Abstract: We calculate the one loop partition function for topologically massive higher spin gravity (TMHSG) for arbitrary spin by taking the spin-3 TMHSG action constructed in arXiv:1107.0915 and subsequently generalising it for an arbitrary spin. We find that the final result can be put into a product form which cannot be holomorphically factorized giving strong evidence that the topologically massive higher spin gravity is dual to a high spin extension of logarithmic CFT rather than a chiral one.

1. Introduction

Possibly the most viable testing ground for theories of quantum gravity has been three dimensional gravity in Anti de-Sitter space. Pure Anti de-Sitter gravity in three dimensions, as is well known, has no local propagating degrees of freedom. This feature can be remedied by adding a topological, gravitational Chern-Simons term to the action and then one can show that the linearised equations of motion become that of a massive scalar field. The theory goes under the name of Topologically Massive Gravity (TMG) [1, 2].

Through the celebrated AdS/CFT conjecture, there have been attempts to find the dual of the 3d AdS theory in terms of a conformal field theory. The field theory dual to the bulk Einstein theory in $AdS_3$ was initially conjectured to be an extremal CFT [3]. But a partition function computation by taking into account contributions from classical geometries and also including quantum corrections [4] showed that the expected holomorphic factorisation does not hold and there were other studies [5] which indicated that this conjecture was incorrect.

Motivated by [3], the authors of [4] looked at Einstein gravity in AdS, now modified by a gravitational Chern-Simons term, with a hope to obtain holomorphic factorization of the partition function. A study of asymptotic symmetries of pure AdS in [7] had lead to the construction of two copies of the Virasoro algebra with
central charges $c_\pm = 3\ell/2G$ (where $\ell$ is the AdS radius and $G$ the Newton’s constant in three dimensions). With the addition of the Chern-Simons term, the two copies of the Virasoro algebra still emerge as the asymptotic symmetry, but now with modified central charges $c_\pm = \frac{3\ell}{2G}(1 \mp \frac{1}{\mu \ell})$, where $1/\mu$ is the coefficient of the gravitational Chern-Simons term in the action as shown in [8, 9]. At the ‘chiral’ point $\mu \ell = 1$, one of the central charges vanishes and this led to the Chiral Gravity conjecture in [6]. The authors claimed that at this value of the coupling, the boundary theory dual to TMG in $AdS_3$ was a right-moving chiral CFT with a holomorphically factorizable partition function.

This conjecture was soon hotly debated (see, for example, the works [10]), and in [11, 12] it was shown that TMG at the chiral point was more generally dual to a Logarithmic Conformal Field Theory (LCFT) and that there were solutions which carried negative energy at the chiral point, thus invalidating the earlier conjecture. A more complete analysis in terms of holographic renormalisation techniques [13] was carried out and the results supported the latter claim of the duality to LCFT. One of the more robust checks of this conjecture was the recent computation of the one-loop partition function [14]. It was conclusively shown that there is no holomorphic factorisation of the one-loop partition function at the chiral point. The structure of the gravity calculation also matched with expectations from LCFT. The authors [14] found an exact matching with a part of the answer, viz. the single-particle excitations and offered substantial numerical evidence of the matching of the full partition functions.

Recently, there has been a renewed interest in theories of massless fields with spin greater than two in AdS spacetimes. It is known that these interacting higher spin theories are not sensible in flat spacetimes. Even in AdS, such theories generically require an infinite tower of fields with all possible spins to be consistent. Remarkably, in three dimensions, there can be a truncation to fields with spin less than and equal to $N$ for any $N$. It has been argued in [13, 17] on the basis of a Brown-Henneaux analysis that classically, these theories have an extended classical $W_N$ asymptotic symmetry algebra (see also the recent work [16]). A one-loop computation in [18], using the techniques developed in [19], showed that this symmetry is indeed perturbatively realised at the quantum level as well. This was an important ingredient in formulating the duality [20] between higher-spin theories and $W_N$ minimal models in the large-$N$ limit. There was also a subsequent work [21], in which the authors provided a bound on the amount of higher spin gauge symmetry present. This was regarded as a gravitational exclusion principle, where quantum gravitational effects
place an upper bound on the number of light states in the theory. Different tests of this duality have been performed successfully subsequent to its proposal, see [22].

The higher spin theories described above, like Einstein AdS gravity in three dimensions, do not have any propagating degrees of freedom. It is natural thus to ask if one can generalise Topologically Massive Gravity to theories of higher spin. We, in [23], initiated a construction of this theory, which we call Topologically Massive Higher Spin Gravity (TMHSG) (see also the overlapping work [24]). As a first step to this end, we studied the quadratic action for a spin-3 field in the linearised approximation about $AdS$ and obtained hints that the spin-3 theory at the so-called chiral point is dual to a logarithmic CFT. Specifically, we found that the space of solutions developed an extra logarithmic branch at the chiral point. In this paper, we shall perform a quantum test of this conjecture. In particular, we shall compute the one-loop partition function of the spin-3 theory on a thermal quotient of $AdS_3$ and show that it does not factorize holomorphically at the chiral point. Our analysis is along the lines of [14], and our results may be viewed as a higher-spin generalisation of theirs. We shall also compute the one-loop partition function for a spin-$N$ generalisation of the action proposed in [23] and show that this property continues to hold. We interpret these results as an indication that the dual CFT at the chiral point is not chiral, and that the results are consistent with the expectation of a high spin extension of a dual logarithmic CFT.

A brief overview of this paper is as follows. In section 2 we shall review the basic setup for the spin-3 calculation. We find that the one-loop partition function receives contributions from transverse traceless spin-3, spin-2 (coming from the ghost determinant) and transverse spin-1 modes (which is the trace of the spin-3 field). We compute the relevant one-loop determinants in section 3. We find that the spin-3 and spin-1 contributions referred to above contain terms (apart from the usual holomorphic ones inherited from the undeformed theory) which are non-holomorphic in $q \equiv e^{\tau i}$, where $\tau$ is the modular parameter on the boundary torus of thermal $AdS_3$. In particular, we find the contribution to the one loop partition function at the chiral point, from the spin-3 fields to be

$$Z_{TMHSG}^{(3)} = \prod_{n=3}^{\infty} \frac{1}{1-q^n} \prod_{m=3}^{\infty} \prod_{m=0}^{\infty} \frac{1}{1-q^m q^n} \prod_{k=4}^{\infty} \prod_{k=3}^{\infty} \frac{1}{1-q^k q^k}. \quad (1.1)$$

1We remind the reader that in [23] we had obtained non-gauge spin-1 excitations in the spectrum of the theory, which were not present in the undeformed theory. It is perhaps not surprising that we find an extra spin-1 contribution to the one-loop partition function of the theory as compared to that for the “massless” theory calculated in [18].
The first term is the holomorphic contribution determined from a study of the massless theory in [18], the other terms are non-holomorphic, and new. The middle term is the contribution from the transverse traceless spin-3 determinant, while the last term is the transverse spin-1 contribution coming from the trace of the spin-3 field.

As we can see from the spin-3 result that the one loop partition function is equivalent to the spectrum of the linearised equations of motion obtained by us in [23]. The contribution from the traceless spin-3 part to the partition function is from \((m, \bar{m}) = (3, 0)\) onwards which corresponds to the weights of the traceless primaries and its descendants as found in [23] and the contribution from the spin-1 trace is from \((k, \bar{k}) = (4, 3)\) onwards which corresponds to the weights of the trace primaries and its descendants as we found in [23]. Since the one loop calculation can be viewed as the partition function \(\text{Tr}(q^L \bar{q} L^0)\), in general, we must expect all physical modes that we saw in our classical analysis in [23] to show up in the one loop calculation with exactly the same weights. And this is what we get and hence our classical calculation in [23] and one loop calculations in the present paper are mutually consistent. \(^2\)

In the later part of the paper we discuss the case of general spins in section 4, where we find analogous results. The relevant excitations are transverse traceless spin-\(s\), spin-\(s - 1\) (coming from the ghost determinant), transverse traceless spin-\(s - 2\) ones (which is the trace of the spin-\(s\) field), transverse traceless spin-\(s - 3\) (coming from the longitudinal component of trace), transverse traceless spin-\(s - 4\) (coming from the longitudinal component of the longitudinal component of the trace) and so on up to transverse traceless spin-1, of which the spin-\(s\), \(s - 2\), \(s - 3\), \(\cdots\), 1 contribute non-holomorphically to the one-loop partition function. There are no other relevant excitations coming from the spin-\(s\) analysis because of the double-tracelessness condition reviewed, for example, in [13]. In section 5, we conclude with a brief interpretation of our results. We will also do a classical analysis for arbitrary spins in appendix A and show that the contributions to the partition function also appear in the classical spectrum.

2. The basic set up for \(s = 3\)

In this section we will compute the one loop partition function for spin 3 TMHSG, and in the process build up a mechanism to generalise our calculations to arbitrary spin in the subsequent section. Following the method adopted in [18], we shall compute the one-loop partition function in the Euclideanised version of theory \textit{via}

\(^2\)We thank Rajesh Gopakumar for mentioning this point to us.
the path integral
\[ Z^{(s)} = \frac{1}{\text{Vol(gauge group)}} \int [D\phi^{(s)}] e^{-S[\phi^{(s)}]}. \] (2.1)

In the one-loop approximation, only the quadratic part of the action \[ S[\phi^{(s)}] \] is relevant. This has been worked out for TMHSG, for the case of \( s = 3 \), in [23]. In the Euclidean signature it takes the form
\[ S = \frac{1}{2} \int d^3x \sqrt{g} \phi^{MNP} \left[ \hat{F}_{MNP} - \frac{1}{2} \hat{F}_{(Mg_{NP})} \right], \] (2.2)
where
\[ \hat{F}_{MNP} = D^{(M)} F_{MNP} \equiv F_{MNP} + \frac{i}{6\mu} \varepsilon_{RQM} \nabla^Q F^R_{NP}, \] (2.3)
and
\[ F_{MNP} = \Delta \phi_{MNP} - \nabla_{(M} \nabla^Q \phi_{NP)Q} + \frac{1}{2} \nabla_{(M} \nabla_{NP)} \phi_P - \frac{2}{\ell^2} g_{(MN}\phi_P). \] (2.4)

As always, the brackets “( )” denote the sum of the minimum number of terms necessary to achieve complete symmetrisation in the enclosed indices without any normalisation factor. Let us also define the operation of \( D^{(M)} \) on the trace of the spin-3 field by taking the trace of the expression in (2.3)
\[ D^{(M)} \phi_M = \phi_M + \frac{i}{6\mu} \varepsilon_{RQM} \nabla^Q \phi^R \] (2.5)

We now decompose the fluctuations \( \phi_{MNP} \) into transverse traceless \( \phi^{(TT)} \), trace \( \tilde{\phi}_M \) and longitudinal parts \( \nabla_{(M} \xi_{NP)} \) as\(^3\)
\[ \phi_{MNP} = \phi^{(TT)}_{MNP} + \tilde{\phi}_{(Mg_{NP)}} + \nabla_{(M} \xi_{NP)}. \] (2.6)

Following [18], we use gauge invariance, and orthogonality of the first two terms in (2.6) to decompose the action (2.2) as
\[ S[\phi_{MNP}] = S[\phi^{(TT)}_{MNP}] + S[\tilde{\phi}_M], \] (2.7)
where
\[ S[\phi^{(TT)}_{MNP}] = -\frac{1}{2} \int d^3x \sqrt{g} \phi^{(TT)MNP} \left[ -D^{(M)} \Delta \right] \phi^{(TT)}_{MNP}, \] (2.8)
and
\[ S[\tilde{\phi}_M] = \frac{9}{4} \int d^3x \sqrt{g} \left[ 8 \phi^M D^{(M)} \left( -\Delta + \frac{7}{\ell^2} \right) \phi_M - \phi^M D^{(M)} \nabla_M \nabla^Q \phi_Q \right]. \] (2.9)

\(^3\)Note that this decomposition is not orthogonal, in the sense that the trace part contains longitudinal terms, and the longitudinal part is not traceless. See [18].
Now one can further decompose \( \tilde{\phi}_M \) into its transverse and longitudinal parts as

\[
\tilde{\phi}_M = \tilde{\phi}^{(T)}_M + \nabla_M \chi.
\]

(2.10)

The action for \( \phi_M \) then becomes

\[
S[\tilde{\phi}_M] = \frac{9}{4} \int d^3 x \sqrt{g} \left[ 8 \tilde{\phi}^{(T)M} D^{(M)} \left( -\Delta + \frac{7}{\ell^2} \right) \tilde{\phi}^{(T)}_M + 9 \chi \left( -\Delta + \frac{8}{\ell^2} \right) (-\Delta) \chi \right].
\]

(2.11)

We see that the \( \chi \) part of the action is same as that obtained for the massless theory in [18] and will subsequently cancel with the relevant term coming from the ghost determinant, which arises from making the change of variables (2.6) in the path integral (2.1). The ghost determinant—being independent of the structure of the action—is essentially the same as that obtained [18], see their expression (2.14). This turns out to imply that although that the trace contribution does not cancel with the ghost determinant, the contribution coming from its longitudinal part does. This is in accordance with the observation in [23] that the trace in TMHS is not pure gauge unlike the massless theory. It is however still true even in the topologically massive theory that \( \nabla^M \phi_M \) is pure gauge and hence the longitudinal contribution from the trace \( \phi_M \) does cancel with the ghost determinant.

The spin-3 contribution to the one loop partition function for TMHS is given by

\[
Z^{(3)}_{TMHS} = Z_{gh}^{(3)} \times \left( \det[-\Delta]_{(3)}^{TT} \right)^{-\frac{1}{2}} \times \left( \det[-\Delta + \frac{7}{\ell^2}]_{(1)}^T \right)^{-\frac{1}{2}} \times \left( \det[-\Delta + \frac{8}{\ell^2}]_{(0)} \right)^{-\frac{1}{2}},
\]

(2.12)

where \( Z_{gh}^{(3)} \) is the ghost determinant arising as a Jacobian factor corresponding to the change of variables (2.6). The ghost determinant has been obtained in [18], see their expression (3.9), and is given by

\[
Z_{gh}^{(3)} = [\det[-\Delta + \frac{6}{\ell^2}]_{(2)}^T \times \det[-\Delta + \frac{7}{\ell^2}]_{(1)}^T \times \det[-\Delta + \frac{8}{\ell^2}]_{(0)}]^\frac{1}{2}.
\]

(2.13)

Therefore, the spin-3 contribution to the one loop partition function is given by

\[
Z^{(3)}_{TMHS} = \left[ \det[-\Delta]_{(3)}^{TT} \right]^{-\frac{1}{2}} \left[ \det[-\Delta]_{(1)}^T \right]^{-\frac{1}{2}} \left[ \det[-\Delta + \frac{6}{\ell^2}]_{(2)}^T \right]^{\frac{1}{2}} \equiv Z_{massless}^{(3)} Z^{(3)}_M,
\]

(2.14)

where \( Z_{massless}^{(3)} \) is the massless spin-3 partition function obtained in [18], which is

\[
Z_{massless}^{(3)} = \prod_{n=3}^{\infty} \frac{1}{1 - q^n}. \quad (2.15)
\]
It remains to determine $Z_{M}^{(3)}$. In order to do so, we shall follow the method of [14], and first calculate the absolute value $|Z_{M}^{(3)}|$. Following [14], we define

$$|Z_{M}^{(3)}| = \left[ \det (D_{(M)} \bar{D}_{(M)})^{T} \right]^{-\frac{1}{2}} \times \left[ \det (D_{(M)} \bar{D}_{(M)})^{T} \right]^{-\frac{1}{4}}. \quad (2.16)$$

The subscript (3) and (1) signifies that the operators are acting on transverse traceless spin-3 and transverse spin-1 respectively. Using (2.3) and (2.5), we can show that

$$D_{(M)} \bar{D}_{(M)} \phi^{TT}_{MNP} = -\frac{1}{4\mu^2} (\Delta + 4(\mu^2 - \frac{1}{\ell^2})) \phi^{TT}_{MNP},
$$

$$D_{(M)} \bar{D}_{(M)} \phi^{T}_{P} = -\frac{1}{36\mu^2} [-(\Delta + (36\mu^2 - \frac{2}{\ell^2})) \phi^{T}_{P}. \quad (2.17)$$

Therefore,

$$|Z_{M}^{(3)}| = \left[ \det \left( -\Delta + 4(\mu^2 - \frac{1}{\ell^2}) \right) \right]^{-\frac{1}{4}} \times \left[ \det \left( -\Delta + (36\mu^2 - \frac{2}{\ell^2}) \right) \right]^{-\frac{1}{4}}. \quad (2.18)$$

### 3. One-loop determinants for spin-3

We shall evaluate the one-loop determinants utilising the machinery developed in [19], according to which the relevant determinant takes the following form

$$-\log \det \left(-\Delta + \frac{m^2}{\ell^2}\right)^{TT} = \int_{0}^{\infty} \frac{dt}{t} K^{(s)}(\tau, \bar{\tau}; t)e^{-m^2t}, \quad (3.1)$$

where $K^{(s)}$ is the spin-$s$ heat kernel given by

$$K^{(s)}(\tau, \bar{\tau}; t) = \sum_{m=1}^{\infty} \frac{\tau_2}{4\pi t |\sin \frac{\tau_1}{2}|^2} \cos (sm\tau_1)e^{-\frac{m^2\tau_2^2}{4t}}e^{-(s+1)t}. \quad (3.2)$$

We therefore obtain

$$-\log \det \left(-\Delta + \frac{4(\mu^2\ell^2 - 1)}{\ell^2}\right)^{TT}_{(3)} = \sum_{m=1}^{\infty} \frac{1}{m} \cos (3m\tau_1)e^{-2\mu^2m\tau_2}
$$

$$= \sum_{m=1}^{\infty} \frac{2}{m} \frac{q^{3m} + \bar{q}^{3m}}{(1 - q^m)(1 - \bar{q}^m)}(qq)^{m(\mu - 1)}, \quad (3.3)$$

and similarly,

$$-\log \det \left[-\Delta + \frac{36\mu^2\ell^2 - 2}{\ell^2}\right]^{T}_{(1)} = \sum_{m=1}^{\infty} \frac{2}{m} \frac{q^m + \bar{q}^m}{(1 - q^m)(1 - \bar{q}^m)}(qq)^{3\mu m}. \quad (3.4)$$

We have used the notations and conventions of [13] throughout. We remind the reader that $q \equiv e^{i\tau}$, where $\tau = \tau_1 + i\tau_2$ is the complex structure modulus on the
boundary torus of thermal $AdS_3$. We can now put together all the contributions into
the expression for the one-loop partition function

$$
\log |Z_M^{(3)}| = -\frac{1}{4} \log \det \left( -\Delta + \frac{4(\mu^2 l^2 - 1)}{l^2} \right)^{TT} - \frac{1}{4} \log \det \left[ -\Delta + 36\mu^2 l^2 - 2 \right]^{T}\n\]

$$

$$
= \sum_{m=1}^{\infty} \frac{1}{2m} \frac{q^{3m} + \bar{q}^{3m}}{(1 - q^m)(1 - \bar{q}^m)} (q\bar{q})^{m(\mu - 1)} + \sum_{m=1}^{\infty} \frac{1}{2m} \frac{q^m + \bar{q}^m}{(1 - q^m)(1 - \bar{q}^m)} (q\bar{q})^{3\mu m}.
\]

(3.5)

Following [14], we infer from this that at the chiral point we have (after rewriting
$$
\log |Z_M^{(3)}| = \frac{1}{2} \log Z_M^{(3)} + \frac{1}{2} \log \bar{Z}_M^{(3)}
\]

$$

$$
\log Z_M^{(3)} = \sum_{m=1}^{\infty} \frac{1}{m} \frac{(q^{3m} + (q\bar{q})^{3m} q^m)}{(1 - q^m)(1 - \bar{q}^m)}.
\]

(3.6)

Let us now note that

$$
\sum_{n=1}^{\infty} \frac{1}{n} \frac{q^{3n}}{(1 - q^n)(1 - \bar{q}^n)} = -\sum_{m=3}^{\infty} \sum_{\bar{m}=0}^{\infty} \log (1 - q^m \bar{q}^{\bar{m}})
\]

$$

$$
\sum_{n=1}^{\infty} \frac{1}{n} \frac{(q\bar{q})^{3n} q^n}{(1 - q^n)(1 - \bar{q}^n)} = -\sum_{m=3}^{\infty} \sum_{\bar{m}=3}^{\infty} \log (1 - q^{m} \bar{q}^{\bar{m}}),
\]

(3.7)

and hence the spin-3 contribution to the full partition function at the chiral point,
factorizes as (after including the massless contribution from [18])

$$
Z_{TMHSG}^{(3)} = \prod_{n=3}^{\infty} \frac{1}{1 - q^n} \prod_{m=3}^{\infty} \prod_{\bar{m}=0}^{\infty} \frac{1}{1 - q^m \bar{q}^{\bar{m}}} \prod_{k=4}^{\infty} \prod_{k=3}^{\infty} \frac{1}{1 - q^{k} \bar{q}^{k}}.
\]

(3.8)

This is the expression (1.1) that we had mentioned in the introduction. As noted
there, the partition function does not factorize holomorphically. A chiral CFT would
not give rise to such a partition function. We therefore take this as a one-loop clue
that the dual CFT to TMHSG is indeed not chiral, but logarithmic. We remind the
reader that an analogous result was found in [14] for the case of topologically massive
gravity, from which the authors were able to conclude that the dual CFT was indeed
logarithmic.

4. Generalisation to arbitrary spin

In this section, we will consider a natural generalisation of our spin-3 action (2.2) to
an arbitrary spin-$s$ field. We will perform the analysis of Sections [3] and [3] and show
that holomorphic factorisation does not occur. We take the action\footnote{In principle, as mentioned in [23], we can obtain the quadratic action for topologically massive spin-N fields from the Chern-Simons formulation of the theory with unequal levels. However, this action is a natural extension of the spin-2 and the spin-3 actions, and since the structure is fixed by gauge invariance, the action that follows from the Chern-Simons formulation with unequal levels should give rise to the same action. The Chern-Simons formulation should also fix the normalisation of parity violating C-S term in (4.2) which was fixed by demanding uniqueness of the chiral point.}

\[ S = \frac{1}{2} \int d^3x \sqrt{\text{det} g} \phi^{M_1 M_2 \ldots M_s} \left[ \hat{F}_{M_1 M_2 \ldots M_s} - \frac{1}{2} \hat{F}_P (M_1 \ldots M_{s-2} g_{M_s M_{s-1}} \hat{F}_P) \right], \quad (4.1) \]

where

\[ \hat{F}_{M_1 \ldots M_s} = D^{(M)} F_{M_1 M_2 \ldots M_s} \equiv F_{M_1 \ldots M_s} + \frac{i}{s(s-1)\mu} \varepsilon^{QR(M_1} \nabla^Q F_{R M_2 \ldots M_s)}, \quad (4.2) \]

and

\[ F_{M_1 M_2 M_3 \ldots M_s} \equiv \Delta \phi_{M_1 M_2 \ldots M_s} - \nabla_{(M_1} \nabla^Q \phi_{M_2 \ldots M_s) Q} + \frac{1}{2} \nabla_{(M_1} \nabla_{M_2} \phi_{M_3 M_4 \ldots M_s)} P^P \]

\[ - \frac{1}{\ell^2} \left\{ \left[ s^2 - 3s \right] \phi_{M_1 M_2 \ldots M_s} + 2g_{(M_1 M_s \phi_{M_2 M_3 \ldots M_s) P} P} \right\}. \quad (4.3) \]

The normalisation \( \frac{1}{s(s-1)} \) in equation (4.2) is fixed by demanding that even in the spin-N case, the chiral point remains \( \mu \ell = 1 \). One can check that the spin-\( s \) generalised action (4.1) is invariant under the gauge transformation \( \phi_{M_1 \ldots M_s} \rightarrow \phi_{M_1 \ldots M_s} + \nabla_{(M_1} \xi_{M_2 \ldots M_s)} \) where \( \xi_{M_2 \ldots M_s} \) is a symmetric-traceless gauge parameter.

Now we would like to consider the possibility that the higher-spin theory with spins up to \( N \) is also dual to a high spin extension of LCFT. One would then expect that along the lines of what we have seen for spin-3, the one-loop partition function again would not factorize holomorphically. We will now do a one-loop analysis using the action (4.1) with this goal in mind. An essential ingredient for this analysis – as in the case of spin-3 – is the action of \( D^{(M)} \) on symmetric transverse traceless (STT) tensors of rank \( s \) and below. Using the definition of \( D^{(M)} \) in (4.2), one can show that

\[ \mathcal{D}^{(M)} \mathcal{D}^{(M)} \phi_{M_1 \ldots M_s}^{(TT)} = \frac{1}{(s-1)^2 \mu^2} \left[ -\Delta + \frac{m_s^2}{\ell^2} \right] \phi_{M_1 \ldots M_s}^{(TT)}, \]

\[ \mathcal{D}^{(M)} \mathcal{D}^{(M)} \phi_{M_1 \ldots M_s}^{(s-2,TT)} = \frac{(s-2)^2}{(s-1)^2 \mu^2} \left[ -\Delta + \frac{m_{s-2}^2}{\ell^2} \right] \phi_{M_1 \ldots M_s}^{(s-2,TT)}, \]

\[ \mathcal{D}^{(M)} \mathcal{D}^{(M)} \chi_{M_1 \ldots M_s}^{(s-m,TT)} = \frac{(s-m)^2}{(s-1)^2 \mu^2} \left[ -\Delta + \frac{m_{s-m}^2}{\ell^2} \right] \chi_{M_1 \ldots M_s}^{(s-m,TT)}. \quad (4.4) \]
where
\[ m_s^2 = \mu^2 \ell^2 (s-1)^2 - (s+1), \]
\[ m_{s-m}^2 = \mu^2 \ell^2 \frac{s^2(s-1)^2}{(s-m)^2} - (s-m+1), \quad s > m \geq 2. \] (4.5)

Here \( \phi^{(s-2)} \) and \( \chi^{(s-n)} \) are STT tensors of rank \( s-2 \) and \( s-n \) respectively, where \( n \geq 3 \).

Following the same steps as for spin-3 in the previous section, the one loop partition function can be factorized as
\[ Z^{(s)}_{TMHS} = Z^{(s)}_{\text{massless}} Z^{(s)}_M, \] (4.6)

The contributions to \( Z^{(s)}_M \) come from the determinants of \( \mathcal{D}^{(M)} \) acting on \( \phi^{(T\!T)}, \phi^{(s-2,T\!T)} \) and \( \chi^{(s-m,T\!T)} \) (for \( s > m \geq 3 \)). This is apparent from (4.4), which suggests that \( \mathcal{D}^{(M)} \) acts non trivially on the STT modes of spin-1 and higher. The action of \( \mathcal{D}^{(M)} \) stops at \( \chi^{(1)} \) as it acts trivially on scalars, being just the identity map. After a careful analysis, one sees that
\[ \log |Z^{(s)}_M| = -\frac{1}{4} \log \det \left( -\Delta + \frac{m_s^2}{\ell^2} \right)^{(T\!T)}(s) - \frac{1}{4} \sum_{m=2}^{s-1} \log \det \left( -\Delta + \frac{m_{s-m}^2}{\ell^2} \right)^{(T\!T)}(s-m). \] (4.7)

We find, using the spin-\( s \) heat kernel (3.2) and the expression (3.1) for the determinant,
\[ -\log \det \left( -\Delta + \frac{m_s^2}{\ell^2} \right)^{(T\!T)}(s) = \sum_{m=1}^{\infty} \frac{2}{m} \left( \frac{m^{(s-1)}(\mu \ell - 1)}{1 - |q|^2} \right) \left( q^m + q^{m^s} \right), \]
\[ -\log \det \left( -\Delta + \frac{m_{s-m}^2}{\ell^2} \right)^{(T\!T)}(s-m) = \sum_{n=1}^{\infty} \frac{2}{n} \left( q^n \right)^{|k(s,m,\mu \ell)|} \left( q^{n(s-m)} + q^{n(s-m)} \right). \] (4.8)

Where,
\[ k(s, m, \mu \ell) = \frac{s(s-1)\mu \ell - (s-m)(s-m-1)}{2(s-m)}. \] (4.9)

At the chiral point \( \mu \ell = 1 \), it becomes
\[ k(s, m, 1) \equiv k(s, m) = \frac{s(s-1) - (s-m)(s-m-1)}{2(s-m)} = \frac{m(2s-m-1)}{2(s-m)}, \] (4.10)

and hence at the chiral point the partition function \( Z^{(s)}_M \) becomes
\[ \log Z^{(s)}_M = \sum_{n=1}^{\infty} \frac{1}{n} \left( q^{sn} + \sum_{m=2}^{s-1} (q^n)^{k(s,m)n} q^{(s-m)n} \right). \] (4.11)
After using the identities
\[ \sum_{n=1}^{\infty} \frac{1}{n} \frac{q^n}{(1-q^n)(1-q^n)} = - \sum_{m=0}^{\infty} \sum_{m=1}^{\infty} \log (1 - q^m q^n), \]
\[ \sum_{n=1}^{\infty} \frac{1}{n} \frac{(q q)^{k(s,m)} q^{(s-m)n}}{(1-q^n)(1-q^n)} = - \sum_{p=r(s,m)}^{\infty} \sum_{p=k(s,m)}^{\infty} \log (1 - q^p q^p), \]
(4.12)

where,
\[ r(s, m) = k(s, m) + s - m = \frac{s(s - 1) + (s - m)(s - m + 1)}{2(s - m)}, \]
(4.13)
the contribution to the full partition function from spin-\( s \) field at the chiral point, becomes
\[ Z_{\text{TMHSG}}^{(s)} = \prod_{n=s}^{\infty} \frac{1}{|1-q^n|^2} \prod_{m=s}^{\infty} \prod_{m=0}^{\infty} \frac{1}{(1-q^m q^m)} \prod_{t=2}^{s-1} \prod_{t=2}^{\infty} \prod_{p=r(s,t)}^{\infty} \prod_{p=k(s,t)}^{\infty} \frac{1}{(1-q^p q^p)}. \]
(4.14)

Hence, the full partition function at the chiral point, in a theory with fields of spin \( s = 3, \ldots, N \) in addition to the spin 2 graviton, becomes
\[ Z_{\text{TMHSG}} = \prod_{s=2}^{N} \left[ \prod_{n=s}^{\infty} \frac{1}{|1-q^n|^2} \prod_{m=s}^{\infty} \prod_{m=0}^{\infty} \frac{1}{(1-q^m q^m)} \right] \times \left[ \prod_{s=3}^{N} \prod_{t=2}^{s-1} \prod_{t=2}^{\infty} \prod_{p=r(s,t)}^{\infty} \prod_{p=k(s,t)}^{\infty} \frac{1}{(1-q^p q^p)} \right], \]
Where
\[ k(s, m) = \frac{s(s - 1) - (s - m + 1)(s - m - 1)}{2(s - m)}, \quad r(s, m) = k(s, m) + s - m \]
(4.15)

We will see in appendix [A] that \( r(s, m) \) and \( k(s, m) \) appear respectively as left and right weights of classical left moving primary solution (or massive primary at the chiral point). In particular, we will also see that, \( r(s, m, \mu \ell) \equiv k(s, m, \mu \ell) + s - m \), and \( k(s, m, \mu \ell) \) will be the weights of massive primary at a generic point. Thus we also see that for generic spins, our one loop computations and classical computations are also mutually consistent.

Note that the first square bracket contribution starts from \( s = 2 \) whereas the second square bracket contribution starts from \( s = 3 \). This is a novel feature of topologically massive higher spin theory and technically this comes from the fact the trace is not a pure gauge. As the spin increases, the factors contributing to the partition function also increases. This, as discussed before, comes from the fact that longitudinal component of trace, longitudinal components of the longitudinal components of the trace and so on are not pure gauge and starts contributing till one hits a scalar, which is a pure gauge and the contribution terminates.
One might be worried about the fact that $k(s, m)$ and $r(s, m)$ in (4.15) are not integers for generic spin, and this might not be consistent with the periodicity in $\tau$. However one might note that $r(s, m) - k(s, m) = s - m$, which is an integer and hence the periodicity in $\tau$ is not affected because of the following identity

$$q^{r(s,m)}q^{-k(s,m)} = (qq^{-1})^{k(s,m)}q^{s-m}. \tag{4.16}$$

5. Conclusions

In this paper, motivated by the results of [23], we computed the one loop partition function for topologically massive higher spin gravity (TMHSG) for spin-3 and later generalised it to arbitrary spin. We find that the one loop partition function does not factorize holomorphically giving strong evidence that the dual theory is a high spin extension of LCFT. This was also anticipated in the classical calculation for spin-3 TMHSG in [23] as extra logarithmic modes emerged at the chiral point. Although this result might be tantalising, a CFT interpretation of the result would make the proposal of a high spin extension of dual LCFT more concrete.

We had speculated on the possible realisation of the symmetry algebra in [23]. One of our speculations was that since the classical $W_3$ algebra at the chiral point seems to become singular due to the presence of the inverse of the central charge in the coefficient of the non-linear term in the $[W,W]$ commutator, we should look at a contraction of this algebra which would effectively reduce this to a Virasoro algebra. While this was a perfectly correct limit, we also suggested that this could be a rather restrictive realisation. Our analysis in this paper shows that in addition to the non-holomorphic factorisation and a contribution from the trace modes, what we obtain in the 1-loop partition function at the chiral point is the vacuum character of the $W_3$, for the spin-3 case and a similar $W_N$ vacuum character for the spin-$N$ generalisation. This indicates conclusively that the $W$-algebra exists in the chiral limit and does not simply reduce to the Virasoro algebra. This also adds strength to another of our speculations in [23], viz. at the chiral point one needs to consider the quantum version of the $W_3$, where the problematic coefficient of the non-linear term gets a shift and hence is not singular at the chiral point.

This also gives rise to the expectation that we would see novel logarithmic behaviour in the $W$-algebra and not the Virasoro alone. Another piece of evidence of the emergent logarithmic nature of the $W$-algebra at the chiral point comes from looking at the OPE of the $W$-algebra. Let us concentrate of the $W_3$ for the moment. The quantum $W_3$ introduced by Zamolodchikov in [25] contains two generators, the
energy-momentum tensor $T(z)$ and $W(z)$, where $W(z)$ is a primary of spin 3 with respect to $T(z)$. The OPE of $W(z)$ with itself is given by

$$W(z)W(w) \sim \frac{c/3}{(z-w)^6} + \frac{2T(w)}{(z-w)^4} + \frac{\partial T(w)}{(z-w)^3} + \frac{2\beta \Lambda(w) + 3/10 \partial^2 T(w)}{(z-w)^2} + \frac{\beta \partial \Lambda(w) + 1/15 \partial^3 T(w)}{(z-w)^1}$$

(5.1)

where $\Lambda(w) = TT(w) - 3/10 \partial^2 T(w)$ and $\beta = \frac{16}{5c+22}$. From here we can read off the two-point function

$$\langle W(z)W(w) \rangle = \frac{c/3}{(z-w)^6}$$

(5.2)

The left-moving central charge of the $W_3$ at the chiral point vanishes and this also means that the two-point function of $W(z)$ vanishes here. This is a clear indication of a logarithmic CFT and we expect the following structure:

$$\langle W(z)W(0) \rangle = 0, \quad \langle W(z)w(0,0) \rangle = \frac{b_w}{z^6}$$

(5.3)

$$\langle w(z, \bar{z})w(0,0) \rangle = \frac{1}{z^6} \left( B_w - b_w \log m^2 |z|^2 \right)$$

(5.4)

where $w(z, \bar{z})$ is the logarithmic partner of $W(z)$. $b_w$ is a characterising feature of the LCFT, whereas $B_w$ can be got rid of by a field redefinition. It would be very interesting to see if this expected structure actually emerges from a more thorough analysis in the gravitational set-up generalising the relevant computation done for spin-2 in [13, 12]. It is plausible that given the complicated structure of the 1-loop partition function that we have obtained here with the additional pieces from the novel trace terms, we would get a richer structure in the logarithmic CFT duals to the TMHSG. We leave addressing this issue for future work.

Before we conclude, we would like to remind the reader of a few important observations that follow from the results in the present paper. The fact that the 1-loop partition function does not holomorphically factorize gives support to the claim that the the dual to TMHSG is a high spin extension of a logarithmic CFT, and not a chiral one. Additionally there is the presence of a non trivial spin one contribution (in case of spin 3 TMHSG) in the one loop partition function. This points to the fact that the trace modes cannot be gauged away, both of which results are in accordance with our analysis of classical solutions in [23].

A. Classical analysis for generic spins

In this appendix, we will study the classical analysis for generic spins and show that $k(s, m, \mu \ell)$ \[^{[4,9]}\] and $r(s, m, \mu \ell) \equiv k(s, m, \mu \ell) + s - m$ will appear as weights (right and left respectively) of massive primaries in the linearised spectrum of generic spins.

The classical equation of motion for a generic spin is

$$\hat{F}_{M_1 \ldots M_s} \equiv \mathcal{D}^{(M)} \mathcal{F}_{M_1 M_2 \ldots M_s} \equiv \mathcal{F}_{M_1 \ldots M_s} + \frac{1}{s(s-1)} \varepsilon_{QR(M_1} \nabla^Q \mathcal{F}^{R}_{M_2 \ldots M_s}) = 0, \quad (A.1)$$

where

$$\mathcal{F}_{M_1 M_2 M_3 \ldots M_s} \equiv \Delta \phi_{M_1 M_2 \ldots M_s} - \nabla_{(M_1} \nabla^Q \phi_{M_2 \ldots M_s)Q} + \frac{1}{2} \nabla_{(M_1} \nabla_{M_2} \phi_{M_3 M_4 \ldots M_s)P}^P - \frac{1}{\ell^2} \left\{ \left[ s^2 - 3s \right] \phi_{M_1 M_2 \ldots M_s} + 2 g_{(M_1 M_2} \phi_{M_3 M_4 \ldots M_s)P}^P \right\}. \quad (A.2)$$

Using the field redefinition and the gauge condition defined below,

$$\phi_{M_1 \ldots M_s} = \tilde{\phi}_{M_1 \ldots M_s} - \frac{1}{s} g_{M_1 M_2} \tilde{\phi}^{(s-2)}_{M_3 \ldots M_s},$$

$$\nabla^M \tilde{\phi}_{M M_2 \ldots M_s} = \frac{1}{2} \nabla_{(M_2} \tilde{\phi}^{(s-2)}_{M_3 \ldots M_s)}, \quad (A.3)$$

we can write

$$\mathcal{F}_{M_1 M_2 M_3 \ldots M_s} = \mathcal{D}^{(L)} \mathcal{D}^{(R)} \tilde{\phi}_{M_1 \ldots M_s}, \quad (A.4)$$

where

$$\mathcal{D}^{(L)} \tilde{\phi}_{M_1 \ldots M_s} \equiv \tilde{\phi}_{M_1 \ldots M_s} + \frac{\ell}{s(s-1)} \varepsilon_{QR(M_1} \nabla^Q \tilde{\phi}^{R}_{M_2 \ldots M_s)},$$

$$\mathcal{D}^{(R)} \tilde{\phi}_{M_1 \ldots M_s} \equiv \tilde{\phi}_{M_1 \ldots M_s} - \frac{\ell}{s(s-1)} \varepsilon_{QR(M_1} \nabla^Q \tilde{\phi}^{R}_{M_2 \ldots M_s}). \quad (A.5)$$

One can now check that the equations of motion implies that

$$g_{M_1 M_2} \nabla^M_3 \ldots \nabla^M_s \tilde{F}_{M_1 \ldots M_s} = 0 \quad \Rightarrow \quad g_{M_1 M_2} \nabla^M_3 \ldots \nabla^M_s \mathcal{F}_{M_1 \ldots M_s} = 0 \quad \Rightarrow \quad \nabla^M_3 \ldots \nabla^M_s \tilde{\phi}_{M_3 \ldots M_s}^{(s-2)} = 0. \quad (A.6)$$

Now let us write down the massive branch equation $\mathcal{D}^{(M)} \tilde{\phi} = 0$, by operating on it from the left by $\mathcal{D}^{(M)}$ which is the same as $\mathcal{D}^{(M)}$ with $\mu$ replaced by $-\mu$. By replacing
\( \mu \ell = \pm 1 \) on the solutions obtained here, we can recover the left and right branch solutions. The equations are

\[
\begin{align*}
\Delta \tilde{\phi}_{M_1 \ldots M_s} - \frac{m_s^2}{\ell^2} \tilde{\phi}_{M_1 \ldots M_s} &= \frac{(2s - 3)}{2s^2} \nabla_{(M_1} \nabla_{M_2} \tilde{\phi}_{M_3 \ldots M_s}^{(s-2)}) + \frac{1}{\ell^2 s^2} (s^2 - s + 2) g(M_1 M_2) \tilde{\phi}_{M_3 \ldots M_s}^{(s-2)}, \\
\Delta \tilde{\phi}_{M_3 \ldots M_s}^{(s-2)} - \frac{m_{s-2}^2}{\ell^2} \tilde{\phi}_{M_3 \ldots M_s}^{(s-2)} &= \frac{(2s - 5)}{(s - 2)} \nabla_{M_3} \chi_{M_4 \ldots M_s}^{(s-3)} - \frac{2}{(s - 2)^2} g(M_3 M_4 \chi_{M_5 \ldots M_s}^{(s-4)}), \\
\Delta \chi_{M_4 \ldots M_s}^{(s-3)} - \frac{m_{s-3}^2}{\ell^2} \chi_{M_4 \ldots M_s}^{(s-3)} &= \frac{(2s - 7)}{(s - 3)^2} \nabla_{(M_4} \nabla_{M_5} \chi_{M_6 \ldots M_s}^{(s-4)} - \frac{2}{(s - 3)^2} g(M_4 M_5 \chi_{M_6 \ldots M_s}^{(s-5)}), \\
\vdots & \\
\Delta \chi_{MN}^{(2)} - \frac{m_2^2}{\ell^2} \chi_{MN}^{(2)} &= \frac{3}{4} \nabla_{(M} \chi_{N)}^{(1)}, \\
\Delta \chi_{M}^{(1)} - \frac{m_1^2}{\ell^2} \chi_{M}^{(1)} &= 0,
\end{align*}
\]

(A.7)

where

\[
\chi^{(s-m)} = \nabla_{M_1} \ldots \nabla_{M_{s-m}} \tilde{\phi}_{M_1 \ldots M_s}^{(s-2)},
\]

and \( m_s \) and \( m_{s-m} \) are given in (1.5). The procedure to solve the above equations is same as the spin-3 analysis done in [23]. We need to start with the last equation of (A.7), the solution of which would be given by \( h - \bar{h} = \pm 1 \), where \( h \) and \( \bar{h} \) are the left and right weights. We will put the solution of \( \chi^{(1)} \) into the equation of \( \chi^{(2)} \) and decompose \( \chi^{(2)} \) into two parts, one carrying the weights of \( \chi^{(1)} \) and the other would be transverse, the solution of which would be given by \( h - \bar{h} = \pm 2 \). Following the steps similarly we will decompose \( \chi^{(3)} \) into three parts, one carrying the weight of \( \chi^{(1)} \), another carrying the weights of transverse \( \chi^{(2)} \) and a part which is transverse on its own carrying weight \( h - \bar{h} = \pm 3 \). In this way we will finally obtain the full solution. We are not interested in obtaining the explicit form of the final solution (although there is no technical obstacle in doing so). We will, however, be interested in obtaining the weights of the different modes present in the final solution. For that it is sufficient (as per the argument above) to analyse the transverse traceless parts of the equations (A.7). For that let us write the Laplacian acting on traceless rank-s tensor as

\[
\Delta \phi_{M_1 \ldots M_s} = \left[ -\frac{2}{\ell^2} (L^2 + \bar{L}^2) - \frac{s(s+1)}{\ell^2} \right] \phi_{M_1 \ldots M_s}
\]

(A.9)

Where, \( L^2 \) and \( \bar{L}^2 \) are the left and right \( SL(2, R) \) casimirs of the isometry group of \( AdS_3 \) (see eq 4.11 and 4.12 of [23]). The eigenvalues of \( L^2 \) and \( \bar{L}^2 \) are given by \( h(1-h) \) and \( \bar{h}(1-\bar{h}) \), where \( h \) and \( \bar{h} \) are the left and right weights of the solution. We will
also use the fact that for a rank-$s$, transverse traceless primary, $h - \bar{h} = \pm s$. Thus the different modes of equation (A.7), will carry weights $h - \bar{h} = \pm s$, $h - \bar{h} = \pm (s - 2)$, $h - \bar{h} = \pm (s - 3)$, · · · , $h - \bar{h} = \pm 1$. By using (A.7) and (A.9), we obtain the weights of the different modes as

\begin{align}
  h - \bar{h} &= +s : \quad h = \frac{s^2 (\mu \ell + 1) - s (\mu \ell - 1)}{2s}, \quad \bar{h} = \frac{s(s - 1)(\mu \ell - 1)}{2s}, \\
  h - \bar{h} &= -s : \quad h = \frac{s(s - 1)(\mu \ell - 1)}{2s}, \quad \bar{h} = \frac{s^2 (\mu \ell + 1) - s (\mu \ell - 1)}{2s}, \\
  h - \bar{h} &= +(s - m) : \quad h = \frac{(s - m + 1)(s - m) + s(s - 1)\mu \ell}{2(s - m)} = r(s, m, \mu \ell), \quad \bar{h} = \frac{s(s - 1)\mu \ell - (s - m - 1)(s - m)}{2(s - m)} = k(s, m, \mu \ell), \quad (s - 1) \geq m \geq 2, \\
  h - \bar{h} &= -(s - m) : \quad h = k(s, m, \mu \ell), \quad \bar{h} = r(s, m, \mu \ell), \quad (s - 1) \geq m \geq 2 \quad (A.10)
\end{align}

The modes with negative $h - \bar{h}$ will not belong to the massive branch (they appear because we had the operation of $\bar{D}^{(M)}$ on the original equation of motion). But these modes will become the right branch solution by taking $\mu \ell = 1$. The modes with positive $h - \bar{h}$ will belong to the massive branch solution. For $\mu \ell = 1$, they will become the left branch solutions. These are the weights that also appear in the one loop partition function at the chiral point (4.15).
