac{|(\bar{U}^T p)^T (\bar{U}^T r)|}{\|p\|^2} & \leq \frac{\|r\|^2}{\|p\|^2} + \frac{128\sqrt{3}}{9} \frac{n}{q} \epsilon_t^{3/2}.
\end{align*} \tag{2.22}
\]

Using \(2.16\) together with the bound \(2.13\) on \(\epsilon_t\), we obtain from \(2.22\) that

\[
\begin{align*}
\frac{|(\bar{U}^T p)^T (\bar{U}^T r)|}{\|p\|^2} & \leq 32 \frac{9}{9} \epsilon_t + \frac{128\sqrt{3}}{9} \frac{n}{q} 8\sqrt{2} \frac{1}{n} \sqrt{\epsilon_t} \\
& = \frac{32}{9} \epsilon_t + 8\sqrt{6} \frac{9}{9} \sqrt{\frac{q}{n}} \frac{n}{d} \epsilon_t \\
& \leq \frac{64}{9} \epsilon_t,
\end{align*} \tag{2.23}
\]

where the last inequality follows from \(q \leq n\) and \(d \geq 1\).

### 2.5. Bounding \(\epsilon_{t+1}\)

We return now to the inequality \(2.5\), using the bounds from the previous subsection to refine our upper bound on \(\epsilon_{t+1}\). By rearranging \(2.5\) and substituting \(2.21\), \(2.22\), \(2.16\), and \(2.23\), we obtain

\[
\begin{align*}
\epsilon_{t+1} & \leq \epsilon_t + \alpha^2 \frac{\|r\|^2}{\|p\|^2} - 2\alpha \frac{(\bar{U}^T p)^T (\bar{U}^T r)}{\|p\|^2} + 2\alpha^3 \frac{\|r\|^2}{\|p\|^2} \frac{|(\bar{U}^T p)^T (\bar{U}^T r)|}{\|p\|^2} \\
& \leq \epsilon_t + \alpha^2 \frac{\|r\|^2}{\|p\|^2} - 2\alpha \frac{\|r\|^2}{\|p\|^2} + \frac{256\sqrt{3}}{9} \frac{n}{q} \epsilon_t^{3/2} + 2\alpha^3 \left( \frac{32}{9} \epsilon_t \right) \left( \frac{64}{9} \epsilon_t \right).
\end{align*}
\]

By bounding \(\epsilon_t^{1/2}\) using \(2.13\) in the last term, we obtain

\[
\begin{align*}
\epsilon_{t+1} & \leq \epsilon_t - (2 - \alpha) \frac{\|r\|^2}{\|p\|^2} + \frac{256\sqrt{3}}{9} \alpha \frac{n}{q} \epsilon_t^{3/2} + \alpha^3 \frac{64}{9\sqrt{2}} \frac{q}{n} \sqrt{\epsilon_t} \\
& \leq \epsilon_t - (2 - \alpha) \frac{\|r\|^2}{\|p\|^2} + \left( \frac{256\sqrt{3}}{9} \alpha + 64 \alpha^3 \right) \sqrt{\frac{n}{q}} \epsilon_t^{3/2},
\end{align*}
\]

where we used \(q \leq n\) and \(d \geq 1\) in the second inequality. It is evident from this expression that \(\alpha_t \equiv 1\) is a good choice for the steplength “fudge factor” in \(1.10\). By fixing \(\alpha_t = 1\) and simplifying the numerical constants in the expression above, we obtain

\[
\epsilon_{t+1} \leq \epsilon_t - \frac{\|r\|^2}{\|p\|^2} + 55 \frac{\sqrt{n}}{q} \epsilon_t^{3/2}. \tag{2.24}
\]

We proceed in Subsection \(2.7\) to develop a high-probability lower bound on \(\|r\|^2 / \|p\|^2\), showing that this term is usually at least a small positive multiple of \(\epsilon_t\). Before doing this, however, it is necessary to discuss the incoherence assumptions and their consequences.
2.6. Incoherence and its Consequences. It is essential to our convergence results that the subspace \( S \) to be identified is incoherent with the coordinate directions, that is, the projection of each coordinate unit vector onto \( S \) should not be too long. This assumption is needed to ensure that the partially sampled observation vectors have sufficient expected information content. We make these concepts precise in this subsection.

**Definition 2.4.** Given a matrix \( U \) of dimension \( n \times d \) with orthonormal columns, defining the subspace \( T := R(U) \), the coherence of \( T \) is

\[
\mu(T) := \frac{n}{d} \max_{i=1,2,\ldots,n} \|P_T e_i\|_2^2,
\]

where \( e_i \) is the \( i \)th unit vector in \( \mathbb{R}^n \). Note that \( 1 \leq \mu(T) \leq n/d \). Since \( P_T = UU^T \), we have (with a slight change of notation)

\[
\mu(U) = \frac{n}{d} \max_{i=1,2,\ldots,n} \|U_i\|_2^2,
\]

where \( U_i \) denotes the \( i \)th row of \( U \). As a special case of this definition, we have for a vector \( x \in \mathbb{R}^n \) that

\[
\mu(x) = n \frac{\|x\|_\infty^2}{\|x\|_2^2}.
\]

We have the following result that relates the coherence of \( R(U_t) \) to that of \( R(\bar{U}) \), for small values of \( \epsilon \).

**Lemma 2.5.** Suppose that \( |\Omega_t| \geq q \), as in (2.12) and that

\[
\epsilon_t \leq \frac{d}{16n} \mu(\bar{U}). \tag{2.25}
\]

Then

\[
\mu(U_t) \leq \mu(\bar{U}) + 4\sqrt{\frac{n}{d}} \epsilon_t^{1/2} \mu(\bar{U})^{1/2} \leq 2 \mu(\bar{U}).
\]

**Proof.** We have by Lemma 2.1 that

\[
\|U_t\|_2 \leq \|\bar{U}_i\|_2 + \|\bar{U}_i - U_t\|_2 \leq \|\bar{U}_i\|_2 + \sqrt{2\epsilon_i}, \quad i = 1, 2, \ldots, d.
\]

By squaring both sides of this inequality and multiplying by \( n/d \), we obtain

\[
\frac{n}{d} \|U_t\|_2^2 \leq \frac{n}{d} \|\bar{U}_i\|_2^2 + \frac{2^{3/2}}{d} \epsilon_t^{1/2} \mu(\bar{U})^{1/2} + \frac{2n}{d} \epsilon_t.
\]

By taking the maxima of both sides over \( i = 1, 2, \ldots, d \), we have from Definition 2.4 that

\[
\mu(U_t) \leq \mu(\bar{U}) + 2^{3/2} \sqrt{\frac{n}{d}} \epsilon_t^{1/2} \mu(\bar{U})^{1/2} + 2 \frac{n}{d} \epsilon_t.
\]

By substituting the bound (2.25) into this expression, we obtain

\[
\mu(U_t) \leq \mu(\bar{U}) + 2^{3/2} \sqrt{\frac{n}{d}} \epsilon_t^{1/2} \mu(\bar{U})^{1/2} + 2 \frac{n}{d} \frac{d}{16n} \mu(\bar{U}) \leq 2 \mu(\bar{U}),
\]
as required. □

We use coherence to analyze the key condition \([1.3]\) that is used in the algorithm to check acceptability of the sample \(\Omega_t\). We show in the following result that the singular values of \(U_\Omega^T U_\Omega\) are all approximately \(\frac{|\Omega|}{\sqrt{n}}\), under an assumption that relates the size of \(\Omega_t\) to the coherence of \(U\). The proof of this result appears in Appendix A.

**Theorem 2.6.** Given an \(n \times d\) matrix \(U\) with orthonormal columns and a parameter \(\delta > 0\), let \(\Omega \subset \{1, 2, \ldots, n\}\) be chosen uniformly with replacement at random such that

\[
|\Omega| > \frac{8}{3} d \mu(U) \log \left( \frac{2d}{\delta} \right).
\]

Then with probability at least \(1 - \delta\), the eigenvalues of \(U_\Omega^T U_\Omega\) lie in an interval

\[
\lambda_i \left( U_\Omega^T U_\Omega \right) \in \left[ \frac{|\Omega|}{n} (1 - \gamma), \frac{|\Omega|}{n} (1 + \gamma) \right], \quad i = 1, 2, \ldots, d,
\]

where

\[
\gamma := \sqrt{\frac{8 d \mu(U)}{3|\Omega|} \log \left( \frac{2d}{\delta} \right)}.
\]  \hspace{1cm} (2.26)

We conclude this subsection with the following result, which quantifies the probability that the condition \([1.3]\) is satisfied. We provide a specific choice for the lower bound \(q\) on sample size that is excessive for current purposes, but useful in later subsections.

**Corollary 2.7.** Suppose that \(\epsilon_t\) satisfies the bounds \([2.13]\) and \([2.25]\). Then condition \([1.3]\) is satisfied with probability at least \(1 - \delta\) if \(|\Omega_t| \geq q\) and \(q\) satisfies

\[
\delta \geq 2d \exp \left( -\frac{3q}{64d \mu(U)} \right).
\]  \hspace{1cm} (2.27)

In particular, \([2.27]\) is satisfied provided that the following conditions hold:

\[
\delta = .1, \quad q \geq C_1 (\log n)^2 d \mu(U) \log(20d), \quad C_1 \geq \frac{64}{3}.
\]  \hspace{1cm} (2.28)

**Proof.** Note first that \([2.27]\) is equivalent to

\[
\log \left( \frac{2d}{\delta} \right) \leq \frac{3q}{64d \mu(U)}.
\]  \hspace{1cm} (2.29)

Since \([2.25]\) is assumed to hold, we can apply Lemma \(2.5\) to obtain

\[
|\Omega_t| \geq q \geq \frac{64}{3} d \mu(U) \log \left( \frac{2d}{\delta} \right) \geq \frac{32}{3} d \mu(U_t) \log \left( \frac{2d}{\delta} \right),
\]

so that the condition of Theorem \(2.6\) is satisfied, with a factor of 4 to spare. By applying this theorem, we obtain

\[
\gamma^2 = \frac{8d \mu(U_t)}{3|\Omega_t|} \log \left( \frac{2d}{\delta} \right) \leq \frac{16d \mu(U)}{3q} \log \left( \frac{2d}{\delta} \right) \leq \frac{1}{4},
\]  \hspace{1cm} (2.30)
with the final inequality following from (2.27). Thus (1.3) is satisfied with probability at least $1 - \delta$.

We now verify that (2.28) implies (2.27). From the inequality for $q$ in (2.28), and the assumption that $C_1 \geq \frac{64}{3}$, we have

$$q \geq C_1 (\log n)^2 d\mu(U) \log(20d) \geq \frac{64}{3} d\mu(U) \log(20d).$$

We obtain by rearranging this expression that

$$1 \geq 2d \exp\left(-\frac{3q}{64d\mu(U)}\right),$$

so that the second condition in (2.27) holds for the specific values of $\delta$ and $q$. Thus, we have shown that the values of $\delta$ and $q$ in (2.28) satisfy (2.27), so that (1.3) is satisfied with probability at least .9 for these values of $\delta$ and $q$.

2.7. A High-Probability Lower Bound on $\|r_t\|^2/\|p_t\|^2$. Theorem 2.6 can be used to derive a high-probability result for a lower bound on the quantity $\|r_t\|^2/\|p_t\|^2$, which is the key part of the error decrease expression (2.24) and is therefore critical to our analysis.

We have the following result, which is the main result of [4] and is proved there.

**Lemma 2.8.** Let $\delta > 0$ be given, and suppose that $|\Omega_t| > \frac{8}{3} d\mu(U) \log\left(\frac{2}{\delta}\right)$. (2.31)

Then with probability at least $1 - 3\delta$, we have

$$\| [v_t]_{\Omega_t} - [p_t]_{\Omega_t} \|^2 \geq \frac{\| [\Omega_t] (1 - \xi_t) - \frac{d\mu(U)}{n} \| \| v_t - U_t U_t^T v_t \|^2}{\|1 - \gamma_t\|},$$

where we define $x_t := v_t - U_t U_t^T v_t$, set $\gamma_t$ as in (2.26), and define

$$\xi_t := \sqrt{\frac{2\mu(x_t)^2}{|\Omega_t|} \log\left(\frac{1}{\delta}\right)}, \quad \beta_t := \sqrt{2\mu(x_t) \log\left(\frac{1}{\delta}\right)}.$$ (2.33)

We focus now on the factor in parentheses in (2.32), proposing conditions on $\mu(x_t)$ and $q$ under which it can be bounded below. The conditions on $\mu(x_t)$ are meant to be “realistic” in the sense that this quantity is observed to vary like $\log n$ in practice, so the upper bounds are designed to be a (possibly large) multiple of this quantity.

**Lemma 2.9.** Suppose that $\delta = .1$. Suppose that on some iteration $t$, we have that $|\Omega_t| \geq q$, where $q$ and $C_1$ satisfy the bounds (2.28). Suppose that $\epsilon_t$ satisfies the bounds (2.13) and (2.25) for this value of $q$, and that $\mu(x_t)$ satisfies the following two upper bounds

$$\mu(x_t) \leq \log n \left[ \frac{.045}{\log 10} C_1 d\mu(U) \log(20d) \right]^{1/2},$$

$$\mu(x_t) \leq (\log n)^2 \left[ \frac{.05}{8 \log 10} C_1 \log(20d) \right],$$

(2.34a)

(2.34b)
where $x_t = v_t - U_t U_t^T v_t$ as in Lemma 2.8. Then we have

$$|\Omega_t|(1 - \xi_t) - d\mu(U_t) \frac{(1 + \beta_t)^2}{1 - \gamma_t} \geq \frac{q}{2}, \quad (2.35)$$

where $\xi_t$, $\beta_t$, and $\gamma_t$ are as defined in Lemma 2.8.

**Proof.** We show first that $\xi_t \leq .3$, where $\xi_t$ is defined in (2.33). Since $|\Omega_t| \geq q$ and $\delta = .1$, we have

$$\xi_t^2 = \frac{2\mu(x_t)^2}{|\Omega_t|} \log \frac{1}{\delta} \leq \frac{2\mu(x_t)^2}{q} \log 10 \leq \frac{1}{q} \left[2(\log n)^2 (0.05)C_1 \log(20d) d\mu(U) \right] \log 10 \quad \text{by (2.34a)}.$$

$$\xi_t^2 \leq \frac{(0.9)q}{q} = .09,$$

establishing the claim.

We show next that the last term on the left-hand side of (2.35) is bounded by .2q. The first step is to verify that $\gamma_t \leq .5$ for $\gamma_t$ defined in (2.26). When $\delta = .1$ and $q$ and $C_1$ satisfy the bounds (2.28) (as we assume here), we have

$$\gamma_t^2 = \frac{8d\mu(U_t)}{3|\Omega_t|} \log \left(\frac{2d}{\delta}\right) \leq \frac{16d\mu(U)}{3|\Omega_t|} \log(20d) \leq \frac{C_1 d\mu(U)}{4q} \log(20d) \leq \frac{1}{4},$$

where we used Lemma 2.5 in the first inequality and (2.28) for the remaining inequalities.

We obtain next a bound on $(1 + \beta_t)^2$. From the definition of $\beta_t$ and the fact that $\mu(x_t) \geq 1$, we have

$$\beta_t = \sqrt{2\mu(x_t) \log \frac{1}{\delta}} = \sqrt{2\mu(x_t) \log 10} \geq 1,$$

so that

$$(1 + \beta_t)^2 \leq (2\beta_t)^2 \leq 8\mu(x_t) \log 10 \leq (\log n)^2 (0.05)C_1 \log(20d) \quad \text{by (2.34b)}.$$ \hspace{1cm} \text{(2.28)}.$$

By using these last two bounds in conjunction with Lemma 2.5, we obtain

$$d\mu(U_t) \frac{(1 + \beta_t)^2}{1 - \gamma_t} \leq 2d\mu(U) \frac{(0.05)q}{d\mu(U)} \leq \frac{1}{5}q = .2q.$$

The result (2.35) follows by combining this bound with $1 - \xi_t \geq .7$ (proved earlier) and $|\Omega_t| \geq q$ (assumed). ∎
We now derive a high-probability lower bound on $\|r_t\|^2/\|p_t\|^2$.

**Lemma 2.10.** Suppose that $|\Omega_t| \geq q$ for all $t$, where $q$ and $C_1$ satisfy the bounds (2.28). Suppose that $\epsilon_t$ satisfies the bounds (2.13) and (2.25). Suppose that there is a quantity $\delta \in (0, 6)$ such that the bounds (2.34) are satisfied by $x_t = v_t - U_tU_t^Tv_t$ with probability at least $1 - \delta$. Then with probability at least $1 - \delta$, we have that

$$
\frac{\|r_t\|^2}{\|p_t\|^2} \geq \frac{q}{2n} \sin^2 \theta_t,
$$

where $\theta_t$ is the angle between $v_t$ and $R(U_t)$.

**Proof.** Since we assume (2.28), and thus that $\delta = .1$, we have from Corollary 2.1 that (1.3) is satisfied with probability at least $1 - \delta = 1 - .1 = .9$. From Lemma 2.8 we have that (2.32) holds with probability at least $1 - 3\delta = 1 - .3 = .7$. We have assumed further that (2.34) holds with probability $1 - \delta$. Thus, from the union bound, we have under our assumptions that the bounds (1.3), (2.12), and (2.13) all hold with probability at least $1 - \delta$. Since, in particular, the conditions (1.3), (2.12), and (2.13) are satisfied under this scenario, we have from Lemma 2.3 that

$$
\|p_t\| \leq \frac{5}{4} \|s_t\| = \frac{5}{4} \|v_t\|.
$$

By using this bound together with the definitions of $[r_t]_{\Omega_t}$ and $[r_t]_{\Omega_t^c}$ in Algorithm 1 and Lemmas 2.8 and 2.9, we obtain

$$
\frac{\|r_t\|^2}{\|p_t\|^2} \geq \frac{16}{25} \frac{\|r_t\|^2}{\|s_t\|^2} = \frac{16}{25} \frac{\|v_t\|^2 - \|p_t\|^2}{\|v_t\|^2} \geq \frac{16}{25} \frac{q}{2n} \frac{\|v_t - U_tU_t^Tv_t\|^2}{\|v_t\|^2}.
$$

Using orthonormality of the columns of $U_t$ and the definition of $\cos \theta_t$, we obtain

$$
\frac{\|v_t - U_tU_t^Tv_t\|^2}{\|v_t\|^2} = \frac{\|v_t\|^2 - v_t^T(U_tU_t^Tv_t)}{\|v_t\|^2} = 1 - \frac{\|v_t^T(U_tU_t^Tv_t)\|^2}{\|v_t\|^2\|U_tU_t^Tv_t\|^2} = 1 - \cos^2 \theta_t = \sin^2 \theta_t.
$$

We complete the proof by combining the last two expressions. \( \square \)

**2.8. Expectation for the Angle Captured by $v_t$.** Here we obtain an expected value for the quantity $\sin^2 \theta_t$, where $\theta_t$ is the angle between the (full) random sample vector and the subspace $R(U_t)$. Noting that $v_t = \tilde{U}s_t$, where $s_t$ is random, we have

$$
\cos^2 \theta_t = \frac{((\tilde{U}s_t)^T(U_tU_t^T\tilde{U}s_t))^2}{\|s_t\|^2\|U_tU_t^T\tilde{U}s_t\|^2} = \frac{s_t^T\tilde{U}^TU_tU_t^T\tilde{U}s_t}{\|s_t\|^2}.
$$

We start with two elementary technical results.

**Lemma 2.11.** Let $w \in \mathbb{R}^d$ be a random vector whose components $w_i$, $i = 1, 2, \ldots, d$ are independent and identically distributed. Then

$$
E \left( \frac{w_i^2}{\sum_{j=1}^d w_j^2} \right) = \frac{1}{d}.
$$

**Proof.** By the additive property of expectation, we have

$$
1 = E \left( \frac{\sum_{i=1}^d w_i^2}{\sum_{j=1}^d w_j^2} \right) = \sum_{i=1}^d E \left( \frac{w_i^2}{\sum_{j=1}^d w_j^2} \right) = dE \left( \frac{w_i^2}{\sum_{j=1}^d w_j^2} \right), \quad i = 1, 2, \ldots, d.
$$
since each of the \( w_i \) is identically distributed. \( \Box \)

**Lemma 2.12.** Given any matrix \( Q \in \mathbb{R}^{d \times d} \), suppose that \( w \in \mathbb{R}^d \) is a random vector whose components \( w_i, i = 1, 2, \ldots, d \) are all i.i.d. \( \mathcal{N}(0, 1) \). Then

\[
E \left( \frac{w^T Q w}{w^T w} \right) = \frac{1}{d} \text{trace} \, Q.
\]

**Proof.**

\[
E \left( \frac{w^T Q w}{w^T w} \right) = \sum_{i \neq j} E \left( \frac{w_i w_j Q_{ij}}{\|w\|^2} \right) + \sum_{i=1}^{n} E \left( \frac{w_i^2 Q_{ii}}{\|w\|^2} \right)
= \sum_{i=1}^{n} Q_{ii} E \left( \frac{w_i^2}{\|w\|^2} \right) = \frac{1}{d} \text{trace} \, Q,
\]
where the second equality follows from Lemma 2.11 and the fact that \( E \left( \frac{w_i w_j}{\|w\|^2} \right) = 0 \) for \( i \neq j \). \( \Box \)

The main result of this subsection follows.

**Lemma 2.13.** Suppose that \( s_t \in \mathbb{R}^d \) is a random vector whose components are i.i.d. \( \mathcal{N}(0, 1) \). Then

\[
E(\sin^2 \theta_t) = \epsilon_t / d,
\]
where \( \epsilon_t \) is defined in (1.12).

**Proof.** From (2.36), Lemma 2.12, and (1.12) we have

\[
E(\cos^2 \theta_t) = \frac{1}{d} \text{trace}(\bar{U}^T U_t U_t^T \bar{U}) = \frac{1}{d} \|U_t^T \bar{U}\|_F^2 = \frac{1}{d} (d - \epsilon_t) = 1 - \frac{\epsilon_t}{d},
\]
giving the result. \( \Box \)

2.9. Expected Linear Decrease. We now put the pieces of theory derived in the previous subsections together, to demonstrate the expected decrease in \( \epsilon_t \) over a single iteration.

**Theorem 2.14.** Suppose that \( |\Omega_t| \geq q \) for all \( t \), where \( q \) and \( C_1 \) satisfy the bounds (2.28). Suppose that \( \epsilon_t \) satisfies the bounds (2.13) and (2.25). Suppose that there is a quantity \( \delta \in (0, .6) \) such that the bounds (2.34) are satisfied by \( x_t = v_t - U_t U_t^T v_t \) with probability at least \( 1 - \delta \). Suppose that at each iteration, \( s_t \) in (1.1) is a random vector whose components are i.i.d. \( \mathcal{N}(0, 1) \). Then

\[
E[\epsilon_{t+1} | \epsilon_t] \leq \epsilon_t - \left( \frac{32}{3} \right) \left( 0.6 - \delta \right) \frac{q}{nd} \epsilon_t + 55 \sqrt{\frac{n}{q}} \epsilon_t^{3/2}.
\]

**Proof.** Under the given assumptions, we have from (2.24) and Lemma 2.10 that

\[
\epsilon_{t+1} \leq \epsilon_t - \frac{32}{3} \frac{q}{n} \sin^2 \theta_t + 55 \sqrt{\frac{n}{q}} \epsilon_t^{3/2}, \quad \text{with probability at least } 0.6 - \delta,
\]
while

\[
\epsilon_{t+1} \leq \epsilon_t + 55 \sqrt{\frac{n}{q}} \epsilon_t^{3/2}, \quad \text{otherwise}.
\]
We obtain the proof by combining these two results and using Lemma 2.13.

**Corollary 2.15.** Suppose that the conditions of Theorem 2.14 hold and that in addition, \( \epsilon_t \) satisfies the following bound:

\[
\epsilon_t \leq (8 \times 10^{-6})(.6 - \delta)^2 \frac{q^3}{n^3d^2}.
\]

We then have

\[
E[\epsilon_{t+1} | \epsilon_t] \leq \left( 1 - (16)(.6 - \delta) \frac{q}{nd} \right) \epsilon_t.
\]

**Proof.** Given the bound (2.39), we have

\[
55 \sqrt{n} \epsilon_t^{1/2} \leq 55 \sqrt{n} (.0029)(.6 - \delta) \frac{q^{3/2}}{n^{3/2}d} \leq (16)(.6 - \delta) \frac{q}{nd}.
\]

We obtain the result by combining this bound with (2.38).

This result indicates that the rate of decrease in error metric \( \epsilon_t \) is more rapid for higher values of the sampling ratio \( q/n \), and becomes slower as subspace dimension \( d \) increases. The expected decrease in (2.40) is consistent with the factor \( (1 - 1/d) \) that we prove in the next section for the full-data case \( (q = n) \), modulo the factor \( (16)(.6 - \delta) \). The appearance of the latter factor is of course due to the uncertainty caused by sampling.

**3. The Full-Data Case:** \( q = n \). When a random full vector \( v_t \in S \) is available at each iteration of GROUSE (that is, \( \Omega_t \equiv \{1, 2, \ldots, n\} \)), the algorithm and its analysis simplify considerably, as we show in this section. The expected decrease factor in \( \epsilon_t \) at each iteration is asymptotically \( (1 - 1/d) \).

Algorithm 2 is the specialization of Algorithm 1 to the full-data case. Since \( (U_t)^T(U_t)_{\Omega_t} = U_t^T U_t = I \) for all \( i \), the eigenvalue check (1.3) is no longer needed.

**Algorithm 2 GROUSE: Full Data**

Given \( U_0 \) and \( n \times d \) matrix with orthonormal columns, with \( 0 < d < n \);

for \( t = 0, 1, 2, \ldots \) do

Take \( v_t \in S \);

Define \( w_t := \arg \min_w \| U_t w - v_t \|_2^2 = U_t^T v_t \);

Define \( p_t := r_t := v_t - p_t \); \( \sigma_t := \| r_t \| \| p_t \| \);

Choose \( \eta_t > 0 \) and set

\[
U_{t+1} := U_t + \left( \cos(\sigma_t \eta_t) - 1 \right) \frac{p_t}{\| p_t \|} + \sin(\sigma_t \eta_t) \frac{r_t}{\| r_t \|} \| w_t \| \| w_t \|.
\]  

end for

The definitions of certain quantities above are simplified in the full-data case, as we demonstrate here (with the introduction of notation \( A_t := U_t^T \tilde{U} \)):

\[
v_t = \tilde{U} s_t, \quad \text{ (3.2a)}
\]

\[
A_t := \tilde{U}^T \tilde{U}, \quad \text{ (3.2b)}
\]

\[
w_t = U_t^T v_t = U_t^T \tilde{U} s_t = A_t s_t, \quad \text{ (3.2c)}
\]

\[
p_t = U_t w_t, \quad \text{ (3.2d)}
\]

\[
r_t = v_t - U_t w_t = (I - U_t U_t^T) \tilde{U} s_t. \quad \text{ (3.2e)}
\]
We continue to use $\theta_t$ to denote the angle between $S$ and $R(U_t)$ that is exposed by the update vector $v_t$. We have

\[
\cos \theta_t = \frac{\|w_t\|}{\|v_t\|}, \quad \sin \theta_t = \frac{\sqrt{\|v_t\|^2 - \|w_t\|^2}}{\|v_t\|} = \frac{\|r_t\|}{\|v_t\|}. \tag{3.3}
\]

Thus

\[
\sigma_t = \|r_t\|\|p_t\| = \|v_t\|^2 \sin \theta_t \cos \theta_t = \frac{1}{2} \|v_t\|^2 \sin 2\theta_t. \tag{3.4}
\]

By using $A_t$ defined in (3.2b) we have from (1.12) that

\[
\epsilon_t = d - \|A_t\|_F^2 = d - \text{trace}(A_t A_t^T). \tag{3.5}
\]

Our first result provides an exact expression for the relationship between $\epsilon_t + 1$ and $\epsilon_t$. It also motivates an “optimal” choice for $\eta_t$ consistent with the one discussed in Subsection 1.3. The proof of this result is quite technical, involving various trigonometric identities and elementary linear algebra manipulations, so we relegate it to Appendix B.

**Lemma 3.1.** We have for all $t$ that

\[
\epsilon_t - \epsilon_{t+1} = \frac{\sin(\sigma_t \eta_t) \sin(2\theta_t - \sigma_t \eta_t)}{\sin^2 \theta_t} \left(1 - \frac{w_t^T A_t A_t^T w_t}{w_t^T w_t}\right). \tag{3.6}
\]

Moreover, the right-hand side is nonnegative for $\sigma_t \eta_t \in (0, 2\theta_t)$, and zero if $v_t \in R(U_t) = S_t$ or $v_t \perp S_t$ (that is, $\theta_t = 0$ or $\theta_t = \pi/2$).

The expression (3.6) immediately suggests the following choice for $\eta_t$:

\[
\eta_t := \frac{\theta_t}{\sigma_t} = \frac{2\theta_t}{\|v_t\|^2 \sin 2\theta_t}, \tag{3.7}
\]

for which $\sin \sigma_t \eta_t = \|r_t\|/\|v_t\|$. (In the regime $\|r_t\| \ll \|p_t\|$, this choice is similar to (1.8) made for the general case, because of (1.6).) Given (3.7), (3.6) simplifies to

\[
\epsilon_t - \epsilon_{t+1} = \left(1 - \frac{w_t^T A_t A_t^T w_t}{w_t^T w_t}\right). \tag{3.8}
\]

We now proceed with an expected convergence analysis for the choice of $\eta_t$ in (3.7), for which the convergence bound is (3.8).

**Theorem 3.2.** Suppose that in Algorithm 3, $v_t = \bar{U}s_t$, where the components of $s_t$ are chosen i.i.d. from $N(0, 1)$, and that $\eta_t$ chosen as in (3.7) for each $t$. Suppose too that $\epsilon_t \leq \bar{\epsilon}$ for some $\bar{\epsilon} \in (0, 1/3)$. Then

\[
E[\epsilon_{t+1} | \epsilon_t] \leq \left(1 - \frac{1 - 3\epsilon_t}{d}\right) \epsilon_t. \tag{3.9}
\]

**Proof.** From Lemma 2.1 using the $d \times d$ orthogonal matrices $Y_t$ and $\bar{Y}$ defined in (2.9), we have that

\[
A_t = U_t^T \bar{U} = Y_t \Gamma_t \bar{Y}^T,
\]

so that

\[
A_t^T A_t = \bar{Y} \Gamma_t^2 \bar{Y}^T, \quad A_t^T A_t A_t^T = \bar{Y} \Gamma_t^4 \bar{Y}^T.
\]
Thus for the critical term in (3.8), using \( w_t = U_t^T \bar{U} s_t = A_t s_t \), dropping the subscript \( t \) freely, and recalling the definition (2.7) of \( \Gamma_t \), we can write

\[
\frac{w^T A A^T w}{w^T w} = \frac{s^T A A^T s}{s^T s} = \frac{s^T \Gamma^4 \bar{s}}{s^T \bar{s}^2} = \sum_{i=1}^d \frac{s_i^2 \cos^4 \phi_i}{\sum_{i=1}^d s_i^2 \cos^2 \phi_i}, \tag{3.10}
\]

where \( \bar{s} = \bar{Y}^T s \) and \( \phi_i = \phi_i(\bar{U}, U_t) \). Since the components of \( s \) are chosen i.i.d. from \( \mathcal{N}(0,1) \), the components of \( \bar{s} \) are also i.i.d. from \( \mathcal{N}(0,1) \).

We make two useful observations before proceeding. First, from the definition of \( \epsilon_t \) in (1.12), we have

\[
0 \leq \sum_{i=1}^d \frac{s_i^2 \sin^2 \phi_i}{\sum_{i=1}^d s_i^2} \leq \max_{i=1,2,...,d} \sin^2 \phi_i \leq \epsilon_t. \tag{3.11}
\]

Second, for any scalar \( u \) with \( 0 \leq u \leq \bar{\epsilon} \), for any \( \bar{\epsilon} \in [0,1/2) \), we have

\[
1 - \frac{1}{1 - u} = 1 + \frac{u}{1 - u} \leq 1 + 2u.
\]

Returning to (3.10), dropping the indices on the summation terms for clarity, introducing the notation

\[
\psi_t := \frac{\sum s_i^2 \sin^2 \phi_i}{\sum s_i^2},
\]

and noting from (3.11) that \( \psi_t \in [0, \epsilon_t] \), we have

\[
\sum \frac{s_i^2 \cos^4 \phi_i}{\sum s_i^2 \cos^2 \phi_i} \leq \sum \frac{s_i^2 [1 - 2 \sin^2 \phi_i + \sin^4 \phi_i]}{\sum s_i^2 (1 - \sin^2 \phi_i)} \leq \sum \frac{s_i^2 - (2 - \epsilon_t) \sum s_i^2 \sin^2 \phi_i}{\sum s_i^2 - \sum s_i^2 \sin^2 \phi_i} = \frac{1 - (2 - \epsilon_t) \psi_t}{1 - \psi_t} \leq [1 - (2 - \epsilon_t) \psi_t] \left[ 1 + \frac{1}{1 - \epsilon_t} \psi_t \right] = 1 - \frac{2 - \epsilon_t - \frac{1}{1 - \epsilon_t}}{1 - \frac{1}{1 - \epsilon_t}} \psi_t - \frac{2 - \epsilon_t}{1 - \epsilon_t} \psi_t^2 \leq 1 - \frac{2 - \epsilon_t - \frac{1}{1 - \epsilon_t}}{1 - \frac{1}{1 - \epsilon_t}} \psi_t \leq 1 - \frac{2 - \epsilon_t - (1 + 2\epsilon_t)} \psi_t = 1 - (1 - 3\epsilon_t) \psi_t.
\]

We have too from Lemma 2.12 that

\[
E(\psi_t) = \frac{1}{d} \sum_{i=1}^d \sin^2 \phi_i = \frac{\epsilon_t}{d},
\]

where the expectation is taken over \( s_t \). Assembling these results, we have that

\[
E \left( 1 - \frac{w_t^T A_t A_t^T w_t}{w_t^T w_t} \right) = E \left( 1 - \frac{\sum s_i^2 \cos^4 \phi_i}{\sum s_i^2 \cos^2 \phi_i} \right) \geq (1 - 3\epsilon_t) E(\psi_t) = (1 - 3\epsilon_t) \frac{\epsilon_t}{d},
\]

\]
The result follows by taking the conditional expectation of both sides in (3.8), and using the bound just derived. □

This result shows that the sequence \( \{\epsilon_t\} \) converges linearly in expectation with an asymptotic rate of \( (1 - 1/d) \). This rate allows for some interesting observations. First, if \( d = 1 \), it suggests convergence in a single step — as indeed we would expect, as the full vector \( v_t \in S \) would in this case reveal the solution in one step. More generally, we have from the bound

\[
(1 - 1/d)^d \leq \frac{1}{e}
\]

that a decrease factor of about \( e \) can be expected over each set of \( d \) consecutive iterations. By comparison, the same amount of information — \( d \) full vectors randomly drawn from \( S \) — is sufficient to reveal the subspace completely (with probability 1). We could obtain an orthonormal basis by assembling these \( d \) vectors into a \( n \times d \) matrix and performing a singular value decomposition (SVD). (Of course, extension of an SVD-based approach to the case of partial data is not straightforward.)

4. Computational Results. We present some computational results on random problems to illustrate the convergence behavior of GROUSE in both the partial-data and full-data cases.

For the full-data case, we implemented Algorithm 2 in Matlab on a problem for which the \( n \times d \) subspace \( S \) was chosen randomly, as the range space of an \( n \times d \) matrix whose elements are i.i.d. in \( \mathcal{N}(0,1) \). We used a random starting matrix \( U_0 \) whose columns were orthonormalized. Figure 4.1 shows results for \( n = 10000 \) and \( d = 4, d = 6 \). The straight line in this semilog plot (\( t \) vs log \( \epsilon_t \)) represents the predicted asymptotic convergence rate \( (1 - 1/d) \), while the irregular line represents the actual error. There is a close correspondence between these results and the predictions of Theorem 3.2. On early iterations, when \( \epsilon_t \) is large, convergence is slower than the asymptotic rate, as predicted by the presence of the factor \( 1 - 3\epsilon_t \) in the expression (3.9). On later iterations, this factor approaches 1, and the asymptotic rate emerges — the curve of actual errors becomes parallel to the straight line.

For the general case, we chose various values of the dimensions \( n \) and \( d \) and the sampling cardinality \( q \), and ran a number of trials that were constructed in the following manner. The target space \( S \) was defined to be the range space of an \( n \times d \) matrix \( T \) whose entries were chosen i.i.d. from \( \mathcal{N}(0,1) \), and \( \bar{U} \) was obtained by orthonormalizing the columns of \( T \). To obtain a starting matrix \( U_0 \), we added to \( T \)
an $n \times d$ matrix whose elements were chosen i.i.d. from $\mathcal{N}(0, 1/4)$, and orthonormalized the resulting matrix. After running each trial for a large enough number of iterations $N$ to establish an asymptotic convergence rate, we computed the value $X$ to satisfy the following expression:

$$
\epsilon_N = \epsilon_0 \left(1 - \frac{q}{nd}\right)^N,
$$

(4.1)

By comparing with (2.40), we see that $X$ absorbs the factor $(.16)(.6 - \bar{\delta})$ that is independent of $n$, $d$, and $q$, and that arises because of the errors introduced by sampling.

The values of $X$ for various values of $n$, $d$, and $q$ are shown in Figure 4.2. For all $q$ larger than some modest multiple of $d$, $X$ is not too far from 1, showing that the actual convergence rate is not too much different from $(1 - q/(nd))$ and that indeed the analysis is somewhat conservative.

**Appendix A. Proof of Theorem 2.6.**

We start with a key result on matrix concentration.

**Theorem A.1.** (Noncommutative Bernstein Inequality [9, 16].) Let $X_1, \ldots, X_m$
be independent zero-mean square $d \times d$ random matrices. Suppose
\[
\rho_k^2 := \max \{ \|E[X_kX_k^T]\|_2, \|E[X_k^TX_k]\|_2 \}
\]
and $\|X_k\|_2 \leq M$ almost surely for all $k$. Then for any $\tau > 0$,
\[
P\left( \sum_{k=1}^m X_k \geq \tau \right) \leq 2d \exp \left( -\frac{\tau^2/2}{\sum_{k=1}^m \rho_k^2 + M/3} \right).
\]

We proceed with the proof of Theorem 2.6.

Proof. We start by defining the notation
\[
u_k := U_{\Omega(k)}^T \in \mathbb{R}^d,
\]
that is, $u_k$ is the transpose of the row of the row of $U$ that corresponds to the $k$th element of $\Omega$. We thus define
\[
X_k := u_ku_k^T - \frac{1}{n}I_d,
\]
where $I_d$ is the $d \times d$ identity matrix. Because of orthonormality of the columns of $U$, this random variable has zero mean.

To apply Theorem A.1, we must compute the values of $\rho_k$ and $M$ that correspond to this definition of $X_k$. Since $\Omega(k)$ is chosen uniformly with replacement, the $X_k$ are distributed identically for all $k$, and $\rho_k$ is independent of $k$ (and can thus be denoted by $\rho$).

Using the fact that
\[
\|A - B\|_2 \leq \max \{ \|A\|_2, \|B\|_2 \}
\]
for positive semidefinite matrices $A$ and $B$, (A.1) and recalling that $\|u_k\|^2 = \|U_{\Omega(k)}\|^2 \leq d\mu(U)/n$, we have
\[
\left\| u_ku_k^T - \frac{1}{n}I_d \right\|_2 \leq \max \left\{ \frac{d\mu(U)}{n}, \frac{1}{n} \right\}.
\]
Thus we can define $M := d\mu(U)/n$. For $\rho$, we note by symmetry of $X_k$ that
\[
\rho^2 = \|E[X_k^2]\|_2 = \left\| \mathbb{E} \left[ u_ku_k^T - \frac{2}{n}u_ku_k^T + \frac{1}{n^2}I_d \right] \right\|_2
\]
\[
= \left\| \mathbb{E} \left[ u_k(u_k^Tu_k)^T \right] - \frac{1}{n^2}I_d \right\|_2,
\]
where the last step follows from linearity of expectation, and $E(u_ku_k^T) = (1/n)I_d$.

For the next step, we define $S$ to be the $n \times n$ diagonal matrix with diagonal elements $\|u_i\|^2$, $i = 1, 2, \ldots, n$. We thus have
\[
\left\| \mathbb{E}[u_k^Tu_k] \right\|_2 = \left\| \frac{1}{n}U^TSU \right\|_2 \leq \frac{1}{n} \|U\|^2_2S_2 = \frac{1}{n} \frac{d\mu(U)}{n} = \frac{d\mu(U)}{n^2}.
\]
Using (A.1), we have from (A.2) that
\[
\rho^2 \leq \max \left( \left\| \mathbb{E} \left[ u_ku_k^Tu_k \right] \right\|_2, \frac{1}{n^2} \right) \leq \max \left( \frac{d\mu(U)}{n^2}, \frac{1}{n^2} \right) = \frac{d\mu(U)}{n^2}.
\]
since $d\mu(U) \geq d \geq 1$.

We now apply Theorem A.1. First, we restrict $\tau$ to be such that $M\tau \leq |\Omega|\rho^2$ to simplify the denominator of the exponent. We obtain
\[
2d \exp \left( -\frac{\tau^2}{2} \left( \frac{1}{|\Omega|} + \frac{M\tau}{3} n^2 \right) \right) \leq 2d \exp \left( -\frac{\tau^2}{2} \frac{|\Omega| d\mu(U)}{n^2} \right),
\]
and thus
\[
P \left[ \left\| \sum_{k \in \Omega} \left( u_k u_k^T - \frac{1}{n} I_d \right) \right\| > \tau \right] \leq 2d \exp \left( -\frac{3n^2 \tau^2}{8|\Omega| d\mu(U)} \right).
\]
Now take $\tau = \gamma |\Omega| / n$ with $\gamma$ defined in the statement of the lemma. Since $\gamma < 1$ by assumption, $M\tau \leq |\Omega|\rho^2$ holds and we have
\[
P \left[ \left\| \sum_{k \in \Omega} \left( u_k u_k^T - \frac{1}{n} I_d \right) \right\| \leq \frac{|\Omega|}{n} \gamma \right] \geq 1 - \delta.
\]
We have, by symmetry of $\sum_{k \in \Omega} u_k u_k^T$ and the fact that
\[
\lambda_i \left( \sum_{k \in \Omega} u_k u_k^T - \frac{|\Omega|}{n} I \right) = \lambda_i \left( \sum_{k \in \Omega} u_k u_k^T \right) - \frac{|\Omega|}{n},
\]
that
\[
\left\| \sum_{k \in \Omega} \left( u_k u_k^T - \frac{1}{n} I_d \right) \right\|_2 = \left\| \left( \sum_{k \in \Omega} u_k u_k^T \right) - \frac{|\Omega|}{n} I_d \right\|_2
\]
\[
= \max_{i=1,2,\ldots,n} \left| \lambda_i \left( \sum_{k \in \Omega} u_k u_k^T \right) - \frac{|\Omega|}{n} \right|.
\]
From (A.3), we have with probability $1 - \delta$ that
\[
\lambda_i \left( \sum_{k \in \Omega} u_k u_k^T \right) \in \left[ (1 - \gamma) \frac{|\Omega|}{n}, (1 + \gamma) \frac{|\Omega|}{n} \right] \text{ for all } i = 1, 2, \ldots, n,
\]
completing the proof.

**Appendix B. Proof of Lemma 3.1.**

We drop the subscript “$t$” throughout the proof and use $A_+$ in place of $A_{t+1}$. From (3.1), and using the definitions (3.2), we have
\[
A_+^T = \bar{U}^T U_+
\]
\[
= \bar{U}^T U + \left\{ (\cos(\sigma \eta) - 1) \frac{\bar{U}^T U U^T \bar{U} \bar{s}}{||w||} + \sin(\sigma \eta) \frac{(I - \bar{U}^T U U^T \bar{U}) \bar{s}}{||s||} \right\} \bar{s}^T \bar{U}^T U
\]
\[
= \left\{ I + (\cos(\sigma \eta) - 1) \frac{A^T A s s^T}{||w||^2} + \sin(\sigma \eta) \frac{(I - A^T A) s s^T}{||s|| ||w||} \right\} A^T = H A^T,
\]
where the matrix $H$ is defined in an obvious way. Thus
\[
\| A_+ \|^2_F = \text{trace}(A_+ A_+^T) = \text{trace}(A H^T H A^T).
\]
Focusing initially on $H^T H$ we obtain

\[
H^T H = I + (\cos(\sigma\eta) - 1)^2 \frac{ss^T A^T AA^T Ass^T}{\|w\|^4}
\]
\[
+ (\cos(\sigma\eta) - 1) \frac{ss^T A^T A + AT Ass^T}{\|w\|^2}
\]
\[
+ \sin(\sigma\eta) \frac{2ss^T - ss^T AT A - AT Ass^T}{\|r\|\|w\|}
\]
\[
+ 2\sin(\sigma\eta)(\cos(\sigma\eta) - 1) \frac{ss^T AT Ass^T - ss^T AT AA^T Ass^T}{\|r\|\|w\|^3}
\]
\[
+ \sin^2(\sigma\eta) \frac{s(s^T s - 2s^T AT As + s^T AT AA^T As)s^T}{\|r\|^2\|w\|^2}.
\]

It follows immediately that

\[
A_+ A^T_+ = AA^T + (\cos(\sigma\eta) - 1)^2 \frac{Ass^T A^T AA^T Ass^T AT}{\|w\|^4}
\]
\[
+ (\cos(\sigma\eta) - 1) \frac{Ass^T A^T AA^T + AA^T Ass^T AT}{\|w\|^2}
\]
\[
+ \sin(\sigma\eta) \frac{2Ass^T AT - Ass^T AT AA^T - AA^T Ass^T AT}{\|r\|\|w\|}
\]
\[
+ 2\sin(\sigma\eta)(\cos(\sigma\eta) - 1) \frac{Ass^T AT Ass^T AT - Ass^T AT AA^T Ass^T AT}{\|r\|\|w\|^3}
\]
\[
+ \sin^2(\sigma\eta) \frac{As(s^T s - 2s^T AT As + s^T AT AA^T As)s^T AT}{\|r\|^2\|w\|^2}.
\]

We now use repeatedly the fact that $\text{trace } ab^T = a^T b$ to deduce that

\[
\text{trace}(A_+ A^T_+) = \text{trace}(AA^T) + (\cos(\sigma\eta) - 1)^2 \frac{(s^T AT As)(s^T AT AA^T As)}{\|w\|^4}
\]
\[
+ (\cos(\sigma\eta) - 1) \frac{2s^T AT AA^T As}{\|w\|^2}
\]
\[
+ \sin(\sigma\eta) \frac{2s^T AT As - 2s^T AT AA^T As}{\|r\|\|w\|}
\]
\[
+ 2\sin(\sigma\eta)(\cos(\sigma\eta) - 1) \frac{(s^T AT As)^2 - (s^T AT AA^T As)(s^T AT As)}{\|r\|\|w\|^3}
\]
\[
+ \sin^2(\sigma\eta) \frac{\|s\|^2s^T AT As - 2(s^T AT As)^2 + (s^T AT AA^T As)(s^T AT As)}{\|r\|^2\|w\|^2}.
\]
Now using $w = As$ (and hence $s^T A^T As = \|w\|^2$), we have

$$
\text{trace}(A+A^T) = \text{trace}(AA^T) + (\cos(\eta) - 1)^2 \frac{s^T A^T A A^T As}{\|w\|^2} \\
+ (\cos(\eta) - 1) \frac{2s^T A^T A A^T As}{\|w\|^2} \\
+ 2 \sin(\eta) \frac{\|w\|^2 - s^T A^T A A^T As}{\|r\| \|w\|} \\
+ 2 \sin(\eta) \cos(\eta) - 1 \frac{\|w\|^2 - s^T A^T A A^T As}{\|r\| \|w\|} \\
+ \sin^2(\eta) \frac{\|s\|^2 - 2\|w\|^2 + (s^T A^T A A^T As)}{\|r\|^2}.
$$

For the second and third terms on the right-hand side, we use the identity

$$(\cos(\eta) - 1)^2 + 2(\cos(\eta) - 1) = \cos^2(\eta) - 1 = -\sin^2(\eta \sigma),$$

allowing us to combine these terms with the final $\sin^2(\eta \sigma)$ term. Using also the identity $\|r\|^2 = \|s\|^2 - \|w\|^2$, we obtain for the combination of these three terms that

$$\sin^2(\eta \sigma) \left[ 1 - \frac{\|w\|^2}{\|r\|^2} + s^T A^T A A^T As \left( \frac{1}{\|r\|^2} - \frac{1}{\|w\|^2} \right) \right]$$

$$= \sin^2(\eta \sigma) \left( 1 - \frac{\|w\|^2}{\|r\|^2} \right) \left( 1 - \frac{s^T A^T A A^T As}{\|w\|^2} \right).$$

We can also combine the third and fourth terms in the right-hand side above to yield a combined quantity

$$2 \sin(\eta \sigma) \cos(\eta \sigma) \frac{\|w\|}{\|r\|} \left( 1 - \frac{s^T A^T A A^T As}{\|w\|^2} \right).$$

By substituting these two compressed terms into the expression above, we obtain

$$\text{trace}(A+A^T) = \text{trace}(AA^T) \\
+ \sin(\eta \sigma) \left( 1 - \frac{s^T A^T A A^T As}{\|w\|^2} \right) \left[ \left( 1 - \frac{\|w\|^2}{\|r\|^2} \right) \sin(\eta \sigma) + 2 \cos(\eta \sigma) \frac{\|w\|}{\|r\|} \right].$$

We now use the relations (3.3) to deduce that

$$\frac{\|w\|}{\|r\|} = \frac{\cos \theta}{\sin \theta}, \quad 1 - \frac{\|w\|^2}{\|r\|^2} = -\frac{\cos(2\theta)}{\sin^2 \theta},$$

and thus the increment $\text{trace}(A+A^T) - \text{trace}(AA^T)$ becomes

$$\sin(\eta \sigma) \left( 1 - \frac{s^T A^T A A^T As}{\|w\|^2} \right) \left[ \frac{-\cos(2\theta)}{\sin^2 \theta} - \sin(\eta \sigma) + 2 \cos(\eta \sigma) \frac{\cos \theta}{\sin \theta} \right]$$

$$= \frac{\sin(\eta \sigma) \sin(2\theta - \eta \sigma)}{\sin^2 \theta} \frac{\cos(\eta \sigma) \cos \theta}{\sin \theta} \left( 1 - \frac{s^T A^T A A^T As}{\|w\|^2} \right).$$

The result (3.6) follows by substituting $w = As$ and (3.4).
Nonnegativity of the right-hand side follows from \( \theta_t \geq 0, 2\theta_t - \sigma_t \eta_t \geq 0 \), and
\[
\|A_t^T w_t\| \leq \|U_t^T\|\|v_t\| \leq \|w_t\|.
\]

To prove that the right-hand side of (3.6) is zero when \( v_t \in S \) or \( v_t \perp S \), we take the former case first. Here, there exists \( \hat{s}_t \in \mathbb{R}^d \) such that
\[
v_t = \hat{U} \hat{s}_t = U_t \hat{s}_t.
\]
Thus
\[
w_t = A_t s_t = U_t^T \hat{U} \hat{s}_t = U_t^T U_t \hat{s}_t = \hat{s}_t,
\]
so that \( \|v_t\| = \|w_t\| \) and thus \( \theta_t = 0 \), from (3.3). This implies that the right-hand side of (3.6) is zero. When \( v_t \perp S_t \), we have \( w_t = U_t^T v_t = 0 \) and so \( \theta_t = \pi/2 \) and \( \sigma_t = 0 \), implying again that the right-hand side of (3.6) is zero.
