A NEGATIVE ANSWER TO A QUESTION OF ASCHBACHER

ROBERT A. WILSON

Abstract. We give infinitely many examples to show that, even for simple groups \( G \), it is possible for the lattice of overgroups of a subgroup \( H \) to be the Boolean lattice of rank 2, in such a way that the two maximal overgroups of \( H \) are conjugate in \( G \). This answers negatively a question posed by Aschbacher.

1. The question

In a recent survey article on the subgroup structure of finite groups \cite{1}, in the context of discussing open problems on the possible structures of subgroup lattices of finite groups, Aschbacher poses the following specific question. Let \( G \) be a finite group, \( H \) a subgroup of \( G \), and suppose that \( H \) is contained in exactly two maximal subgroups \( M_1 \) and \( M_2 \) of \( G \), and that \( H \) is maximal in both \( M_1 \) and \( M_2 \). Does it follow that \( M_1 \) and \( M_2 \) are not conjugate in \( G \)? This is Question 8.1 in \cite{1}. For \( G \) a general group, he asserts there is a counterexample, not given in \cite{1}, so he restricts this question to the case \( G \) almost simple, that is \( S \leq G \leq \text{Aut}(S) \) for some simple group \( S \). This is Question 8.2 in \cite{1}.

2. The answer

In fact, the answer is no, even for simple groups \( G \). The smallest example seems to be the simple Mathieu group \( M_{12} \) of order 95040.

**Theorem 1.** Let \( G = M_{12} \), and \( H \cong A_5 \) acting transitively on the 12 points permuted by \( M_{12} \). Then \( H \) lies in exactly two other subgroups of \( G \), both lying in the single conjugacy class of maximal subgroups \( L_2(11) \).

**Proof.** The maximal subgroups of \( G \) are well-known, and are listed in the Atlas of Finite Groups \cite[p. 33]{4}. From this list it follows that the only maximal subgroups of \( G \) that contain \( H \) are conjugates of the transitive subgroup \( M \cong L_2(11) \). The maximal subgroups of \( \text{Aut}(G) \cong M_{12}:2 \) are determined in \cite{10}, where it is shown in particular that the normalizers in \( \text{Aut}(G) \) of \( H \) and \( M \) are \( \text{Aut}(H) \cong S_5 \) and \( \text{Aut}(M) \cong PGL_2(11) \) respectively. Since \( PGL_2(11) \) does not contain \( S_5 \), it follows that there are precisely two conjugates of \( M \) that contain \( H \), and that these conjugates are interchanged by elements of \( \text{Aut}(H) \setminus H \). \( \square \)

Of course, one example answers the specific question, but does not address the context in which the question was asked. One needs to consider rather how many examples there are, or whether the phenomenon just exhibited is relatively common or rare. In fact, the results of \cite{10} can be used to deduce the existence of one more example, that is in the sporadic simple group of Held. The relevant subgroup information, obtained in \cite[10]{3}, is summarised in \cite[p. 104]{4}.

\textit{Date:} First draft 11/04/2018; this version 07/06/2018.
Theorem 2. Let $G = \text{He}$ and $H \cong (A_5 \times A_5).2.2$. Then $H$ is contained in just two other subgroups of $G$, both lying in the single class of maximal subgroups isomorphic to $S_4(4):2$.

Proof. It is shown in [3] (see also [10]) that there is a unique class of $A_5 \times A_5$ in the Held group, and that the normalizer of any $A_5 \times A_5$ in $G$ is a group $H$ of shape $(A_5 \times A_5) \times (A_5 \times A_5)$. It follows that $H$ lies inside a maximal subgroup $M \cong S_4(4):2$. Now in $\text{Aut}(G)$ the normalizers of $H$ and $M$ are $S_5 \wr 2$ and $S_4(4):4$ respectively, but $S_4(4):4$ does not contain $S_5 \wr 2$, so the elements of $\text{Aut}(H) \setminus H$ interchange two $G$-conjugates of $M$ that contain $H$.  

The above examples constitute the extent of general knowledge at the time of the publication of the Atlas.

3. Doubly-deleted doubly-transitive permutation representations

Both the examples given so far occur in sporadic groups $G$. There is also at least one example in which $H$ is sporadic, but $G$ is a classical simple group.

Theorem 3. Let $G = \Omega^{-}_{10}(2)$ and $H \cong M_{12}$. Then $H$ is contained in exactly two other subgroups of $G$, both lying in the single conjugacy class of subgroups isomorphic to $A_{12}$.

Proof. In this case there is a crucial error in [4, p. 147] and one needs to use the corrected list of maximal subgroups of $G$ from [5] or [2]. Note in particular that $\text{Aut}(G) \cong \Omega^{-}_{10}(2):2$ contains maximal subgroups $S_{12}$ and $\text{Aut}(M_{12}) \cong M_{12}:2$. Since $S_{12}$ does not contain $M_{12}:2$, we have essentially the same situation as in the two previous examples. The only maximal subgroups of $G$ that contain $H$ are conjugates of $M \cong A_{12}$, and there are exactly two such conjugates, swapped by elements of $\text{Aut}(H) \setminus H$. 

Analysing this example, it is clear that an important property of $M_{12}$ that is being used here is that it has two distinct 2-transitive representations on 12 points, swapped by the outer automorphism. The smallest simple group with such a property is $L_3(2)$, which has two distinct 2-transitive representations on 7 points. In characteristic 7, therefore, there is a doubly-deleted permutation representation, giving rise to an embedding in $\Omega_5(7)$.

Theorem 4. Let $G = \Omega_5(7)$ and $H \cong L_3(2) \cong L_2(7)$ be a subgroup of $G$, acting irreducibly on the 5-dimensional module. Then $H$ is contained in exactly two other subgroups of $G$, both isomorphic to $A_7$, and lying in the same $G$-conjugacy class.

Proof. Reading off the information about irreducible subgroups of $\Omega_5(7)$ and $SO_5(7)$ from [2, Table 8.23], we see that $G = \Omega_5(7)$ has a single class of irreducible subgroups $H = L_3(2)$, and these subgroups are contained in maximal subgroups $M = A_7$. Correspondingly, in $SO_5(7)$ there are maximal subgroups $L_3(2):2$ and $S_7$. The outer automorphism of $L_3(2)$ therefore swaps two $(G$-conjugate) copies of $A_7$ containing $L_3(2)$.

More generally, for all $n \geq 3$ and all prime powers $q$, the simple group $L_n(q)$ has two inequivalent 2-transitive permutation representations on $d := (q^n - 1)/(q - 1)$ points. Not all of these give rise to examples, however. The case $L_3(3) < A_{13} <
Theorem 5. Let \( p \) be a prime, and suppose that \( p \equiv 15, 23, 39 \mod 56 \). Let \( G \) be the simple group \( \Omega_6^+ (p) \cong PSL_4(p) \). Then \( G \) contains subgroups \( L_3(2) < A_7 \), both normalized by the transpose-inverse automorphism of \( L_4(p) \), to \( L_3(2):2 \) and \( S_7 \) respectively. In particular, every such \( L_3(2) \) lies in exactly two copies of \( A_7 \), and these two copies of \( A_7 \) are \( G \)-conjugate.

**Proof.** Consider a pair of subgroups \( L_3(2) < A_7 \) of \( G \), and adjoin \( \alpha \gamma \), where \( \alpha \) is an inner automorphism of \( \Omega_6^+ (p) \), to extend \( A_7 \) to \( S_7 \). This swaps the two classes of \( L_3(2) \) in \( A_7 \). But we can also adjoin \( \beta \gamma \), where \( \beta \) is another inner automorphism, to normalize \( L_3(2) \) to \( L_3(2):2 \). Hence there is an inner automorphism of the form \( \alpha \gamma \beta \gamma \), that conjugates an \( L_3(2) \) of one class in \( A_7 \), to an \( L_3(2) \) of the other class. The same argument with the roles of \( L_3(2) \) and \( A_7 \) reversed shows that the two copies of \( A_7 \) in which \( L_3(2) \) lies are conjugate in \( \Omega_6^+ (p) \).

As a consequence, we have an infinite series of groups \( PSL_4(p) \), for \( p \) any prime with \( p \equiv 15, 23, 39 \mod 56 \), for which Aschbacher’s question has a negative answer. There is a similar infinite series of groups \( PSU_4(p) \), for \( p \equiv 1 \mod 8 \) and \( p \equiv 3, 5, 6 \mod 7 \), that is \( p \equiv 17, 33, 41 \mod 56 \). This can be read off in a similar way from [2, Table 8.11].

Theorem 6. Let \( p \) be a prime, and suppose that \( p \equiv 17, 33, 41 \mod 56 \). Let \( G \) be the simple groups \( \Omega_5^- (p) \cong PSU_4(p) \). Then \( G \) contains subgroups \( L_3(2) < A_7 \), both normalized by the field automorphism of \( U_4(p) \), to \( L_3(2):2 \) and \( S_7 \) respectively. In particular, every such \( L_3(2) \) lies in exactly two copies of \( A_7 \), and these two copies of \( A_7 \) are conjugate in \( G \).

There is an analogous embedding \( L_2(11) < A_{11} \), which one might think gives similar series of examples in \( \Omega_{10}^+ (p) \) for certain \( p \). However, \( L_2(11) \) is not maximal in \( A_{11} \), so this fails.
5. More special examples

As we have just seen, the embedding $L_3(2) < A_7$ behaves differently in characteristic 7 (the special case) from other characteristics (the generic case). More generally, the embedding $L_n(q) < A_d$, where $d = (q^n - 1)/(q - 1)$, behaves differently in the special case (characteristic dividing $d$), compared to the generic case (characteristic prime to $d$).

The special case is easiest to analyse when $d$ is itself prime. In this case, $n$ is necessarily prime, but $q$ need not be prime. This includes all Mersenne primes except 3, and others such as $(3^3 - 1)/(3 - 1) = 13$ and $(5^3 - 1)/(5 - 1) = 31$, for example. We then have embeddings $L_n(q) < A_d < \Omega_d(d)$. The Singer cycles in $L_n(q)$ are represented as $d$-cycles in $A_d$, and as regular unipotent elements in $\Omega_d(d)$. Now there is a unique class of regular unipotent elements in $SO_m(d)$ for all odd $m$, and these elements have order $d$ provided $m \leq d$. The class splits into two classes in $\Omega_m(d)$, and these classes are rational if $m \equiv \pm 1 \mod 8$, and irrational otherwise.

Since $d$ is prime, the $d$-cycles in $S_d$ split into two irrational classes in $A_d$ (by Sylow’s Theorem). The $d$-cycles are conjugate in $A_d$ to their inverses just when $d \equiv 1 \mod 4$. Since the regular unipotent elements have unipotent centralizer, it follows that they are conjugate in $\Omega_d(d)$ to their inverses if and only if either $d \equiv 1 \mod 4$ or $d - 2 \equiv \pm 1 \mod 8$, that is $d \equiv 1, 3, 5 \mod 8$. Now the Singer cycles in $L_n(q)$ are inverted by the transpose-inverse automorphism, and we want this automorphism to be realised by an element of $SO_{d-2}(d) \setminus \Omega_{d-2}(d)$. This happens if and only if $d \equiv 7 \mod 8$.

**Theorem 7.** If $q$ is a prime power, and $d := (q^n - 1)/(q - 1)$ is prime, with $d \equiv 7 \mod 8$, let $H := PGL_n(q)$, $M = A_d$ and $G = \Omega_d(d)$. Then $H < M < G$, and $H$ and $M$ are unique up to conjugacy in $G$. Hence $H$ and $M$ extend to $H.2$ and $M.2$ in $G.2$, and $H$ is contained in exactly two $G$-conjugates of $M$.

The condition $d \equiv 7 \mod 8$ is satisfied by all Mersenne primes (the case $q = 2$), except 3, but not by all primes of the form $(q^n - 1)/(q - 1)$. The condition can be re-written as a condition on the values of $q$ and $n$ modulo 8.

**Lemma 1.** If $d = (q^n - 1)/(q - 1)$, then the condition $d \equiv 7 \mod 8$ is equivalent to the condition that, either

\begin{itemize}
  \item $q = 2$ and $n > 2$, or
  \item $q \equiv 1 \mod 8$ and $n \equiv 7 \mod 8$, or
  \item $q \equiv 5 \mod 8$ and $n \equiv 3 \mod 8$.
\end{itemize}

Only finitely many primes $d$ of the form $(q^n - 1)/(q - 1)$ are known, but it is conjectured that there are infinitely many, including infinitely many Mersenne primes $2^n - 1$. Currently just 50 Mersenne primes are known, giving rise to examples with $H$ isomorphic to $L_3(2)$, $L_5(2)$, $L_7(2)$, $L_{13}(2)$, \ldots, $L_{77232917}(2)$. Less effort has been expended on finding primes for larger values of $q$, but examples for $q = 5$ and $n \equiv 3 \mod 8$ occur when $n = 3, 11, 3407, 16519, 201359$ and 1888279 (see A004061 in the On-line Encyclopedia of Integer Sequences [9]). I could find no examples with $q = 9$ or $q = 13$, but using GAP [5], one can easily find the examples $n = 7, 47$ and 71 for $q = 17$ and $n \equiv 7 \mod 8$.

One can also search for examples by fixing $n$ rather than $q$. For $n = 3$, examples with $q \equiv 5 \mod 8$ and $d$ prime include $q = 5, 101, 173, 293, 677, 701, 773$. A
A NEGATIVE ANSWER TO A QUESTION OF ASCHBACHER

search with $n = 7$ turns up the examples $q = 17, 73, 89, 353, 1297, 1409, 1489, 1609, 1753, 2609, 2753, 3673, 4049, 4409,$ etc., and similarly for $n = 11$, we can take $q = 53, 229, 389, 709, 1213, 2029, 5581, 5669, 5813, 5861, 7229$. For $n = 19$, there are examples for $q = 181, 277, 389, 509, 797, 1693, 1709$, etc. For $n = 23, q = 113, 257, 857, 1801$; for $n = 31, q = 241$, and so on.

In particular, examples of negative answers to Aschbacher’s question arise in the cases of $L_3(5)$, $L_3(101)$, $L_{11}(5)$, $L_7(17)$, and $L_7(73)$. An extremely large example arises from the embedding of $L_{77232917}(2)$ in $A_d$ and $\Omega_{d-2}(d)$, where $d = 2^{77232917} - 1$ is the largest currently known Mersenne prime.

Note that our analysis shows that the case $L_3(3) < A_{13} < \Omega_{11}(13)$ does not provide an example. This can also been seen from the list of maximal subgroups of $\Omega_{11}(q)$ given in [2, Table 8.75].

6. More generic examples

As we have seen, for all $n \geq 3$ and for all $q$, the simple groups $L_n(q)$ have two inequivalent permutation representations on $d := (q^n - 1)/(q - 1)$ points, and hence we obtain two inequivalent embeddings in $A_d$. In the generic case, when $\ell$ is a prime not dividing $d$, the alternating group $A_d$ embeds irreducibly into $\Omega_{d-2}(\ell)$. However, the conditions on $n, q, \ell$ for this to give rise to a negative answer to Aschbacher’s question, are subtle and complicated, as we already saw for the smallest case, $n = 3, q = 2$.

The next smallest case is $n = 3, q = 3$. To analyse this case, that is, the embedding $L_3(3) < A_{13} < P\Omega^+_2(p)$, we may use the information on maximal subgroups of $\Omega^+_2(p)$ provided in [2] Tables 8.83 and 8.85. It follows from these tables that there are no examples here.

The next smallest case is $n = 4, q = 2$, and the embedding of $L_4(2) \cong A_8$ into $A_{15}$ and thence into orthogonal groups in dimensions 13 and 14. The maximal subgroups of these orthogonal groups have been determined by Anna Schroeder, in her St Andrews PhD thesis [3]. In particular, the embeddings into $\Omega_{13}(3)$ and $\Omega_{13}(5)$ do not give examples. In the dimension 14 case, however, it seems that there is a crucial error at exactly the point that interests us here: maximal subgroups $S_8$ are eliminated from the lists of maximal subgroups of $\Omega^+_2(p)$ by the assertion, in [3, Propn. 6.4.17(iv)], that $S_8 \leq S_{15}$, which is manifestly false for this embedding. Indeed, Propositions 6.4.4 and 6.4.5 in [3] give the true picture, and show that $S_8$ is indeed a maximal subgroup of $SO^+_2(p)$ for suitable congruences of $\varepsilon$ and $p$. In the cases when the outer automorphism group of $\Omega^+_2(p)$ is just $2^2$, the calculations are quite straightforward. These are the cases when $\varepsilon p \equiv 3 \bmod 4$.

Theorem 8. Let $p \equiv 19, 23, 31, 47 \bmod 60$, and let $G = \Omega^+_2(p)$. Let $H \cong A_8$ be a subgroup of $G$ acting irreducibly in the 14-dimensional representation. Then $H$ is contained in exactly two maximal subgroups of $G$, both isomorphic to $A_{15}$, and conjugate to each other in $G$.

Proof. Indeed, it is shown in [3] that for $p \equiv 19, 23, 31, 47 \bmod 60$, there are two conjugacy classes of subgroups $S_{15}$, maximal in $SO^+_2(p)$, and swapped by the diagonal automorphism $\delta$. Moreover, it is shown that the intersection of $S_{15}$ with $\Omega^+_2(p)$ is $A_{15}$. Now the same argument applies to the group $S_8$, acting irreducibly in the 14-dimensional representation. Since for this embedding, $S_8$ does not lie in $S_{15}$, it follows that $S_8$ is maximal in $SO^+_2(p)$ in these cases. \[\square\]
Exactly the same argument applies to the cases $p \equiv 13, 29, 37, 41 \mod 60$ in $\Omega_{14}(p)$. It is possible that analogous examples also exist when $\varepsilon p \equiv 1 \mod 4$, but in this case the outer automorphism group is $D_8$, and there are four classes each of $S_8$ and $S_{15}$, so the situation is more complicated.

7. **Unbounded rank**

Generalizing to the representations of $L_n(2)$ of dimension $d-1$, where $d = 2^n - 1$, we find that for $n$ even these representations extend to embeddings of $L_n(2):2$ in $SO_d(p)$ for all $p$, while for $n$ odd this happens only when the field of order $p$ contains square roots of 2, that is, when $p \equiv \pm 1 \mod 8$.

So, for example, the embeddings $L_5(2) < A_{31} < \Omega^\varepsilon_{30}(p)$ provide examples whenever all of the following conditions are satisfied:

- $\varepsilon p \equiv 3 \mod 4$,
- $p \equiv \pm 1 \mod 8$, and
- $p \equiv 1, 2, 4, 8, 16 \mod 31$.

That is to say, for $\varepsilon = +$ we require $p \equiv 39, 47, 63, 95, 159 \mod 248$, while for $\varepsilon = -$ we require $p \equiv 1, 33, 97, 225, 233 \mod 248$.

For the purpose of demonstrating that examples exist of arbitrarily large rank and/or characteristic, it is sufficient to restrict to the case when $\varepsilon = -$, and further to the case when $p \equiv 1 \mod 4(d-1)$. In this case, the embedding of $L_n(2)$ into $A_d$ and thence into $\Omega^\varepsilon_d(p)$ gives an example of a negative answer to Aschbacher’s question. Of course, there are many other examples.

**Theorem 9.** Let $p$ be a prime, and $\varepsilon = \pm$, such that $\varepsilon p \equiv 3 \mod 4$. Let $n \geq 3$, and suppose that $p$ is a square modulo $d := 2^n - 1$. If $n$ is odd, suppose also that $p \equiv \pm 1 \mod 8$. Let $G = \Omega^\varepsilon_{d-1}(p)$, and $H \cong L_n(2)$ a subgroup of $G$. Then $H$ is contained in exactly two maximal subgroups of $G$, which are isomorphic to $A_d$ and conjugate to each other.

**Proof.** The above conditions ensure that $G$ has outer automorphism group of order 4, and that both $L_n(2):2$ and $S_d$ embed in $SO^\varepsilon_d(p)$ but not in $\Omega^\varepsilon_{d-1}(p)$. Hence we have the same configuration as in all the other examples above. \[\square\]

We have now shown that there is no bound on the Lie rank of those $G$ for which Aschbacher’s question has a negative answer. In these examples, there are two conjugacy classes of $L_n(2)$ in $\Omega^\varepsilon_{d-1}(p)$, and two conjugacy classes of $A_d$, interchanged by the diagonal automorphism. If instead $\varepsilon p \equiv 1 \mod 4$, then there are four classes of each, and the outer automorphism group of $\Omega^\varepsilon_{d-1}(p)$ is $D_8$. In \[2\], two of the reflections in $D_8$ are described as graph automorphisms $\gamma$, and the other two as $\delta \gamma$, but unfortunately the two conjugates of $\gamma$ are not distinguished from each other. For any particular choice of $\gamma$, two of the four classes of $A_d$ extend to $S_d$, and the other two classes are interchanged.

8. **Other classical groups**

So far, all our examples with $G$ a classical group have occurred when $G$ is in fact orthogonal. There is no bound on the characteristic, and there is no bound on the rank. All three families of orthogonal groups (plus type, minus type, and odd dimension) occur. It would be interesting to know if the other classical groups, linear, unitary or symplectic, can occur.
Of course, the isomorphisms $L_4(p) \cong \Omega_6^+(p)$ and $U_4(p) \cong \Omega^-_6(p)$ imply the existence of examples in linear and unitary groups, but do examples exist in linear and unitary groups of larger dimension? So far, I have not found any examples. The large outer automorphism groups in these cases make the analysis very delicate. There are potential examples of the form $L_3(4) < U_4(3) < L_6(p)$, but there are three classes of each of $L_3(4)$ and $U_4(3)$, and the embeddings between them are not given explicitly in [2]. Hence one needs extra detailed information to resolve these cases. It seems likely, however, that this configuration does not give any examples.

In the case of symplectic groups, over fields of odd prime order, the outer automorphism group has order 2, which is the ideal situation for us. If one looks through the tables of maximal subgroups of symplectic groups in dimensions up to 12 given in [2], one finds, besides the case $L_3(2) < A_7 < S_4(7)$ already discussed, just one series of potential examples, given by the embeddings $A_5 < L_2(p) < S_6(p)$ for $p$ a prime, $p \equiv \pm11, \pm19 \mod 40$. However, in this case the embedding of $2 \cdot A_5$ in $Sp_6(p)$ also goes via the tensor product $Sp_2(p) \circ GO_3(p)$, so this $A_5$ lies in more than two maximal subgroups of $Sp_6(p)$.

On the other hand, Anna Schroeder’s PhD thesis [8] contains the lists of maximal subgroups of $S_4(3)$ and their automorphism groups. There one finds two more potential infinite series of examples, given by the embeddings $J_3 < S_6(p) < S_4(3)$ and $L_2(13) < S_6(p) < S_{14}(p)$ for suitable primes $p$. The relevant congruences are $p \equiv \pm11, \pm19 \mod 40$ for $J_2$, and $p \equiv \pm3, \pm27, \pm29, \pm35, \pm43, \pm51 \mod 104$ for $L_2(13)$. It is straightforward to check, in the same way as before, that these do indeed give examples of negative answers to Aschbacher’s question.

**Theorem 10.** Let $p \equiv \pm11, \pm19 \mod 40$, and let $G = S_{14}(p)$. Let $H \cong J_2$ be a subgroup of $G$. Then $H$ is contained in exactly two maximal subgroups of $G$, both isomorphic to $S_6(p)$, and conjugate to each other in $G$.

**Theorem 11.** Let $p \equiv \pm3, \pm27, \pm29, \pm35, \pm43, \pm51 \mod 104$, and let $G = S_{14}(p)$. Let $H \cong L_2(13)$ be a subgroup of $G$ contained in $M \cong S_6(p)$. Then $H$ is contained in exactly two maximal subgroups of $G$, both conjugate to $M$.

9. Further remarks

Far-reaching as the above examples are, they have little, if any, impact on Aschbacher’s programme. This is because they all occur in sporadic or classical groups, whereas Aschbacher is only proposing to use this approach for exceptional groups of Lie type. Our examples therefore merely show that his question is still too broad, and that the question needs to be restricted to a smaller class of groups than the class of almost simple groups.

The maximal subgroups are known completely for five of the ten families of exceptional groups of Lie type, and, of the remaining five, $E_8$ seems least likely to be a source of examples, since it admits neither diagonal nor graph automorphisms. Similarly, $F_4$ admits no diagonal automorphisms, and admits a graph automorphism only in characteristic 2. Probably the most promising places to look for examples are in $E_6$ with a graph automorphism, and in $E_7$ with a diagonal automorphism.

On the other hand, it is entirely conceivable that no examples exist in the exceptional groups of Lie type.
Acknowledgements

I thank the Martin-Luther-Universität Halle-Wittenberg for a visiting professorship, during which the first version of this paper was written, and especially Professor Rebecca Waldecker, for inviting me, and arranging everything. I thank Rebecca Waldecker, Imke Toborg and Kay Magaard for fruitful discussions.
