Abstract
The liver is contributed to maintaining body iron homeostasis and controlling of body adaptation to fasting. Although previous studies implied a negative relationship between iron and ghrelin in both mice and humans, it remains to be explored whether fasting or ghrelin has a functional effect on iron homeostasis in the liver. In this study, we examined the roles of fasting and ghrelin in modulating the protein expression of Fpn1, transferrin receptor 1 (TfR1), and ferritin light chain (Ft-L), as well as the mRNA expression of ghrelin, hepcidin, ghrelin O-acyltransferase (GOAT), and growth hormone secretagogue receptor 1 alpha (GHSR1α) in mouse liver and cultured hepatocytes. Our in vivo results suggested that fasting significantly upregulated the mRNA expression of ghrelin, GOAT, and GHSR1α, as well as the protein levels of ghrelin, Fpn1, and Ft-L, but not TfR1, in mouse liver. Interestingly, mRNA expression of hepcidin did not change significantly after fasting. Meanwhile, in cultured hepatocytes, ghrelin significantly increased the protein expression of Fpn1 but not Ft-L and TfR1 and significantly enhanced ERK phosphorylation. Furthermore, the pretreatment of cultured hepatocytes with either a pERK inhibitor or a GHSR1α antagonist abolished the effects of ghrelin on Fpn1 expression and ERK phosphorylation. Our findings confirmed that fasting increases iron export in the liver by upregulating Fpn1 expression through the ghrelin/GHSR1α/MAPK signaling pathway.

Introduction
The liver is considered the central organ in maintaining body iron homeostasis because it is not only a major iron storage compartment but also the site where hepcidin, the key peptide that controls iron export and regulates iron metabolism, is synthesized [1]. In addition, the liver is considered a regulator of body adaptation to fasting [2]. During fasting, profound changes occur in the liver to reduce energy use and limit catabolism, including changes in hormones such as ghrelin [3]. Ghrelin, which is mainly produced and secreted by P/D1 cells of the stomach and contains 28 amino acids [4], can be increased during energy restriction and fasting and may affect appetite and eating behaviors [5]. This hormone functions in the brain and regulates food consumption and glucose metabolism; therefore, it is related to body weight changes and fatness [6–9]. It is also observed to activate the orexigenic neural circuits and modulate the systemic metabolism [8, 10], and
it also functions in central and peripheral tissues, promoting appetite, enhancing gastrointestinal tract motility, and exerting anti-inflammatory effects, among others. Ghrelin has two forms and becomes active only after being acylated by ghrelin O-acyltransferase (GOAT), which catalyzes the attachment of the eight-carbon fatty acid octanoyl to the Ser3 side chain of the peptide ghrelin [11–13].

Ghrelin enhances appetite and promotes food consumption during starvation [14–16]. Poor appetite is one of the obvious clinical characteristics of iron deficiency anemia (IDA) [17] and perpetuates a state of starvation [18, 19]. These characteristics were consistent with the finding that IDA might be attributable to decreased ghrelin levels [20, 21], which suggested potential correlations between ghrelin and changes in iron metabolism. An investigation in prepubertal children also observed significantly lower iron contents and ghrelin levels in IDA groups than in healthy controls [22]. Another study on the changes of iron and ghrelin in different phases of IDA (hypoferritinemia/iron deficiency/iron deficiency anemia) in children also confirmed that both iron content and ghrelin levels are decreased in the plasma and reached their minimum levels in the last stage of IDA [17].

An investigation by Dogan et al. suggested that while children suffering from IDA showed lower levels of serum hepcidin and ghrelin than healthy children, iron treatment significantly elevated the hepcidin and ghrelin levels in the serum of IDA children [23]. In our previous study, a statistically significant negative correlation was also found between ghrelin and hepcidin levels and ghrelin in the serum [24]. Based on these findings, we hypothesized that ghrelin may modulate the balance of iron homeostasis under physiological conditions. In this study, we examined the effects of fasting and of ghrelin on the protein or mRNA expression of ghrelin, GHSR1α, GOAT, ferroportin 1 (Fpn1), transferrin receptor 1 (TfR1), and ferritin light chain (Ft-L) in the liver and/or cultured hepatocytes. Moreover, we examined the roles of GHSR1α antagonist and phosphorylated extracellular-regulated protein kinase (pERK) inhibitor in the expression of Fpn1 and pERK in cultured hepatocytes. Our results demonstrated that fasting or ghrelin was able to increase Fpn1 expression via the ghrelin/GHSR1α/MAPK signaling pathway in the liver and cultured hepatocytes.

Materials and Methods

Animals and Materials

Unless otherwise stated, all chemicals and reagents used in this study were purchased from Sigma (St. Louis, MO, USA). Ghrelin was obtained from BioVision (4990-1000, CA, USA). All mice were supplied by the animal experimental center of Nantong University. All mice used were housed in stainless steel cages with 55–60% relative humidity at 21 ± 2 °C with alternating 12-h periods of light and dark. All animal handling procedures were conducted in accordance with guidelines approved by the Laboratory Animal Ethics Committee of Nantong University.

Animal Fasting Treatment

Eight-week-old male C57BL/6J mice were assigned randomly by weight to groups and were fasted for 0, 6, or 24 h prior to tissue sample collection. The mice were anesthetized intraperitoneally with 1% pentobarbital sodium (40 mg/kg body weight) and received myocardial perfusion using phosphate-buffered saline (PBS), after which liver tissues were collected for measurements.

Isolation and Culture of Mouse Hepatocytes

Cultured hepatocytes were obtained from male C57BL/6J mice by a two-step collagenase IV perfusion procedure [25]. Livers from C57BL/6 mice were first perfused with preperfusion buffer via the portal vein for 15 min, followed by 0.1 mg/mL collagenase IV dissolved in enzyme buffer at 37 °C until the liver capsule was incised. After a sufficient amount of time (approximately 20 min) for liver tissue digestion, the thick fibrous connective tissues were discarded. The suspension was filtered and centrifuged to collect the hepatocytes. Then, the hepatocytes were seeded in six-well plates (~2 × 10^6 cells/well) and cultured in Dulbecco’s modified Eagle’s medium with 10% fetal bovine serum (GIBCO), penicillin (100 units/ml), and streptomycin (100 μg/ml) and cultured at 37 °C in a 5% CO2 incubator. For ghrelin treatment, cultured hepatocytes were incubated with ghrelin (100 nM) or PBS (control) for 0.5–3 h, and then the cells were washed with PBS and lysed to obtain RNA or proteins. For determining the effects of GHSR1α antagonist and pERK inhibitor, cultured hepatocytes were pretreated with D-(lys-3)-GHRP-6 (Sigma, St. Louis, MO, USA) at 100 nM or U0126 (Selleck, Houston, TX, USA) at 10 μM for 1 h, followed by 10^{-7} M ghrelin. The dosages and time points of ghrelin, GHSR1α antagonist, and U0126 for hepatocytes were referred as our previous research [26].

Total RNA Extraction and Semiquantitative and Quantitative Real-Time PCR

Total RNA was isolated and extracted from tissues and cells using the TRIzol extraction method. A total of 1 μg of RNA was reverse transcribed by the HiScript II Q RT SuperMix for qPCR (+gDNA wiper) Kit according to the manufacturer’s instructions to obtain cDNA. Quantitative real-time PCR (qPCR) was performed using the FastStart Universal SYBR Green Master Mix (Vazyme Biotech Co., Ltd., China) in an
Fasting Increases Iron Export by Modulating Ferroportin 1 Expression Through the Ghrelin/GHSR1α/MAPK... | Springer

LC96 instrument (Roche, Switzerland). The primer sequences (Sangon Biological Engineering Technology & Services Co., Ltd., Shanghai, China) [26] used in this study are listed below (Table 1). The CT values of each target gene were normalized to those of β-actin in each group. Finally, the relative expression of mRNA was determined using the 2^ΔΔCT method.

**Western Blot Analysis**

Proteins from cells or tissue were extracted and homogenized with RIPA lysis buffer (Beyotime, PRC) and sonicated by a sonifier [27]. The BCA (Pierce, Rockford) detection method was employed to determine the protein contents. A sample containing 30 μg of protein was loaded and run in each well of SDS-PAGE gels. The membranes were incubated with primary antibodies (1:1000) for TIR1 (Life Technology), Fpn1 (Novus), ferritin-L (ProteinTech), pERK against 42/44 (Cell Signaling Technology), ERK (Cell Signaling Technology), ghrelin (Abcam), and GHSR1α (Abcam) at 4 °C overnight. Blots were then performed with a secondary antibody of goat anti-rabbit or anti-mouse IRDye 800 CW at 1:10000 dilution (Li-Cor, Lincoln Co., Ltd., USA) at room temperature for 1 h. The band densities of the specific blots were scanned and analyzed with ImageJ software. β-Actin monoclonal antibody (Sigma, 1:10000) was used as a loading control.

**Immunofluorescence**

Liver samples were fixed with 10% neutral formaldehyde and embedded in paraffin. The specimens were sectioned at a thickness of 5 μM and then blocked for 2 h in blocking TBS buffer containing 3% bovine serum albumin (BSA, Sigma), and finally incubated with GHSR1α primary antibody (1:400) at 4 °C overnight. Immunoreactivity was examined by incubation with Alexa Fluor 488 conjugated secondary antibody at 4 °C overnight. The fluorescence signals were detected using an SP8 confocal laser scanning microscope (Leica, Germany).

**Immunohistochemistry**

Liver samples were fixed with 10% neutral formaldehyde and embedded in paraffin. The specimens were sectioned at a thickness of 5 μM and then incubated at 58 °C for 3 h followed by xylene treatment for dewaxing, hydrated through an alcohol gradient, and washed with PBS. A microwave was used to repair the antigens at 650 W for 20 min, and the samples were then cooled to room temperature. Then, the cells were exposed to 3% H2O2 and normal goat serum (GBICO) for 10 min to block the activity of endogenous catalase and nonspecific binding. Finally, the slice specimens were incubated with ghrelin antibody (Cell Signaling Technology, 1:250) overnight at 4 °C. Ghrelin immunoreactions were detected with the enhanced biotin-streptavidin immunoperoxidase technique. Diaminobenzidine was used as the chromogenic substrate, followed by hematoxylin counterstaining. Five slices of each group were chosen for determining the distribution and expression of ghrelin in the liver under a light microscope. Five visual fields were selected randomly in each slice for statistical analysis by ImageJ software (Media Cybernetics, Silver Spring, USA).

**Statistical Analysis**

Statistical analyses were executed with GraphPad Prism 7.0 software. All the data are presented as the mean ± SEM. The variation between the means in each group was analyzed by one-way analysis of variance (ANOVA), and Tukey’s post hoc test was then performed for multiple comparisons. A probability value of \( p < 0.05 \) was considered statistically significant.

**Results**

**GHSR1α Was Expressed in the Mouse Liver and Hepatocytes**

As a G protein-coupled receptor, GHSR is present mainly existing in the hypothalamus and pituitary [9, 28]. Two isoforms of GHSR have been reported [29], GHSR1α [30, 31] and GHSR1β [32, 33]. However, GHSR1α is responsible for ghrelin-induced endocrine effects and some nonendocrine effects. Here, we first examined whether GHSR1α is expressed in mouse liver and cultured hepatocytes. The results of q-PCR and Western blot analyses both confirmed that the liver (Fig. 1a and b) and cultured hepatocytes (Fig. 1c and d) expressed GHSR1α mRNA and protein, although at lower levels than the hypothalamus.

Fasting Induced Ghrelin, GHSR1α, and GOAT mRNA Expression, But No Effect on Hepcidin in the Liver

To investigate whether and how fasting affects the ghrelin/GHSR system, mice were fasted for 0, 6, or 24 h, and the livers were collected to measure the expression of ghrelin, GHSR1α, GOAT, and hepcidin (Fig. 2a–d). The q-PCR results demonstrated that ghrelin (Fig. 2a) and GOAT mRNA (Fig. 2c) were significantly increased after fasting. Compared with the control group, the mRNA expression of ghrelin, GOAT, and GHSR1α all increased significantly after fasting for 24 h (Fig. 2a, b, and c). However, hepcidin mRNA expression was not significantly increased after fasting (Fig. 2d). The
Western blot results also suggested that ghrelin protein expression in the liver was increased after fasting for 6 and 24 h (Fig. 3a and b). Furthermore, immunohistochemistry analysis showed that ghrelin protein was mainly expressed around the veins in the liver (Fig. 3c). In addition, GHSR1α, which was mainly located on the membrane, was also increased in the liver after 24 h of fasting (Fig. 3d). These results confirmed that although ghrelin is mainly expressed in the stomach, it may also be expressed in other tissues, which was consistent with the results in the previous study [34].

**Fpn1, But Not TfR1 or Ft-L, Was Upregulated and Combined with an Increase of pERK Expression in Both the Liver and Cultured Hepatocytes**

To determine whether fasting or ghrelin treatment affects the iron-related proteins in the liver or cultured hepatocytes, we then explored the role of fasting or ghrelin treatment in the expression of the three pivotal proteins involved in the mediation of cellular iron-related proteins, namely, Fpn1, TfR1, and Ft-L. The Western blot results demonstrated that the expression levels of Ft-L (Fig. 4a, b, e, and f) and Fpn1 detected using IF (d) before (the control) and after 6 or 24 h of fasting as described in the Materials and Methods section. Data are presented as the mean ± SD (n = 5). *p < 0.05, **p < 0.01, and ***p < 0.001 versus control.
Fig. 4 Fasting significantly increased the protein expression of Fpn1 and Ft-L in the liver. The protein levels of Ft-L (b, f), Fpn1 (c, g), and TfR1 (d, h) in mouse liver were measured by Western blotting before fasting (control) and after fasting for 6 (a) or 24 h (b). Data are presented as the mean ± SD (n = 6–7). *p < 0.05, **p < 0.01, and ***p < 0.001 versus control.

(Fig. 4a, c, e, and g) in mouse liver were increased after fasting, while the TfR1 protein levels remained unchanged (Fig. 4a, d, e, and h). Western blot analysis also demonstrated that 24 h of fasting significantly increased ERK phosphorylation, while 6 h of fasting failed to induce any change (Fig. 5). Meanwhile, in vitro treatment of cultured hepatocytes with $10^{-7}$ M ghrelin for 0.5 h or 1 h also induced significant increases in Fpn1 expression (Fig. 6a and d) and ERK phosphorylation (Fig. 6b and f). However, the expression of Ft-L (Fig. 6a and c) and TfR1 (Fig. 6a and e) in cultured hepatocytes treated with ghrelin did not change at any time point tested.

Fig. 5 Fasting significantly enhanced ERK phosphorylation in the liver after fasting for 24 h. The expression of pERK in mouse liver was detected by Western blotting before (the control) and after 6 (a, c) or 24 h (b, d) of fasting as described in the Materials and Methods section. Data are presented as the mean ± SD (n = 7–8). *p < 0.05, **p < 0.01, and ***p < 0.001 versus control.
Ghrelin-Induced Increases in ERK Phosphorylation and Fpn1 Expression Were Suppressed by GHSR1α Antagonist or MAPK Signaling Pathway Inhibitor

To clarify the possible mechanisms by which fasting and ghrelin regulate Fpn1 protein expression, we further studied the effects of a GHSR1α antagonist (D-(lys-3)-GHRP-6) and a pERK inhibitor (U0126) on the phosphorylation of ERK and the expression of Fpn1 and Ft-L. Cultured hepatocytes were pretreated with D-(lys-3)-GHRP-6 at 100 nM or U0126 at 10 μM for 1 h, followed by 10^{-7} M ghrelin. The results indicated that D-(lys-3)-GHRP-6 significantly inhibited the ghrelin-stimulated upregulation of both pERK (Fig. 7a and b) and Fpn1 (Fig. 7c and d) expression but did not change Ft-L expression (Fig. 7e and f). U0126 also suppressed ghrelin-induced increases in both pERK (Fig. 7f and g) and Fpn1 (Fig. 7h and i) expression in cultured hepatocytes, although there were no differences in the expression of Ft-L or TfR1 (Fig. 7j and k).

Discussion

The liver is the key tissue for iron storage and regulation under physiological conditions [35]. Here, we investigated whether ghrelin could influence iron homeostasis, and...
fasting- or ghrelin-induced changes in iron-related proteins were identified in both liver and cultured hepatocytes. In addition, several primary iron metabolism-related proteins are reflected in the liver and hepatocytes, including Fpn1, TfR1, and ferritin (Ft). TfR1 is an essential receptor that contributes to cellular iron uptake. Fpn1 is the only distinct cellular iron exporter known to date. Two isoforms of Ft are responsible for iron storage but with different functions, namely, Ft heavy chain (Ft-H) and Ft light chain (Ft-L). Specifically, Ft-L is more

Fig. 7  GSHR1α inhibitor D-(lys-3)-GHRP-6 or pERK inhibitor (U0126) significantly suppressed ghrelin-induced Fpn1 upregulation in hepatocytes, while Ft-L and TfR1 were not affected by ghrelin. Hepatocytes were pretreated with 100 nM D-(lys-3)-GHRP-6 for 1 h or 10 μM U0126 for 6 h, followed by treatment with ghrelin (10^{-7} M) for another 0.5 h. The phosphorylation of ERK (a, b, f, and g) and the expression of Fpn1 (c, d, h, and i) and Ft-L (c, e, h, and j) were detected by Western blotting. Data are presented as the means ± SD (n = 3). *p < 0.05, **p < 0.01, and ***p < 0.001 versus control.
related to cellular iron storage [36]. Therefore, Fpn1 and TfR1 were investigated as markers of changes in iron uptake and release, while Ft-L was examined as an iron content marker in the liver/hepatocytes.

In our study, we observed that 6 or 24 h of fasting significantly upregulated the mRNA expression of ghrelin, GHSR1α, and GOAT as well as the protein levels of Fpn1 and Ft-L in mouse liver. However, TfR1 expression increased after fasting for 6 h and decreased after 24 h. The increases in Ft-L and Fpn1 expression suggested that fasting enhanced both iron storage and iron export in the liver. Fpn1, as a hepcidin receptor, could be downregulated by hepcidin [37, 38]. However, there were no changes in hepcidin mRNA after fasting at any time point, suggesting that hepcidin may not play a prominent regulatory role in liver Fpn1 expression under fasting conditions.

As ghrelin expression increased and was mainly distributed around the veins, and the membrane-bound receptor GHSR1α also increased in the liver after fasting for 24 h, we hypothesized that the effect of fasting on Fpn1 and Ft-L expression in the liver might be regulated by the binding and activation of the ghrelin/GHSR1α system. To determine whether these changes were induced by the activation of GHSR1α in the liver by ghrelin, primary cultured hepatocytes were employed here. Treatment with ghrelin for 0.5 or 1 h showed a significant increase in Fpn1 expression in cultured hepatocytes. However, ghrelin failed to impact TfR1 or Ft-L expression. Furthermore, ghrelin-induced Fpn1 upregulation was suppressed by the GHSR1α antagonist D-(lys-3)-GHRP-6. These findings proved the involvement of the ghrelin/GHSR1α pathway in the regulation of Fpn1 expression in cultured hepatocytes.

It has been confirmed that the proliferative role of ghrelin is related to the activation of its downstream MAPK signaling cascade in multiple types of cells [39, 40]. Our previous investigation also suggested that Fpn1 expression increased after ERK phosphorylation in the spleen/macrophages [26]. Here, we further explored the role of ghrelin in ERK phosphorylation in the presence or absence of a MAPK signaling pathway inhibitor (U0126). The results showed that ERK phosphorylation in cultured hepatocytes was significantly enhanced after ghrelin treatment for 1 h, while pretreatment with the pERK inhibitor U0126 suppressed the positive role of ghrelin in the expression of Fpn1 and phosphorylation of ERK. Together with the identification results from PCR and Western blot analyses showing that GHSR1α is expressed in the liver and cultured hepatocytes, all of these results confirm the hypothesis that ghrelin increases Fpn1 expression through the GHSR/MAPK signaling pathway in the liver/hepatocytes.

In summary, we confirmed that ghrelin significantly affects iron homeostasis in mouse liver by modulating iron-regulating proteins, as fasting or ghrelin upregulated Fpn1 expression via activation of the GHSR/MAPK signaling pathway. However, the reason that fasting and ghrelin do not affect TfR1 expression in the spleen and liver both in vivo and in vitro remains to be investigated further.

Authors’ Contributions G.H.W. and L.Z. conceived, organized, and supervised the work; Q.Q.L., J.N.H., and G.Y. performed the experiments; X.Y.Y., Z.P.C., D.W., and Y.P.L. contributed to the analysis of data; Q.Q.L. and G.H.W. prepared, wrote, and revised the manuscript.
