Abstract
Intracholecystic papillary neoplasm (ICPN) of the gallbladder is a premalignant lesion. An ICPN arising from the cystic duct is rare. A woman in her 60s exhibited dilatation of the common bile duct on computed tomography (CT) performed for screening of respiratory disease. The CT revealed an enhancing mass, 3.3 cm in diameter, in the cystic duct. Endoscopic ultrasonography showed a well-demarcated, hyperechoic mass in the dilated cystic duct. Endoscopic retrograde cholangiography showed that the common bile duct was slightly retracted by the dilated cystic duct. Cytological analysis of the bile juice did not show any evidence of malignancy. She was diagnosed with a cystic bile duct tumor suggestive of ICPN. Cholecystectomy, resection of the extrahepatic bile duct, and lymph node dissection were performed. Macroscopically, the papillary-proliferated tumor was localized to the cystic duct. No critical lesions were evident in the common bile duct. Histologically, the tumor in the cystic duct showed intraluminal growth with a papillary configuration without malignancy. Based on these findings, the tumor was diagnosed as an ICPN. We encountered a rare case of ICPN localized to the cystic duct of the gallbladder.

Introduction

Intracholecystic papillary neoplasm (ICPN) was first documented as a premalignant lesion of the gallbladder in the World Health Organization (WHO) classification of tumors of the gallbladder and extrahepatic bile ducts published in 2010 [1]. In 2012, Adsay et al. [2] proposed the term intracholecystic papillary-tubular neoplasm for a precancerous lesion of the gallbladder with papillary or tubular growth patterns. In 2019, WHO classified benign epithelial tumors and precursors of the gallbladder and extrahepatic bile ducts as adenoma, biliary intraepithelial neoplasia, ICPN, and intraductal papillary neoplasm of the bile duct [3]. ICPNs have been defined recently and are rare. In the biliary system, the cystic duct is included in the gallbladder and not in the extrahepatic bile duct. Moreover, an ICPN located in the cystic duct of the gallbladder is extremely rare. Herein, we report a case of ICPN arising from the cystic duct.

Case Presentation

A female patient in her 60s visited a clinic regularly. She had rheumatoid arthritis, hypertension, and an ovarian cyst. Dilatation of the common bile duct was incidentally detected on computed tomography performed to screen for respiratory disease. Therefore, she was referred to our hospital for further examination. Laboratory findings were within the reference range, except for slight elevation in the levels of alkaline phosphatase, aspartate aminotransferase, alanine aminotransferase, and C-reactive protein. The levels of tumor markers such as carcinoembryonic antigen and carbohydrate antigen 19-9 were within the reference range. Computed tomography revealed an enhancing mass, 3.3 cm in diameter, in the cystic duct of the gallbladder (Fig. 1a, b). The mass in the cystic duct of the gallbladder exhibited a low-intensity signal on T1-weighted imaging (Fig. 1c), a slight high-intensity signal on T2-weighted imaging (Fig. 1d), and a high-intensity signal on diffusion-weighted imaging (Fig. 1e). Magnetic resonance cholangiopancreatography showed a tumor-like defect in the dilated cystic duct (Fig. 1f). Positron emission tomography revealed localized accumulation of fludeoxyglucose (4.2 F) in the cystic duct tumor (Fig. 2a). Endoscopic ultrasonography showed a well-demarcated, hyperechoic mass in the dilated cystic duct. The common bile duct showed no abnormalities other than slight dilatation (Fig. 2b). Endoscopic retrograde cholangiography (ERC) showed that the common bile duct was slightly retracted by the dilated cystic duct (Fig. 2c). Cytological analysis of the bile juice did not show any evidence of malignancy. Based on these findings, she was diagnosed with a cystic bile duct tumor, suggestive of ICPN. However, considering the malignant nature and extent of spread of the tumor to the junction of the common bile duct, we planned and performed cholecystectomy, resection of the extrahepatic bile duct, and lymph node dissection. Frozen sections of the stump of the common bile duct did not show any evidence of malignancy. Macroscopically, the papillary-proliferated tumor was localized to the cystic duct (Fig. 3a). No critical lesions were noticed in the common bile duct. Histologically, the tumor in the cystic duct showed intraluminal growth with a papillary configuration and was noninvasive (Fig. 3b, c). Therefore, this tumor was diagnosed as ICPN with low-grade intraepithelial neoplasia because of the localization of the gallbladder lesion to the cystic duct. On immunohistochemical examination (Fig. 3d–g), the tumor cells of ICPN localized to the cystic duct reacted with MUC-5AC and MUC-6, reacted slightly with MUC-2 but did not react with MUC-1. The tumor showed gastric morphology, typically resembling gastric foveolar epithelium with elongated interconnecting glands lined by tall columnar cells. Therefore, the histological pattern of ICPN was classified as gastric foveolar type.

The patient was discharged 9 days after surgery without any complications. She had no recurrence for 2 years after the resection.
Discussion

In 2010, WHO classification of tumors of the gallbladder classified precursors and early lesions of the gallbladder cancer as ICPN [1]. Papillary lesions involving the gallbladder are referred to as ICPN. ICPN is defined as a grossly visible, mass-forming, noninvasive, epithelial neoplasm arising in the mucosa, and projecting into the lumen of the gallbladder [3].

The mean age of patients with ICPN in most reports is 60 years [2, 4–6]. The majority of patients are females, with a female: male ratio of 3:1 to 6:1 [2, 5–7]. Approximately 50%
of patients with ICPN present with pain in the right upper quadrant of the abdomen. The remaining 50% of the patients are asymptomatic [2]. This case was of a woman in her 60s who was asymptomatic. Approximately one-third of ICPNs are multifocal. The median tumor size is 2.2 cm [2]. Dilatation of the bile ducts, and sometimes, cystic dilatations are observed. Hypersecretion or luminal accumulation of mucin may occasionally occur. In this case, ERC showed only defects caused by the tumor without any mucinous formations.

The tumor in the cystic duct shows irregular papillary proliferation with a fern-leaf-like structure, and it is noninvasive. **e** Immunohistochemical findings of ICPN. **f** MUC-1, **g** MUC-2, **h** MUC-5AC, **i** MUC-6. H&E, hematoxylin and eosin.
According to the degree of atypia in the epithelium, ICPNs are classified as low-grade lesions (mild to moderate atypia) or high-grade lesions (noninvasive papillary carcinoma). Four phenotypes of ICPNs are histologically and immunohistochemically recognized: biliary, gastric, intestinal, and oncocytic types [3]. Gastric ICPNs comprise two subtypes: gastric foveolar and gastric pyloric types. In the gastric foveolar type, tall columnar cells of the gastric region are diffusely positive for MUC-5AC, while some may express MUC-6 [2, 8]. In the gastric pyloric type, smaller tubular glands are diffusely and strongly positive for MUC-6 [2]. In our case, microscopically, there were no destructive findings. While the tumor had diffuse and strong co-immunoreactivity for both MUC-5AC and MUC-6, the tumor showed a gastric morphology, typically resembling the gastric foveolar epithelium with elongated interconnecting glands lined by tall columnar cells containing abundant mucin. Therefore, the tumor in our patient was diagnosed as ICPN of gastric foveolar type with low-grade intraepithelial neoplasia.

Although the ICPN of the cystic duct was diagnosed preoperatively, considering the possibility of malignant transformation, we performed cholecystectomy with resection of the extrahepatic bile duct and lymph node dissection. Pathological examination did not reveal any malignant lesions. However, histological analysis of the frozen sections showed borderline atypia. As it is difficult to diagnose malignant lesions intraoperatively using frozen sections, we believe that the choice of the surgical procedure was appropriate. According to the UICC TNM classification, cystic duct cancer is categorized as the gallbladder cancer. Therefore, this case was diagnosed as ICPN because of the presence of a gallbladder lesion, and not intraductal papillary neoplasm of the bile duct.

Some studies have reported cases of ICPN originating from the cystic duct [9–11]. However, these cases include tumors that involved the common bile duct and were not localized to the cystic duct. To the best of our knowledge, this is the first report of ICPN localized to the cystic duct. In conclusion, we report an extremely rare case of ICPN localized to the cystic duct of the gallbladder.
