Abstract:

We study complexified elliptic Calogero-Moser integrable systems. We determine the value of the potential at isolated extrema, as a function of the modular parameter of the torus on which the integrable system lives. We calculate the extrema for low rank $B, C, D$ root systems using a mix of analytical and numerical tools. For $so(5)$ we find convincing evidence that the extrema constitute a vector valued modular form for the $\Gamma_0(4)$ congruence subgroup of the modular group. For $so(7)$ and $so(8)$, the extrema split into two sets. One set contains extrema that constitute vector valued modular forms for congruence subgroups (namely $\Gamma_0(4), \Gamma(2)$ and $\Gamma(3)$), and a second set contains extrema that exhibit monodromies around points in the interior of the fundamental domain. The former set can be described analytically, while for the latter, we provide an analytic value for the point of monodromy for $so(8)$, as well as extensive numerical predictions for the Fourier coefficients of the extrema. Our results on the extrema provide a rationale for integrality properties observed in integrable models, and embed these into the theory of vector valued modular forms. Moreover, using the data we gather on the modularity of complexified integrable system extrema, we analyse the massive vacua of mass deformed $\mathcal{N} = 4$ supersymmetric Yang-Mills theories with low rank gauge group of type $B, C$ and $D$. We map out their transformation properties under the infrared electric-magnetic duality group as well as under triality for $\mathcal{N} = 1^*$ with gauge algebra $so(8)$. We compare the exact massive vacua to those found in a semi-classical analysis, and find surprising properties of the quantum gauge theories.

# 1 Introduction

Four-dimensional gauge theories accurately describe forces of nature. Since solving them is hard, we may revert to studying supersymmetric four-dimensional gauge theories, in which the power of holomorphy lends a helping hand. Twenty years ago, we realised how to solve for the low-energy effective action on the Coulomb branch of $\mathcal{N} = 2$ gauge theories in four dimensions \[1, 2\]. The solution techniques were soon recognised to lie close to those studied in integrable systems \[3, 4\]. It is the bridge between integrable models and supersymmetric gauge theories that we will further explore in this paper. We also attempt to reinforce both sides separately, and present results in a manner such that the contributions to these two domains may be read independently.

The link between supersymmetric gauge theories and integrable systems was useful in writing down the low-energy effective action for $\mathcal{N} = 2^*$ gauge theory, namely $\mathcal{N} = 4$ super Yang-Mills theory with gauge group $G$, broken to $\mathcal{N} = 2$ supersymmetry by adding a mass term for one hypermultiplet. For the gauge group $G = SU(N)$ this program was completed in terms of a Hitchin integrable system with $SL(N, \mathbb{C})$ bundle over a torus with puncture \[5\]. The associated elliptic Calogero-Moser system permits generalisations to any root system, and allows for twists, which were used to provide Seiberg-Witten curves and differentials for $\mathcal{N} = 2^*$ theory with general gauge group $G$ \[6\]. The generalisation was non-trivial since the elegant technique of lifting to M-theory \[7\] is difficult to implement in the presence of orientifold planes (see e.g. \[8, 9\]), while the relevant generalised Hitchin integrable system has a gauge group which is related to the gauge group of the Yang-Mills theory in an intricate manner \[10\]. For a review of part of the history, see the lectures \[11\].

We will be interested in breaking supersymmetry further, from $\mathcal{N} = 2$ to $\mathcal{N} = 1$ by adding another mass term for the remaining chiral multiplet (providing us with three massive chiral multiplets of arbitrary mass). We will study this $\mathcal{N} = 1^*$ gauge theory with gauge group $G$. With $\mathcal{N} = 1$ supersymmetry, we hope to calculate the effective superpotential $W$ at low energies exactly. For an adjoint mass deformation from $\mathcal{N} = 2$ to $\mathcal{N} = 1$ this was done in the original work \[1\] in certain cases. For $\mathcal{N} = 1^*$ and gauge group $G = SU(N)$, the exact superpotential was proposed in \[12\] following the...
techniques of \[\text{[13]}\]. The superpotential is the potential of the complexified elliptic Calogero-Moser integrable system associated to the root lattice of type \(A_{N-1}\). In \[\text{[14]}\] the exact superpotential for \(N = 1^*\) with more general gauge algebra was argued to be the potential of the twisted elliptic Calogero-Moser system with root lattice associated to the Lie algebra of the gauge group \(G\).

In this paper, we wish to analyse the proposed exact superpotential in more detail. This involves a study of the properties of the isolated extrema of the complexified and twisted elliptic Calogero-Moser integrable system. The results are of independent interest, and we have therefore dedicated a first part of this paper to the study of the integrable systems per se.

The paper is structured as follows. In section 2 we review the relevant elliptic Calogero-Moser models. We pause to demonstate a Langlands duality between the \(B\) and \(C\) type integrable systems. We then analyse the isolated extrema of the complexified potential of low rank integrable systems of \(B, C\) and \(D\) type, and their modular properties. We observe the strong connection to vector valued modular forms. The latter in turn provide a natural backdrop for integrality properties of integrable systems (see e.g. \[\text{[15, 16, 17]}\]). Section 2 is the technical heart of the paper, and we will lay bare many properties of the vector valued modular forms, using a combination of analytical work and extensive numerics. We will analytically describe the potential in certain classes of extrema. We also find sets of extrema that exhibit a monodromy in the interior of the fundamental domain. In these cases we are able to calculate the monodromy, as well as to provide extensive numerical data for the integer valued coefficients describing the value of the potential at the extrema.

Finally, in section 3 we reinterpret the results we obtained in terms of the physics of massive vacua of \(N = 1^*\) theories. We compare our results for the quantum theory to semi-classical results for massive vacua, and discuss electric-magnetic duality properties in the infrared under the modular group as well as the Hecke group. For \(so(8)\), we also detail the action of the global triality symmetry on the massive vacua. We will see various confirmations of semi-classical results, as well as multiple surprises. We conclude in section 4 and argue that we have only scratched the surface of a broad field of open problems.

## 2 Elliptic Integrable Systems and Modularity

It is interesting to identify and study dynamical systems that are integrable. Often they form solvable subsectors of more complicated theories of even more physical interest. There exist one-dimensional models of particles with interactions that are integrable, and the Calogero-Moser models of our interest are one such class \[\text{[18, 19, 20]}\]. These models are associated to root systems of Lie algebras (amongst others). See e.g. \[\text{[21, 22]}\] for a review. Integrable systems are also known to have certain integrality properties. Namely, their minimal energy, frequencies of small oscillations as well as eigenvalues of Lax matrices are often expressed in terms of a series of integers \[\text{[15, 16, 17]}\].

In this section, we study properties of (twisted) elliptic Calogero-Moser systems. We analyse the complexified model, defined on a torus with modular parameter \(\tau\). In particular, we examine the extrema of the complexified potential, and exhibit their curious characteristics.

### 2.1 The Elliptic Calogero-Moser models

The member of the pyramid of Calogero-Moser integrable systems we concentrate on is the elliptic Calogero-Moser model. We concentrate on the models associated with a root system \(\Delta\), as well as their twisted counterparts. These models have a Hamiltonian with rank \(r\) variables, with canonical kinetic term, and a potential of the form:

\[
V_\Delta = g \sum_{\alpha \in \Delta} \varphi(\alpha(X); \omega_1, \omega_2),
\]

where \(\varphi\) is the Weierstrass elliptic function on a torus with periods \(2\omega_1\) and \(2\omega_2\) and \(g\) is a coupling constant. We choose the half-periods such that the imaginary part of the modular parameter \(\tau = \omega_2/\omega_1\) is positive\(^2\). The vector \(X\) lives in the space dual to the root lattice of rank \(r\) and the sum in the potential is over all the roots \(\alpha\) of the root system \(\Delta\). The model is integrable for all Lie algebra root systems. The twisted elliptic Calogero-Moser model is defined in terms of twisted Weierstrass functions:

\[
\varphi_n(x; \omega_1, \omega_2) = \sum_{k \in \mathbb{Z}_n} \varphi(x + \frac{k}{n} 2\omega_1; \omega_1, \omega_2),
\]

which are summed over shifts by fractions of periods (thus in effect modifying that period). We have a twisted elliptic Calogero-Moser model for all non-simply laced root systems and the value of \(n\) is then

\(^2\)See appendix B for more on our conventions for elliptic functions.
given by the ratio of the length squared of the long versus the short roots. We will be interested in the twisted elliptic Calogero-Moser model with potential:

\[ V_{\Delta,tw} = g_l \sum_{\alpha_l \in \Delta_l} \varphi(\alpha_l(X); \omega_1, \omega_2) + g_s \sum_{\alpha_s \in \Delta_s} \varphi_n(\alpha_s(X); \omega_1, \omega_2), \]  

(2.3)

where \( \alpha_l \) denote the long and \( \alpha_s \) the short roots in the root system \( \Delta = \Delta_l \cup \Delta_s \), and \( g_l \) and \( g_s \) are two coupling constants. We will concentrate on the classical root systems \( A_r, B_r, C_r, D_r \) corresponding to the classical algebras \( su(r+1), so(2r+1), sp(2r) \) and \( so(2r) \). We allow complex values for the components of the vector \( X \) (i.e. \( X \in \mathbb{C}^r \)).

### 2.2 Langlands Duality

Beyond the many features of these integrable systems already discussed in the literature, the first supplementary property that will be pertinent to our study of isolated extrema, is their behaviour under an inversion of the modular parameter \( \tau \). We therefore briefly digress in this subsection to discuss a few of the details of the duality. Models associated to simply laced Lie algebras map to themselves under the modular \( S \)-transformation \( S : \tau \rightarrow -1/\tau \). This is easily confirmed using the transformation rule \( \text{[B.3]} \) of the Weierstrass \( \wp \) function under modular transformations. We do have a non-trivial Langlands or short-long root duality between the twisted elliptic Calogero-Moser model of \( B \)-type and the twisted \( \wp_x \inversion of the modular parameter \( \text{[B.3]} \).complementary property that will be pertinent to our study of isolated extrema, is their behaviour under an inversion of the modular parameter \( \tau \). We therefore briefly digress in this subsection to discuss a few of the details of the duality. Models associated to simply laced Lie algebras map to themselves under the modular \( S \)-transformation \( S : \tau \rightarrow -1/\tau \). This is easily confirmed using the transformation rule \( \text{[B.3]} \) of the Weierstrass \( \wp \) function under modular transformations. We do have a non-trivial Langlands or short-long root duality between the twisted elliptic Calogero-Moser model of \( B \)-type and the twisted model of \( C \)-type. In order to exhibit the duality, we make the potential for the (twisted) \( B_r = so(2r+1) \) theory more explicit:\[ V_B = b_l \left[ \sum_{i<j} \varphi(x_i - x_j; \omega_1, \omega_2) + \varphi(x_i + x_j; \omega_1, \omega_2) \right] + b_s \left[ \sum_{i=1}^r \varphi(x_i; \omega_1, \omega_2) + \varphi(x_i + \omega_1; \omega_1, \omega_2) \right], \]

and for the \( C_r = sp(2r) \) theory as well:

\[ V_C = c_s \left[ \sum_{i<j} \varphi(y_i - y_j; \omega_1', \omega_2') + \varphi(y_i + y_j; \omega_1', \omega_2') + \varphi(y_i - y_j + \omega_1'; \omega_1', \omega_2') + \varphi(y_i + y_j + \omega_1'; \omega_1', \omega_2') \right] + c_l \sum_{i=1}^r \varphi(2y_i; \omega_1', \omega_2'). \]

(2.4)

We have chosen a standard parameterisation of the vector \( X \) as well as the root systems, and we have assigned half-periods \( \omega_j \) to the \( B \)-system and \( \omega_j' \) to the \( C \)-system. We have also made explicit the twisted Weierstrass functions \( \wp \) with twisting index 2, which is the ratio of lengths squared of the long and short roots. To demonstrate the duality between these models, we use the elliptic function identities \( \text{[B.5]} \) to manipulate the \( so(2r+1) \) potential such that it becomes of the form of the \( sp(2r) \) potential:

\[ V_B = b_l \left[ \sum_{i<j} \varphi(x_i - x_j; 2\omega_2, -\omega_1) + \varphi(x_i - x_j + 2\omega_2; 2\omega_2, -\omega_1) + \varphi(x_i + x_j; 2\omega_2, -\omega_1) + \varphi(x_i + x_j + 2\omega_2; 2\omega_2, -\omega_1) \right] + \frac{\pi^2 r (r-1)}{24 \omega_2^2} b_l \left[ 2E_2 \left( \frac{-\omega_1}{\omega_2} \right) - E_2 \left( \frac{-\omega_1}{2\omega_2} \right) \right] + \frac{\pi^2 r}{6\omega_1} b_s \left[ 2E_2 \left( \frac{\omega_2}{\omega_1} \right) - E_2 \left( \frac{\omega_2}{2\omega_1} \right) \right] = b_l \left[ \sum_{i<j} \varphi(x_i - x_j; 2\omega_2, -\omega_1) + \varphi(x_i - x_j + 2\omega_2; 2\omega_2, -\omega_1) + \varphi(x_i + x_j; 2\omega_2, -\omega_1) + \varphi(x_i + x_j + 2\omega_2; 2\omega_2, -\omega_1) \right] + \frac{\pi^2}{12\omega_1} (2r b_s + r(r-1) b_l) \left[ 2E_2 \left( \frac{\omega_2}{\omega_1} \right) - E_2 \left( \frac{\omega_2}{2\omega_1} \right) \right]. \]

(2.5)

In the last equality, we used the modular transformation rule \( \text{[C.3]} \) for a combination of second Eisenstein series. We observe that the end result \( \text{[2.5]} \) can be identified with the \( C_r \) potential \( \text{[2.4]} \), provided we

\[ \text{[For the non-simply laced cases, we will always work with the twisted model, and we will drop the corresponding subscript on the potential from now on.} \]
match parameters as follows:

$$
\omega'_1 = 2\omega_2 \quad \omega'_2 = -\omega_1 \quad y_i = x_i \\
c_s = b_i \quad c_t = 4b_s,
$$

and we allow for a $\tau$-dependent shift of the potential that invokes the second Eisenstein series $E_2$. These identifications imply a duality (which we will denote $S_2$) between the modular parameters of the $B$ and $C$-type integrable systems:

$$
\tau^B \equiv -\frac{1}{2\tau C}.
$$

In the following, we will be interested in $B$ and $C$ models in which the ratio of the long to short root coupling constants is equal to two, i.e. we put $b_l = b = 2b_s$ and $c_l = c = 2c_s$. It is important that this relation is compatible with the duality map \([2.6]\). We summarise the identity of the potentials for this specific ratio of parameters:

$$
\sum_{i<j} \varphi(x_i - x_j; \omega_1, \omega_2) + \frac{1}{2} \left( \sum_i \varphi(x_i; \omega_1, \omega_2) + \varphi(x_1 + \omega_1; \omega_1, \omega_2) \right) = \\
\sum_{i<j} \varphi(x_i - x_j; 2\omega_2, -\omega_1) + \varphi(x_i - x_j + 2\omega_2, 2\omega_2, -\omega_1) + \varphi(x_i + x_j; 2\omega_2, -\omega_1) + \\
\varphi(x_1 + \omega_1; 2\omega_2, -\omega_1) + 2 \sum_i \varphi(2x_i; 2\omega_2, -\omega_1) + \frac{\pi^2 r^2}{12\omega^2} \left[ 2E_2 \left( \frac{2\omega_2}{\omega_1} \right) - E_2 \left( \frac{\omega_2}{\omega_1} \right) \right],
$$

and the integrable system duality can be summarised as:

$$
V_B(x_1, \tau) = \frac{1}{2\tau^2} V_C \left( \frac{x_1}{2\tau}, -\frac{1}{2\tau} \right) + \frac{\pi^2 r^2}{3\omega^2} \left[ 2E_2(2\tau) - E_2(\tau) \right],
$$

when we use the rescaling \([B.2]\). The duality may be viewed as a standard Langlands duality. We went through its detailed derivation since the $\tau$-dependent shift in the duality transformation \([2.8]\) is important for later purposes.

### 2.2.1 Langlands duality at rank two

There is a further special case of low rank which is of particular interest to us in the following. The $B$ and $C$ type Lie algebras of rank two are identical: $so(5) \equiv sp(4)$. If we apply the duality of $B$ and $C$ type potentials to this special case, we derive that the following transformations leave the potential invariant:

$$
\omega'_1 = 2\omega_2 \quad \omega'_2 = -\omega_1 \quad c' = 2b \\
x'_2 - x'_1 = 2x_1 \quad x'_1 + x'_2 = 2x_2.
$$

If we parameterise the potential in terms of the modular parameter $\tau = \omega_2/\omega_1$, the duality transformation for $so(5)$ reads:

$$
V_{so(5)}(x_1, x_2, \tau) = \frac{1}{2\tau^2} V_{so(5)} \left( \frac{x_1 + x_2}{2\tau}, \frac{x_1 - x_2}{2\tau}, -\frac{1}{2\tau} \right) + \frac{4\pi^2}{3} \left[ 2E_2(2\tau) - E_2(\tau) \right].
$$

In summary, we derived a Langlands duality between $B$ and $C$ type (twisted) elliptic Calogero-Moser models. The resulting identities captured in equations \([2.8]\) and \([2.10]\) and the shifts appearing in these duality transformations will be useful. We return to the more general discussion of the integrable systems, and in particular their extrema.

### 2.3 Integrable Models at Extrema

There have been many studies of classical integrable models at equilibrium. These have uncovered remarkable properties, like the integrality of the minimum of the potential and of the frequencies of small oscillations around the minimum, amongst others (see e.g. \([15, 16, 17]\)). We will analyse the potential of certain elliptic integrable systems evaluated at generalised equilibrium positions. We show that they give rise to interesting vector valued modular forms as well as more general non-analytic modular vectors. Modularity provides a more conceptual way of understanding the integrality properties of the integrable

---

Footnote: Various particular choices of parameters and observables that we make in section 2 are motivated by the gauge theory applications that we will discuss in section 3. It is also of interest to study the integrable systems more generally.
system. This rationale then continues to hold for the integrable systems that can be obtained from the elliptic Calogero-Moser systems by limiting procedures (e.g. the trigonometric models). Thus, studying elliptic integrable systems, depending on a modular parameter, is found to have an additional pay-off.

It is known that $A$-type integrable systems often have simpler properties than do the integrable systems associated with other root systems. As a relevant example, let us quote the fact that the (real) Calogero-Moser (Sutherland) system with trigonometric potential of $A$-type has equally spaced equilibrium positions along the real axis, while the $B, C, D$-type potentials have minima associated to zeroes of Jacobi polynomials [10], which satisfy known relations [23], but are not known explicitly in general. The elliptic Calogero-Moser systems that we examine show a similar dichotomy. Extrema of the (complex) elliptic $A$-model are equally spaced. This fact leads to relatively easily constructable values for the potential at extrema, for any rank [5, 12, 24]. For the $B, C, D$-type models that we study in this paper, much less is known, and we need to combine numerical searches with analytic approaches to determine the extremal values of the potential, for low rank cases.

To be more precise, we will be interested in extrema of the complexified potential, satisfying:

$$\partial_{X_j} V(X_j) = 0 \quad \forall i,$$

and we moreover demand that at the extremum the function

$$\sum_{i=1}^{r} |\partial_{X_i} V(X_i)|^2$$

not possess any flat directions.$^5$

We will consider extrema that are related by the action of the Weyl group of the Lie algebra to be equivalent. The periodicity in the $\omega_i$ direction will be given by the weight lattice, while in the $\omega_2$ direction it is the co-weight lattice.$^7$ Outer automorphism groups on the other hand are taken to be global symmetries of the problem – the global symmetries relate degenerate extrema when broken.

### 2.4 The Case $A_r = su(r+1)$

The extrema of the elliptic Calogero-Moser model of type $A_r$ have been studied in great detail, mostly in the context of supersymmetric gauge theory dynamics (see e.g. [5, 12, 24]). Firstly, we remark that in this case, the equivalence relations that follow from the periodicity of the potential as well as the Weyl symmetry group of the Lie algebra are straightforwardly implemented. We use the parameterisation of simple roots in terms of orthogonal vectors $\alpha_i = e_i - e_{i+1}$, and the fundamental weights then read $\pi_i = \sum_{j=1}^r e_j$, with weight lattice spanned by the vectors $e_i$. We can parameterise the coordinates of our integrable system by a vector $X_j e_j$ living in the dual to the root space (and $e_j (e_j) = \delta_{ij}$). The Weyl group $S_n$ acts by permuting the components $X_j$. We can shift one of the components $X_j$ to zero by convention. The equivalence under shifts by fundamental weights is identical to the toroidal periodicity relations for the individual coordinates $X_j$. The inequivalent extrema of the $su(n)$ potential (satisfying the additional condition of non-flatness) are then argued to correspond one-to-one to sublattices of order $n$ of the torus with modular parameter $\tau$ [5, 12]. These extrema are classified by two integers $p$ and $k$ satisfying that $p$ is a divisor of $n$ and $k \in \{0, 1, \ldots, \frac{n}{p} - 1\}$. The number of extrema is equal to the sum of the divisors of $n$. The $\mathbb{Z}_2$ outer automorphism of $A_{r>1}$ acts trivially on the minima, since it acts by permutation, combined with a sign flip for all $X_j$, which leaves a sublattice ankered at the origin invariant.

The value of the potential at one of these extrema is (with a given choice of coupling constant):

$$V_{A_{n-1}}(\tau) = \frac{n^3}{24} \left( E_2(\tau) - \frac{p}{q} E_2 \left( \frac{p}{q} \tau + \frac{k}{q} \right) \right),$$

Under the $SL(2, \mathbb{Z})$ action on the torus modular parameter $\tau$, the sublattices of order $n$ of the torus are permuted into each other (in a way that depends intricately on the integer $n$). The permutation of the sublattices also entails the permutation of the values at these extrema under $SL(2, \mathbb{Z})$. The list of extremal values of the elliptic Calogero-Moser model therefore form a vector valued modular form (see e.g. [25, 26, 27]) of weight two under the group $SL(2, \mathbb{Z})$. The associated representation of the modular group is a representation in terms of permutations specified by the $SL(2, \mathbb{Z})$ action on sublattices of order

---

$^5$This will correspond, in section 3, to a supersymmetric vacuum in the $\mathcal{N} = 1^*$ gauge theory, where the effective superpotential $W$ is identified with the potential $V$ of the integrable system.

$^6$This condition implies that the vacuum is massive in the supersymmetric gauge theory. We briefly comment on massless vacua later on.

$^7$We will take the length squared of long roots to be equal to two. A co-weight $\lambda^\vee$ satisfies $\langle \alpha, \lambda^\vee \rangle \in \mathbb{Z}$ for all roots $\alpha$. See appendix for further details.
One can identify a subgroup of the modular group under which a given component of the vector-valued modular form is invariant, and then use minimal data to fix it.

In summary, the extrema of the Calogero-Moser model of type $A_r = su(r+1)$ are under analytic control. The positioning of the extrema can be expressed linearly in terms of the periods of the model, and the vector valued modular form of extremal values for the potential has an automorphy factor that can be characterised by sublattice permutation properties. The extremal values are generalised Eisenstein series of weight two under congruence subgroups of the modular group.

### 2.5 The $B, C, D$ Models

For other algebras, we are at the moment only able to study low rank cases. From the analysis, it is clear that crucial simplifying properties of the $A_r$ case are absent. Nevertheless, generic features of the $A_r$ case persist in a subclass of extrema, in that we find vector-valued modular forms as extremal values for the potential. We also find a class of extremal values that exhibit new features.

To describe in detail which extrema are considered to be equivalent, we must discuss the equivalence relations that we mod out by for the $B, C$ and $D$ root systems individually.

$D_r = so(2r)$

For the $D_r$ case, we can parameterise the roots as $\alpha_i = e_i - e_{i+1} \ (\text{for } i \in \{1, 2, \ldots, r-1\})$ and $\alpha_r = e_r$. We put $X = X_1 e^j$ and imply that the relation $e_j(e^j) = \delta^j_i$ holds. The equivalence of the vector $X$ under shifts proportional to the weight lattice implies that each variable $X_j$ lives on a torus with modular parameter $\tau$. It moreover identifies the vector $X$ with the vector $X$ shifted by a half-period in each variable simultaneously. The Weyl group is $W(so(2r)) = S_r \ltimes \mathbb{Z}_{2(r-1)}^r$, and acts by permutation of the components $X_j$, as well as the sign change of an even number of them. The outer automorphism group (for $r \neq 4$) is equal to $\mathbb{Z}_2$ and acts as $X_r \to -X_r$. For $r = 4$, the global symmetry group is $S_3$ triality.

$B_r = so(2r + 1)$

For $B_r$, the roots are $\alpha_i = e_i - e_{i+1} \ (\text{for } i \in \{1, 2, \ldots, r-1\})$ and $\alpha_r = e_r$. We recall that the periodicity is the weight lattice in the $\omega_1$ direction (due to the twist), and the co-weight lattice in the $\omega_2$ direction. Thus, we can shift components of the vector $X = X_1 e^j$ by periods, or all components simultaneously by a half period in the $\omega_1$ direction. In the $\omega_2$ direction, we allow shifts of the individual components by periods. The Weyl group acts by combinations of permutations and any sign flip of the coordinates.

$C_r = sp(2r)$

The roots are $\alpha_i = (e_i - e_{i+1})/\sqrt{2} \ (\text{for } i \in \{1, 2, \ldots, r-1\})$ and $\alpha_r = \sqrt{2} e_r$.

We can shift components $X_j$ of $X = \sqrt{2} X_1 e^j$ by half-periods in the $\omega_1$ direction, while in the $\omega_2$ direction, we can allow shifts by any period, as well as a half-period shift of all $X_j$ simultaneously. The Weyl group allows any permutation and sign flip of the coordinates. The equivalence relations and symmetries in the $B, C$ and $D$ cases, beyond permutation symmetries and toroidal periodicity, are summarized in the table:

|    | $B_r$ | $C_r$ | $D_r$ |
|----|-------|-------|-------|
| Individual | $X_i \to -X_i$ | $X_i \to X_i + \omega_1$ | Even number of sign flips | $X_i \to -X_i$ |
| Collective | $X_i \to X_i + \omega_1$ | $X_i \to X_i + \omega_2$ | Collective | $X_i \to X_i + \omega_1$ and $X_i \to X_i + \omega_2$ |
|     |       |       | Global symmetries: $\mathbb{Z}_2$ generically and $S_3$ for $D_4$. |

Armed with this detailed knowledge about the equivalence of configurations, we programmed a numerical search for isolated extrema. In the following subsections, we list the results we found by root system. For simply laced root systems we studied the elliptic Calogero-Moser model, while results for non-simply laced root systems correspond to the twisted elliptic Calogero-Moser model with a coefficient for the short root term which is equal to one half the coefficient in front of the long root terms (as described below equation [2.7]).

---

*By our conventions, we normalise the long roots such that they have length squared two.*
2.6 The Case $C_2 = sp(4) = so(5)$ and Vector Valued Modular Forms

Since the root system $C_2$ is the first example of our series, we provide a detailed discussion. We discuss the positions of the isolated extrema, the series expansions relevant to the potential at these extrema, the action of the duality group, as well as the identification of the relevant vector valued modular forms.

2.6.1 The positions of the extrema

For the Lie algebra $so(5) = sp(4)$ we found 7 isolated extrema of the potential. We provide their positioning at $\tau = i$ in the following figures. We have drawn in bold the positions of the extrema as well as their opposites, in a fundamental cell of the torus.\[9]

These numerical results were found using a Mathematica program, which was written around the built-in function FindMinimum. Careful programming augments the precision of the algorithm to at least \[8\]

*We have indicated reflections over other half-periods in grey, to illustrate that the minima are close to forming sublattice structures.*
two hundred digits. The most costly part of the algorithm is the random search for extrema. Indeed, the intricate landscape drawn by the potential can hide extrema. We gave a drawing of the position of the numbered extrema on the torus with modular parameter \( \tau = i \). The positions of the extrema for other values of the modular parameter can be reached by interpolation. We have analytic control over a few extra properties of the extrema. E.g. if we follow extremum 1 to \( \tau = i \infty \), we find that the equilibrium positions are given by \( \frac{1}{\pi} \arccos(\pm 1/\sqrt{3}) \) where \( \pm 1/\sqrt{3} \) are the zeroes of the Jacobi polynomial \( P_2^{(0,0)} \). The first extremum, which we label 1, lies on the real axis and is the equilibrium position of the real integrable system. The extremum 2 lies on the imaginary axis, while extrema 3 and 4 are \( S_2 \) Langlands duals of extrema 3 and 4. It is easy to deduce from the potential that the positions of the extrema generically behave non-linearly as a function of \( \tau \).

### 2.6.2 Series expansions of the extrema

By numerically evaluating the extrema of the potential for a range of values of the modular parameter \( \tau \), we are able to write the extrema as an expansion in terms of a power of the modular parameter \( q = e^{2\pi i \tau} \). The extremal values can be written in terms of the series:

\[
\begin{align*}
A_0(q) &= \frac{1}{24} + q + q^2 + 4q^3 + q^4 + 6q^5 + 4q^6 + 8q^7 + q^8 + 13q^9 + 6q^{10} + 12q^{11} \\
&\quad + 4q^{12} + 14q^{13} + 8q^{14} + \ldots \\
A_1(q) &= 1 + 48q + 828q^2 + 1086q^3 + 109890q^4 + 1451520q^5 + 11198088q^6 + 141212160q^7 \\
&\quad + 1666682811q^8 + 9413050176q^9 + 14502226892q^{10} + 1838450006784q^{11} \\
&\quad + 130394590326q^{12} + 138638111404032q^{13} + \ldots \\
A_2(q) &= 2 + 48q + 576q^2 + 9792q^3 + 95976q^4 + 13146624q^5 + 11573984q^6 \\
&\quad + 101572736q^7 + 143384424q^8 + 100250482176q^9 + 935515738944q^{10} \\
&\quad + 12532363069968q^{11} + 122390111901744q^{13} + \ldots \\
A_3(q) &= \frac{13}{216} + 7q + 541q^2 + 24508q^3 + 939669q^4 + 19944842q^5 + 764752180q^6 \\
&\quad + 21016537080q^7 + 905672825157q^8 + 38827071780859q^9 + 827503353279726q^{10} + \ldots \\
A_4(q) &= 1 + 148q + 7446q^2 + 154344q^3 + 5100349q^4 + 352720380q^5 + 10627587582q^6 \\
&\quad + 1661241848889q^7 + 5419843397586q^8 + 294399334337124q^9 + \ldots \\
A_5(q) &= -\frac{1}{216} + 29q + 431q^2 + 80468q^3 - 231081q^4 + 94846144q^5 + 1301490428q^6 \\
&\quad + 90560563752q^7 - 529100109649q^8 + 93349951292249q^9 + \ldots .
\end{align*}
\]

The integer coefficients have been determined up to an accuracy of at least \( 10^{-6} \). For the first order terms, the accuracy can be up to \( 10^{-200} \). In terms of these series, the potential in extremum number 1, on the real axis is (with a given choice of normalisation):

\[
V_1 = 144\pi^2 A_3 \left( \frac{q}{27} \right).
\]

The potential in the other extrema are:

\[
\begin{align*}
V_2 &= -12\pi^2 \left( \frac{8}{3} A_0(q) + (2q)^{1/3} A_1(q/9) + (2q)^{2/3} A_2(q/9) \right) \\
V_3 &= -12\pi^2 \left( \frac{8}{3} A_0(q) + (2q)^{1/3} e^{2\pi i/3} A_1(q/9) + (2q)^{2/3} e^{4\pi i/3} A_2(q/9) \right) \\
V_4 &= -12\pi^2 \left( \frac{8}{3} A_0(q) + (2q)^{1/3} e^{4\pi i/3} A_1(q/9) + (2q)^{2/3} e^{2\pi i/3} A_2(q/9) \right),
\end{align*}
\]

and

\[
\begin{align*}
V_{5,6} &= 72\pi^2 \left( A_5 \left( \frac{q}{27} \right) \pm i \sqrt{\frac{q}{27}} A_4 \left( -\frac{q}{27} \right) \right) \\
V_7 &= \frac{48}{3} \pi^2 A_0(q).
\end{align*}
\]

The growth properties of these series, as well as the fact that we are dealing with a physical system living on a torus suggests turning these numerical data into an analytic understanding, based on the theory of modular forms. In the following, we show that this is possible for the rank 2 root system \( B_2 \).
Figure 1: The diagram of the action of dualities on the extrema for $B_2 = so(5)$. In red, we draw the action of Langlands $S_2$-duality, and in green, $T$-duality (when the action is non-trivial).

2.6.3 The extrema as modular forms of the Hecke group and the $\Gamma_0(4)$ subgroup

We need to introduce a few groups related to the modular group. We already noted the duality transform for the $B, C$-type twisted Calogero-Moser system under the map $S_2 : \tau \rightarrow -1/(2\tau)$ (see equation (2.7)). For the $so(5)$ Lie algebra, which is identical to the $sp(4)$ Lie algebra, this transformation maps the integrable system to itself (up to a $\tau$ dependent shift of the potential and an overall factor – see equation (2.10)). The map $T : \tau \rightarrow \tau + 1$ also maps the integrable system to itself. Together, these transformations generate the action of a Hecke group dubbed $\Gamma^*(2)$ on the modular parameter $\tau$. This group contains a subgroup $\Gamma_0(4)$ which is a congruence subgroup of the modular group $SL(2, \mathbb{Z})$. Generators of the group $\Gamma_0(4)$ can be chosen to be the $2 \times 2$ matrices:

$$T : \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad U : \begin{pmatrix} 1 & 0 \\ 4 & 1 \end{pmatrix}. \quad (2.19)$$

The action of these matrices on $\tau$ coincides with the action of the elements $T$ and $U = S_2 T^{-2} S_2$ of the Hecke group. For more information on Hecke groups and associated modular forms see e.g. the lectures [29].

The extremal values of the potential may therefore form a vector valued modular form with respect to the Hecke group $\Gamma^*(2)$, and as a consequence also with respect to the congruence subgroup $\Gamma_0(4)$ of the modular group $SL(2, \mathbb{Z})$, since we expect extrema to be at most permuted and/or rescaled under the group. Here, we assume analyticity in the interior of the fundamental domain. We will mostly exploit the group $\Gamma_0(4)$ in the following, since the literature on the subject of modular forms with respect to congruence subgroups is abundant. For starters, we determine the action of the operations $T$ and $S_2$ on the vector $V_i$ of extremal values of the twisted Calogero-Moser potential:

$$T : \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$S_2 : \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & -2 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -2 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \end{pmatrix}. \quad (2.20)$$

See figure [1] for a summary of the action of the duality group. To this information, we add the last column in the matrix $S_2$, which originates in the shift of the potential under Langlands duality. From these data, we easily calculate the action of the generator $U = S_2 T^{-2} S_2$ on the vector valued modular form:

$$U : \begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \quad (2.21)$$
We find the action of $\Gamma_0(4)$ on the vector valued modular form, and we observe the following pattern: there is one entry (the seventh) which is an ordinary modular form of weight 2 under $\Gamma_0(4)$, and there are two sets of three components (namely $\{2, 3, 4\}$ and $\{1, 5, 6\}$) that mix under $\Gamma_0(4)$. Concentrating on the ordinary modular form of weight 2, we have that it is a linear combination of Eisenstein series $E_{2,N}$ defined by:

$$E_{2,N}(\tau) = E_2(\tau) - NE_2(N\tau).$$

(2.22)

Indeed, the dimension of the space $\mathcal{M}_2(\Gamma_0(4))$ of modular forms of $\Gamma_0(4)$ is two, and it is spanned by $E_{2,2}$ and $E_{2,4}$. We thus only need two Fourier coefficients to fix the entire modular form, and we find that:

$$A_0(q) = -\frac{1}{24}E_{2,2}(\tau) = \frac{1}{48}(\theta_4^4 + \theta_4^2)(\tau)$$

(2.23)

$$V_{\tau} = \frac{\pi^2}{3}(\theta_4^3 + \theta_4^1)(\tau).$$

(2.24)

We then have a slew of consistency checks on all the other integers that we determined numerically (see (2.14)). These thirteen checks work out. We do therefore claim that the result (2.24) is exact. This is a simple example illustrating our methodology.

Next, we consider the triplet consisting of the components $\{2, 3, 4\}$. We find three eigenvectors of $T$, with eigenvalues corresponding to the cubic roots of unity. The eigenvector with eigenvalue 1 is also mapped to itself under the $U$ transformation, and forms again a modular form of weight 2 under $\Gamma_0(4)$. It is indeed proportional to $E_{2,2}$:

$$V_2 + V_3 + V_4 = -2\pi^2(\theta_3^3 + \theta_1^3)(\tau).$$

(2.25)

The other two eigenvectors, we raise to the power three, such that they become invariant under the $T$-transformation. These forms belong to the space $\mathcal{M}_6(\Gamma_0(4))$ of weight six modular forms. The dimension of this vector space is 4 (see theorem 3.5.1 in [30] with $g = \varepsilon_2 = \varepsilon_3 = 0$ and $\varepsilon_\infty = 3$), and it consists of three Eisenstein series, and one cusp form. A basis for these vector spaces is given by:

$$E_6^1 = -\frac{1}{252}E_6(\tau)$$

(2.26)

$$E_6^2 = -\frac{1}{252}E_6(2\tau)$$

(2.27)

$$E_6^3 = -\frac{1}{252}E_6(4\tau)$$

(2.28)

$$S_6 = \eta(q^3)^{12},$$

(2.29)

where $E_6$ is the Eisenstein series of weight six, and $\eta$ is the $\eta$-function, also recorded in appendix C. We need four coefficients to fix the eigenvectors in terms of this basis and we find (using the notation $\omega_3 = \exp(2\pi i/3)$):

$$(V_2 + \omega_3V_3 + \omega_3^2V_4)^3 = -23328\pi^6(E_6^1 - E_6^2 - 2S_6)$$

(2.30)

$$(V_2 + \omega_3^2V_3 + \omega_3V_4)^3 = -23328\pi^6(E_6^1 - E_6^2 + 2S_6).$$

(2.31)

The consistency checks using the numerics work out.

For the second triplet, we diagonalise $U$ first, and proceed very analogously as above, except that we have to take a higher power for the second combination to find a modular form of weight 12 with respect to $\Gamma_0(4)$. We find the relations:

$$(V_1 + \omega_3V_5 + \omega_3^2V_6)^3 + (V_1 + \omega_3^2V_5 + \omega_3V_6)^3 = 5832\pi^6(E_6^1(q) - 64E_6^2)$$

$$(V_1 + \omega_3V_5 + \omega_3^2V_6)^3 - (V_1 + \omega_3^2V_5 + \omega_3V_6)^3)^2 = 136048896\pi^{12}\eta(q)^{24}.$$
Summary

In summary, we have full analytic control over the value of the potential for all isolated extrema of the so(5) twisted Calogero-Moser integrable system. We have found a vector valued modular form of weight two of $\Gamma_0(4)$, and we were able to explicitly express its seven components in terms of ordinary modular forms of $\Gamma_0(4)$. The plot will thicken at higher rank.

2.7 The Case $D_4 = so(8)$ and the Point of Monodromy

At this stage, we choose to present our results on the rank four $D_4 = so(8)$ model first, since they are simpler than those on the non-trivial rank three cases to be presented in subsection 2.8. The $so(8)$ model is simply laced and we therefore expect the ordinary modular group $SL(2, \mathbb{Z})$ to play the leading role. The integrable system exhibits a global symmetry group $S_3$ that permutes the three satellite simple roots of the Dynkin diagram of $so(8)$. We will refer to the $S_3$ permutation group as triality. We turn to the enumeration and classification of the extrema of the potential. We found 34 extrema. These are listed in the following paragraphs.

2.7.1 The singlet

There is a singlet under $S$ and $T$ duality as well as triality. It has zero potential: $V_1 = 0$.

2.7.2 The triplet

There is also a triplet under the duality group, labelled $\{2, 3, 4\}$, and the dualities act as:

$$T = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad S = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}. $$

The relations $S^2 = 1$ and $(ST)^3 = 1$ are satisfied. We note that in these extrema, the positions belong to the lattice generated by $\omega_1/2$ and $\omega_3/2$. For this multiplet, T-duality acts geometrically.

We would like to deduce again from the $S$ and $T$ matrices and from the known first coefficients of the series expansions (see appendix D.1) the exact expressions of the potentials in these extrema. The functions are expected to transform well under some congruence subgroup of the modular group. Note that the sum of the three functions must be a full-fledged modular form – indeed, the sum $V_2(q) + V_3(q) + V_4(q)$ vanishes. A brute force strategy leading to the identification of the appropriate congruence subgroup is the following. We decompose the generators of congruence subgroups in terms of a product of $S$ and $T$ operations. We evaluate the product using the representation at hand (here $3 \times 3$ matrices) and check whether it is trivial for every generator.

It turns out that the subgroup $\Gamma(2)$ acts trivially on the extremal potentials. Hence all the potentials $V_2$, $V_3$ and $V_4$ belong to $M_2(\Gamma(2))$. This space has dimension 2, and it is the set of linear combinations of the three Eisenstein functions associated to the three vectors of order 2 in $(\mathbb{Z}_2)^3$ which have the property that the sum of the three coefficients vanishes. (See appendix C for details and conventions). Matching a few coefficients, we find that

$$V_2 = 12 \left(2G_{2,2} \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} - G_{2,2} \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} - G_{2,2} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \right)$$

$$V_3 = 12 \left(-G_{2,2} \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} - G_{2,2} \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} + 2G_{2,2} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \right)$$

$$V_4 = 12 \left(-G_{2,2} \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} + 2G_{2,2} \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} - G_{2,2} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} \right).$$

This can also be written in terms of the Weierstrass $\wp$ function:

$$V_2(\tau) = 3 \left(2\wp \left(\frac{1}{2}; \tau \right) - \wp \left(\frac{\tau + 1}{2}; \tau \right) - \wp \left(\frac{\tau}{2}; \tau \right) \right)$$

$$V_3(\tau) = 3 \left(-\wp \left(\frac{1}{2}; \tau \right) - \wp \left(\frac{\tau + 1}{2}; \tau \right) + 2\wp \left(\frac{\tau}{2}; \tau \right) \right)$$

$$V_4(\tau) = 3 \left(-\wp \left(\frac{1}{2}; \tau \right) + 2\wp \left(\frac{\tau + 1}{2}; \tau \right) - \wp \left(\frac{\tau}{2}; \tau \right) \right).$$

10There exist algorithms to find the generators. These are for instance implemented in Sage.
These two ways of writing the potentials make the action of dualities manifest. For instance, the transformation properties (B.3) show that under $S$-duality, $\varphi(\frac{1}{2}, \tau)$ becomes $\varphi(\frac{1}{2}, \frac{1}{2}) = \tau^2 \varphi(\frac{1}{2}, \tau)$ while $\varphi(\frac{1}{2}, \tau)$ becomes $\tau^2 \varphi(\frac{1}{2}, \tau)$, so that $V_2$ and $V_3$ are $S$-dual, et cetera. The result can also be written using perhaps more familiar modular forms

$$V_2(q) = -6\pi^2 E_{2,2}(q)$$
$$V_3(q) = \frac{3}{2} \pi^2 \left( 2E_{2,2}(q) - 3\theta_2^4(q) \right)$$
$$V_4(q) = \frac{3}{2} \pi^2 \left( 2E_{2,2}(q) + 3\theta_2^4(q) \right).$$

The action of $T$-duality is again clear from these expressions. For $S$-duality it is slightly more intricate. Given that $E_{2,2}(q) = -\theta_2^4(q^2) - \theta_3^4(q^3)$, it relies on the identities

$$2\theta_2^4(2\tau) + 2\theta_3^4(2\tau) + 3\theta_4^4(\tau) = -\theta_2^4(\tau/2) + 2\theta_3^4(\tau/2)$$
$$\theta_3^4(\tau/2) + \theta_3^4(\tau/2) - 6\theta_4^4(\tau) = -4\theta_2^4(2\tau) - 4\theta_3^4(2\tau) + 6\theta_4^4(\tau),$$

for $S$-duality between extrema 2 and 3, and self-$S$-duality for extremum 4, respectively.

2.7.3 The quadruplet

We move on to discuss the extremal values of the potential in the quadruplet. We can arrive at the following closed form for the potential in extremum 6:

$$V_6(q) = -24\pi^2(-\frac{1}{24}E_{2,3}(q) + (q(q^3) + 9\eta(q^9)^3/\eta(q^3)/\eta(q) + 3(\eta(q^3)/\eta(q))^2).$$

Note that this can alternatively be written as

$$V_6(q) = -24\pi^2(g_0(q) + q^{1/3}g_1(q) + 3q^{2/3}g_2(q),$$

where the $g_i$ are functions that can be expanded into series with only integer powers of $q$ (and the three summands in this expression correspond to the same summands in the expression above). Thus we know how the operation $\tau \rightarrow \tau + 1$ acts on the extremum, and it generates two other extrema, whose potential we also know exactly. These are extrema 7 and 8:

$$V_7(q) = -24\pi^2(g_0(q) + e^{2i\pi/3}q^{1/3}g_1(q) + 3e^{-2i\pi/3}q^{2/3}g_2(q))$$
$$V_8(q) = -24\pi^2(g_0(q) + e^{-2i\pi/3}q^{1/3}g_1(q) + 3e^{2i\pi/3}q^{2/3}g_2(q)).$$

The potential for the extremum 5 is:

$$V_5(q) = -3\pi^2E_{2,3}(q).$$

In the basis $\{5, 6, 7, 8\}$ the matrices for $S$- and $T$-dualities are:

$$T = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix} \quad S = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}. $$

We can also apply the same method as above. The generators of $\Gamma(3)$ are all trivial in this basis. Thus the potentials are weight 2 modular forms of this congruence subgroup. The latter form a 3-dimensional space, generated by the zero-sum linear combinations of the 4 Eisenstein series associated to the order 3 vectors in $(\mathbb{Z}_3)^2$ (there are 8 such vectors, but the Eisenstein series are invariant under $v \rightarrow -v$, leaving only 4 distinct functions, see appendix). We find

$$V_5 = \frac{27}{2} \begin{pmatrix} 3G_{2,3} \begin{pmatrix} 0 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 0 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 2 \end{pmatrix} \end{pmatrix},$$

$$V_6 = \frac{27}{2} \begin{pmatrix} -G_{2,3} \begin{pmatrix} 0 \\ 1 \end{pmatrix} + 3G_{2,3} \begin{pmatrix} 1 \\ 0 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 2 \end{pmatrix} \end{pmatrix},$$

$$V_7 = \frac{27}{2} \begin{pmatrix} -G_{2,3} \begin{pmatrix} 0 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 0 \end{pmatrix} + 3G_{2,3} \begin{pmatrix} 1 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 2 \end{pmatrix} \end{pmatrix},$$

$$V_8 = \frac{27}{2} \begin{pmatrix} -G_{2,3} \begin{pmatrix} 0 \\ 1 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 0 \end{pmatrix} - G_{2,3} \begin{pmatrix} 1 \\ 1 \end{pmatrix} + 3G_{2,3} \begin{pmatrix} 1 \\ 2 \end{pmatrix} \end{pmatrix},$$
or alternatively,

\[
V_5(\tau) = \frac{3}{2} \left( 3\wp \left( \frac{1}{3}; \tau \right) - \wp \left( \frac{\tau + 1}{3}; \tau \right) - \wp \left( \frac{\tau + 2}{3}; \tau \right) \right) - \wp \left( \frac{\tau - 1}{3}; \tau \right) - \wp \left( \frac{\tau - 2}{3}; \tau \right) - \wp \left( \frac{\tau - 3}{3}; \tau \right) - \wp \left( \frac{\tau - 4}{3}; \tau \right) - \wp \left( \frac{\tau - 5}{3}; \tau \right) - \wp \left( \frac{\tau - 6}{3}; \tau \right) - \wp \left( \frac{\tau - 7}{3}; \tau \right) - \wp \left( \frac{\tau - 8}{3}; \tau \right) - \wp \left( \frac{\tau - 9}{3}; \tau \right) - \wp \left( \frac{\tau - 10}{3}; \tau \right) - \wp \left( \frac{\tau - 11}{3}; \tau \right) - \wp \left( \frac{\tau - 12}{3}; \tau \right)
\]

\[
V_6(\tau) = \frac{3}{2} \left( -\wp \left( \frac{1}{3}; \tau \right) + 3\wp \left( \frac{\tau + 1}{3}; \tau \right) - \wp \left( \frac{\tau + 2}{3}; \tau \right) \right) - \wp \left( \frac{\tau - 1}{3}; \tau \right) + 3\wp \left( \frac{\tau + 3}{3}; \tau \right) - \wp \left( \frac{\tau + 4}{3}; \tau \right) - \wp \left( \frac{\tau + 5}{3}; \tau \right) - \wp \left( \frac{\tau + 6}{3}; \tau \right) - \wp \left( \frac{\tau + 7}{3}; \tau \right) - \wp \left( \frac{\tau + 8}{3}; \tau \right) - \wp \left( \frac{\tau + 9}{3}; \tau \right) - \wp \left( \frac{\tau + 10}{3}; \tau \right) - \wp \left( \frac{\tau + 11}{3}; \tau \right) - \wp \left( \frac{\tau + 12}{3}; \tau \right)
\]

\[
V_7(\tau) = \frac{3}{2} \left( -\wp \left( \frac{1}{3}; \tau \right) - \wp \left( \frac{\tau + 1}{3}; \tau \right) + 3\wp \left( \frac{\tau + 2}{3}; \tau \right) \right) - \wp \left( \frac{\tau - 1}{3}; \tau \right) - \wp \left( \frac{\tau + 3}{3}; \tau \right) + 3\wp \left( \frac{\tau + 4}{3}; \tau \right) - \wp \left( \frac{\tau + 5}{3}; \tau \right) - \wp \left( \frac{\tau + 6}{3}; \tau \right) - \wp \left( \frac{\tau + 7}{3}; \tau \right) - \wp \left( \frac{\tau + 8}{3}; \tau \right) - \wp \left( \frac{\tau + 9}{3}; \tau \right) - \wp \left( \frac{\tau + 10}{3}; \tau \right) - \wp \left( \frac{\tau + 11}{3}; \tau \right) - \wp \left( \frac{\tau + 12}{3}; \tau \right)
\]

\[
V_8(\tau) = \frac{3}{2} \left( -\wp \left( \frac{1}{3}; \tau \right) - \wp \left( \frac{\tau + 1}{3}; \tau \right) - \wp \left( \frac{\tau + 2}{3}; \tau \right) \right) - \wp \left( \frac{\tau - 1}{3}; \tau \right) + 3\wp \left( \frac{\tau + 3}{3}; \tau \right) - \wp \left( \frac{\tau + 4}{3}; \tau \right) + 3\wp \left( \frac{\tau + 5}{3}; \tau \right) - \wp \left( \frac{\tau + 6}{3}; \tau \right) - \wp \left( \frac{\tau + 7}{3}; \tau \right) - \wp \left( \frac{\tau + 8}{3}; \tau \right) - \wp \left( \frac{\tau + 9}{3}; \tau \right) - \wp \left( \frac{\tau + 10}{3}; \tau \right) - \wp \left( \frac{\tau + 11}{3}; \tau \right) - \wp \left( \frac{\tau + 12}{3}; \tau \right)
\]

The dualities act on the vectors characterising the modular forms as follows

\[
T : \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} \rightarrow \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix},
\]

\[
S : \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} \leftrightarrow \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix}.
\]

This reproduces the action of the dualities on the associated extrema. Thus, while the pattern of the positions of the extrema is non-linear, the arguments of the values of the potential at certain extrema do provide a linear realisation of the duality group.

Finally, we note that triality generates three copies of the triplet as well as of the quadruplet. Indeed, each of these extrema is left invariant by a \( \mathbb{Z}_2 \) subgroup of \( S_3 \) (as described in appendix D.1).

Up to now, we have discussed the singlet, triplet and quadruplet whose duality diagrams are summarised in figure 2.

### 2.7.4 The duodecuplet and a point of monodromy

In the multiplet of size twelve, also depicted in figure 2, a new feature appears. We find that the extrema exhibit a monodromy around a point in the interior of the fundamental domain of the parameter \( \tau \). Thus, to be able to describe the multiplet structure in this case we must first discuss the monodromy.

#### The point of monodromy

We find a single point in the interior of the fundamental domain around which there is monodromy amongst extrema. It is possible to determine this point numerically\(^{11}\) and its value is close to \( \tau_M \approx 2.41558i \). In particular, the extrema 13 and 16 are exchanged when we follow a loop in the \( \tau \)-plane that closely circles the value \( \tau_M \). Moreover, using the geometry of the positions of the extrema 13 and 16, one can show that \( \tau_M \) is a solution of the system of equations

\[
\begin{align*}
\wp(z; \tau)^2 + \wp(z - \omega_3; \tau)^2 + \wp(2z - \omega_3; \tau)^2 &= \frac{\pi^2}{3} E_4(\tau) \\
2\wp'(z; \tau) + 2\wp'(z - \omega_3; \tau) + \wp'(2z - \omega_3; \tau) &= 0,
\end{align*}
\]

where \( \omega_3 = \omega_1 + \omega_2 \), which gives the numerical result

\[
\tau_M = 2.415576987549484510777262081474158860468152563579077460...i.
\]

Using the large accuracy of the value of the point of monodromy \( \tau_M \), we find the corresponding rational Klein invariant (with the normalisation (C.1)):

\[
j(\tau_M) = \frac{488095744}{125} = 1728 \times \frac{7626496}{3375}.
\]

This can be considered as an exact statement – the uncertainty is as low as \( 10^{-200} \). Elliptic curves with rational Klein invariant have interesting arithmetic properties (see e.g. [30]).

---

\(^{11}\)The most immediate manifestation of the monodromy phenomenon can be seen as a symmetry breaking in the equilibrium positions for extrema 13 and 16 when moving on the imaginary axis across the point of monodromy \( \tau_M \) (which is purely imaginary). Below this critical value, as can be seen in the diagrams drawn at \( \tau = i \) (in appendix D.1), the two extrema are exchanged by the \( \mathbb{Z}_2 \) action \( X_i \leftrightarrow -X_i \), while above the critical value, they are both invariant with respect to this action. This makes it possible to determine \( 2.41557 \leq \text{Im}\tau_M \leq 2.41558 \).
The extended duality group

We can add the monodromy group to the set of generators $S$ and $T$ that act on our vector of extrema. The resulting diagram of dualities then becomes the one in figure 2. The generators satisfy the relations:

- $S^2 = M^2 = 1$ and $T^6 = 1$, while $(TM)^8 = 1$
- $SM = MS$
- $(MST)^3 = 1$.

Once we are underneath the point of monodromy in the canonical fundamental domain, the matrix $MT$ plays the role usually taken by the matrix $T$ in $SL(2, \mathbb{Z})$. In particular, relations like $(ST)^3 = 1$ implied by the geometry of the fundamental domain of the modular group take on the form $(SMT)^3 = 1$, et cetera. Triality leaves each extremum invariant.

In appendix D.1 we give terms in the Fourier expansion of the extremal values of the potential in the duodecuplet. We note that a consistency and exhaustivity check on all multiplets is provided by the fact that the sum of all extrema in a given multiplet of $SL(2, \mathbb{Z})$ has to be a weight 2 modular form. The check works out: the sum equals zero in each multiplet separately, as it must. An analytic understanding of the duodecuplet extrema remains desirable.

2.8 The Dual Cases $B_3 = \mathfrak{so}(7)$ and $C_3 = \mathfrak{sp}(6)$

2.8.1 Exact multiplets

For the twisted elliptic integrable models associated to the dual Lie algebra root systems $\mathfrak{so}(7)$ and $\mathfrak{sp}(6)$, we present our results succinctly. We have found 17 isolated extrema for each, and they are Langlands dual. We have therefore 34 extrema in total. We identified two quadruplets of the full duality group for which we found analytic expressions for the potential at the extrema. The list of the corresponding extrema is given in appendix D.2. We find the following duality properties and analytic values for the extremal values of the potential. The extrema labelled $\{1, 2\}$ have extremal values for the $\mathfrak{so}(7)$ potential equal to $V_1(\tau)$ and $V_2(\tau)$. From the diagram of dualities (figure 3), we read off that these extremal values...
are modular forms of $\Gamma_0(4)$ with weight 2. Moreover, Langlands duality then implies that $V_1(2\tau)$ and $V_2(2\tau)$ are also of that ilk. The space $M_2(\Gamma_0(4))$ of these weight 2 forms has the two generators

$$-E_{2,2}(\tau) = \theta_4^2(2\tau) + \theta_3^2(2\tau) = 1/2(\theta_3^4(\tau) + \theta_4^4(\tau))$$

$$-E_{2,4}(\tau) = 3\theta_4^4(2\tau) = 3/4(\theta_3^4(\tau) + \theta_4^4(\tau))^2.$$

In terms of the generators, the extrema are:

$$V_1(\tau) = \pi^2(-E_{2,2}(\tau) - 2E_{2,4}(\tau))$$
$$V_2(\tau) = \pi^2(-7E_{2,2}(\tau) + 2E_{2,4}(\tau))$$
$$V_{1,\tau}(2\tau) = \pi^2(+E_{2,2}(\tau) + 0E_{2,4}(\tau))$$
$$V_{2,\tau}(2\tau) = \pi^2(-2E_{2,2}(\tau) + 1E_{2,4}(\tau)).$$

For the other quadruplet under the full duality group, we have a similar story, with the happy ending:

$$V_3(2\tau) = \pi^2/6(-15E_{2,2}(\tau) + 7E_{2,4}(\tau))$$
$$V_4(2\tau) = \pi^2/6(+9E_{2,2}(\tau) - 1E_{2,4}(\tau))$$
$$V_{3,\tau}(\tau) = 8\pi^2/3(-3E_{2,2}(\tau) + 1E_{2,4}(\tau))$$
$$V_{4,\tau}(\tau) = 8\pi^2/3(0E_{2,2}(\tau) - 1E_{2,4}(\tau)).$$

The action of Langlands $S_2$ duality as well as T-duality can be found explicitly using these exact expressions, for instance by exploiting properties of $\theta$ functions. As an example, we note that the action of $T$-duality is summarised in the equalities:

$$E_{2,2} \left( \tau + \frac{1}{2} \right) = -2E_{2,2}(\tau) + E_{2,4}(\tau)$$
$$E_{2,4} \left( \tau + \frac{1}{2} \right) = -3E_{2,2}(\tau) + 2E_{2,4}(\tau).$$

Moreover, on the extrema, the Langlands duality $S_2$ acts as

$$\frac{1}{2\tau^2}V_1 \left( -\frac{1}{2\tau} \right) = V_{1,\tau}(\tau) + 3\pi^2E_{2,2}(\tau),$$

and similar relations hold for the other $S_2$-dual couples, as predicted by the duality formula (2.8).

### 2.8.2 The duodecuplet, the quattuordecuplet and the points of monodromy

We further identified a duodecuplet and a quattuordecuplet under the duality group (for a total of $(4 + 4 + 12 + 14)/2 = 17$ extrema for $B_3 = so(7)$). Sufficient data to reproduce them is provided in appendix D.2. These multiplets exhibit points of monodromy, and the full duality diagram is captured in figure 3. It should be understood that we only represent points of monodromy that are inequivalent (where two monodromies are taken to be equivalent when they are equal up to conjugation by other elements of the duality group). For instance $S_2M_2S_2$ is the monodromy around $-1/(2\tau)$.

We draw attention to a few features of the diagram. There are 5 extrema that form a quintuplet under T-duality (around $\tau = i\infty$), labelled 5, 6, 7, 8, 9. When we also turn around the point of monodromy, the quintuplet enhances to a septuplet. This is reminiscent of a feature of the duality diagram for the duodecuplet of $so(8)$.

Finally, we performed an exhaustivity check on the extrema by summing the extremal values of the potential. We found\(^\text{12}\)

$$\sum_{i\in4_1} V_i(\tau) = -8\pi^2E_{2,2}(\tau)$$
$$\sum_{i\in4_2} V_i(\tau) = 2\pi^2E_{2,2}(\tau)$$
$$\sum_{i\in12} V_i(\tau) = -20\pi^2E_{2,2}(\tau)$$
$$\sum_{i\in14} V_i(\tau) = 19\pi^2E_{2,2}(\tau),$$

\(^\text{12}\)We evaluated the sum of the extrema numerically at two different values of $\tau$ to identify the linear combination of $E_{2,2}$ and $E_{2,4}$ that equals the sum. We can then perform arbitrary many numerical checks at other values of $\tau$, and these work out.
Figure 3: The diagram of dualities for $so(7)$ and $sp(6)$ extrema. In red, we show the action of Langlands $S_2$-duality on the extrema, in green, $T$-duality, and in dotted blue, monodromies, with the corresponding approximate values of the points of monodromy $\tau$. As discussed in the text, monodromies relating $sp(6)$ extrema exist but are not represented here as they are equivalent to those already depicted.
This concludes our systematic case-by-case discussion of the low rank $B, C, D$ isolated extrema of (twisted) elliptic Calogero-Moser models. We finish the section with a few further remarks on general features of the problem of identifying isolated extrema.

2.9 Limiting Behaviour

We wish to make a remark on the limiting behaviour of the integrable models near an extremum. As an example, consider extremum number 7 for $B_2 = so(5)$ which has its extremal positions equal to a real number plus $\tau/2$. We can take the limit of the potential as $\tau \to i\infty$ while keeping the difference between the extremal positions and $\tau/2$ fixed. The limit of the integrable system is then a (trigonometric) Sutherland system of type $D_2 = so(4)$, and indeed, the real part of the extremal positions agrees with those of the Sutherland system. This is but one example of the limiting behaviour of the models near the extrema.

2.10 Partial Results for Other Lie Algebras

In this subsection, we discuss very partial results for some higher rank Lie algebras. We think of the elliptic integrable model as a perturbation of the Sutherland model, with trigonometric potential. The Sutherland model has a ground state with all particles sprinkled on the real circle. We can perturb this traditional ground state by turning on the elliptic deformation by powers of the small parameter $q$, and follow the ground state under perturbation. In this way, we can reconstruct the extremum of the complexified elliptic potential associated to the Sutherland extremum on the real line. To take the limit from the elliptic integrable system towards the Sutherland model, it is sufficient to use the expansion formula:

$$\varphi(x; \omega_1, \omega_2) = -\frac{\pi^2}{12\omega_1} E_2(q) + \frac{\pi^2}{4\omega_1^2} \csc^2\left(\frac{\pi x}{2\omega_1}\right) - \frac{2\pi^2}{\omega_1^2} \sum_{n=1}^{\infty} \frac{1}{1 - q^n} \cos \frac{n\pi x}{\omega_1},$$

valid when the imaginary part of the modular parameter $\tau$ is sufficiently large. The first term in the formula (2.34) is constant from the perspective of the integrable system dynamics, while the second term gives rise to the leading Sutherland potential. The minimum at the equilibrium of the Sutherland potential on the real line can be computed analytically [16] – it is related to the norm of the Weyl vector of the Lie algebra. The positions of the equilibria are given in terms of zeroes of the Jacobi polynomials.
Table 1: The integer $N$ for gauge algebra $so(k)$ rendering the Fourier expansion integral

We can perform perturbation theory around these extrema (numerically), and we find the following series in $q$ for the potential at perturbed Sutherland extrema, for various gauge algebras:

$$
\frac{V_{so(5)}}{\pi^2} = \frac{26}{3} + \frac{112q}{3} + \frac{8656q^2}{81} + \frac{392128q^3}{2187} + \frac{5011568q^4}{19683} + \frac{319117472q^5}{1594323} + \ldots
$$

$$
\frac{V_{so(6)}}{\pi^2} = 8 + 64q + 192q^2 + 256q^3 + 192q^4 + 384q^5 + 768q^6 + 512q^7 + 192q^8 + \ldots
$$

$$
\frac{V_{so(7)}}{\pi^2} = 25 + \frac{408q}{5} + \frac{153816q^2}{625} + \frac{23730528q^3}{78125} + \frac{6103562136q^4}{9765625} + \frac{66346128528q^5}{1220703125} + \ldots
$$

$$
\frac{V_{so(8)}}{\pi^2} = 24 + \frac{576q}{5} + \frac{212544q^2}{625} + \frac{3953944q^3}{78125} + \frac{6618263616q^4}{9765625} + \frac{90987162966q^5}{1220703125} + \ldots
$$

$$
\frac{V_{so(9)}}{\pi^2} = 164 + \frac{992q}{3} + \frac{5133728q^2}{12005} + \frac{2305844608q^3}{411715} + \frac{16890299438112q^4}{17654703625} + \ldots
$$

$$
\frac{V_{so(10)}}{\pi^2} = 169 + \frac{1280q}{3} + \frac{1330808q^2}{72405} + \frac{616518656q^3}{823543} + \frac{36560247552q^4}{282457249} + \frac{98689010407}{474561509943} + \frac{184012769746233876q^5}{390093429642968675} + \ldots
$$

$$
\frac{V_{so(11)}}{\pi^2} = 305 + \frac{1960q}{3} + \frac{30141880q^2}{45927} + \frac{29034410080q^3}{33480783} + \frac{424308824219480q^4}{2790589782267} + \frac{4158096750783162994374880q^5}{61030185318792792} + \ldots
$$

$$
\frac{V_{so(12)}}{\pi^2} = 100 + \frac{800q}{3} + \frac{4055200q^2}{5103} + \frac{1335048000q^3}{1240029} + \frac{34451725707}{63808646477600q^{4}} + \frac{4294503358692800q^5}{25115308040403} + \frac{633215756583464948800q^6}{209335859895594674} + \ldots
$$

We see that at least for some extrema, it is fairly straightforward to generate interesting data on the value of the potential at these extrema at higher rank. We note a first pattern, valid at the order to which we have worked, in both the rank of the gauge group, and the power of the modular parameter $q$. Table 1 gives the conjectured smallest integer $N$ such that for gauge algebra $g$, the potential $V_g(Nq)/\pi^2$ has a Fourier expansion with only integer coefficients in the following sense: the expansion can be written as $n_0(r + n_1q + n_2q^2 + \ldots)$ where the $n_i$ are integers, and the first term $r$ is rational. As an example of this pattern, let us quote the formula:

$$
\frac{1}{66679200\pi^2} V_{so(12)} (63^3 \times q) = \frac{1}{666792} + q + 745143q^2 + 252572301828q^3 + 10858373203688599q^4 + 250667695926903383446q^5 + 11087973944032043230752348q^6 + 196665218038741854168182867614728q^7 + \ldots
$$

As a final remark, we note that our numerical searches in this and previous subsections are far from exhausting the capabilities of present day computers.
3 The Massive Vacua of $\mathcal{N} = 1^*$ gauge theories

In this section, we first briefly review properties of the infrared physics of the $\mathcal{N} = 1^*$ supersymmetric gauge theory, and then show how the data we gathered on elliptic integrable systems in section 2 elucidates the physics of this gauge theory further. We obtain the $\mathcal{N} = 1^*$ gauge theory from $\mathcal{N} = 4$ supersymmetric Yang-Mills theory with gauge group $G$ by adding three masses $m_i$ for the three chiral $\mathcal{N} = 1$ supermultiplets. We can then go to the Coulomb branch of the gauge theory, and compactify the theory on a circle $\mathbb{I}$. Two massless scalars remain in the theory for each $U(1)$ in the unbroken $U(1)^r$ gauge group, namely the Wilson lines $\phi = \int_{S^1} A_\mu dx^\mu$ and the scalar duals $\sigma$ of the photons. Since there are no fields in the theory which are charged under the center of the gauge group, we may choose the gauge group such that we allow for gauge transformations that twist around the circle by an element of the center. This lends a periodicity to the Wilson line under shifts taking values in the co-weight lattice (namely, the dual to the root lattice). This reasoning corresponds to a choice of gauge group $G = \hat{G}/C$ where $\hat{G}$ is the universal cover, and $C$ its center. Other choices of gauge groups will not alter the local physics we describe, but are important in identifying spectra of line operators that can probe the phases of the theory \cite{5, 31, 32}. We concentrate on local physics in the following. The duals of the photons have a periodicity dual to the charge lattice of magnetic monopoles. Magnetic monopole charges take values in the dual root lattice, so the periodicity in the dual photon direction is given by the weight lattice of the gauge algebra.

We have identified the shift symmetries acting on the Wilson line and the dual photon. We further divide out configuration space by the Weyl group, which is the remnant of gauge invariance. We set up our discussion of the integrable system in such a way that the notion of equivalence used in section 2 precisely agrees with the present gauge theory analysis.

Our $\mathcal{N} = 1^*$ theory is a deformation of $\mathcal{N} = 4$ theory, and it inherits some of its properties. In particular, the electric-magnetic duality group of $\mathcal{N} = 4$ gauge theories in four dimensions \cite{33, 34, 35} plays a crucial role. The duality symmetry was determined to be the group $SL(2,\mathbb{Z})$ for simply laced gauge groups and $\Gamma_0(4)$ for the $B$ and $C$ type gauge groups \cite{36, 37, 38}. Moreover, the $S_2$ generator of the Hecke group exchanges the $B$ and $C$ type systems. An infrared counterpart to these duality groups are present in our integrable systems, which allow for a (generalized) duality group action on the infrared modular parameter $\tau$ \cite{24}, inherited after mass deformation from the $\mathcal{N} = 4$ duality. Note in particular that the requirement of the $B$ type and $C$ type exchange is implemented in our integrable system by the Langlands duality we discussed in subsection 2.2. This duality provides a further consistency check on the relative weight of the short and long root contributions, fixed in \cite{14} through consistency with the superpotential of the pure $\mathcal{N} = 1$ super Yang-Mills theory.

In \cite{14}, following the reasonings in \cite{11, 13, 6, 12}, an exact effective superpotential for $\mathcal{N} = 1^*$ was proposed for any gauge group, equal to the potential of the twisted elliptic Calogero-Moser model. The arguments were based on holomorphy, uniqueness of the deformation from $\mathcal{N} = 2^*$, the form of non-perturbative contributions, and integrability. We have added to these reasonings the test of $S$-duality in subsection 2.2. We wish to further strengthen the arguments for the superpotential by comparing the results for the exact quantum vacua with semi-classical results. We will find both confirmations and surprises.

3.1 Semi-classical Vacua

A semi-classical analysis of the massive vacua of $\mathcal{N} = 1^*$ proceeds in several steps. First one solves the equations of motion for constant scalar field configurations which are equivalent to the statement that the three complex scalars satisfy a $su(2)$ algebra. The enumeration of inequivalent embeddings of $su(2)$ in the gauge algebra then provides the set of classical solutions. In a second step, one analyzes the unbroken gauge group for each classical vacuum, and then counts the number of vacua that the corresponding pure $\mathcal{N} = 1$ quantum theory gives rise to in the infrared (using e.g. the index calculation \cite{39}). For gauge algebra $su(n)$ the number of classical vacua was thus argued to be equal to the sum of the divisors of $n$ \cite{5}, and this number coincides with the number obtained from the exact superpotential \cite{5, 12}. For other gauge algebras, the semi-classical counting of vacua was performed in \cite{10}. For gauge algebra $so(n)$ it was argued to be:

$$Z_{\text{semi-class}}(x, y) = 1 + x + x^2 y + 3 x^3 + 6 x^4 + x^5 (6 + y) + x^6 (7 + 3 y) + x^7 (15 + 2 y) + x^8 (26 + y^2) + x^9 (31 + 5 y) + \ldots$$  \(3.1\)

\(^{13}\) Note that the dual to gauge group $G/C$ has gauge group $\hat{G}$. The two scalars above are interchanged under $S$-duality. Thus, the duality symmetries mix various global choices of gauge groups.

\(^{14}\) Again, the behaviour of the center of the covering group of the gauge group under $S$-duality is known – our discussion is here at the level of the algebra.
where the power of $x$ is equal to $n$ and the power of $y$ is the number of massless $U(1)$’s in a given massless branch of vacua. Although we will concentrate on massive vacua, let us remark that the semi-classical counting of massless vacua may well be futile in the full quantum theory, where there may be a single manifold of massless vacua of given rank [47] (albeit with different branches). Thus, we will only further consider the semi-classical formula (3.1) for $y = 0$. For low rank then, the formula gives the following number of massive vacua, semi-classically:

$$\text{so}(5) : \text{sc} 6 \quad \text{so}(6) : \text{sc} 7 \quad \text{so}(7) : \text{sc} 15 \quad \text{so}(8) : \text{sc} 26.$$  \hspace{1cm} (3.2)

We know the result for $\text{so}(6) = \text{su}(4)$ to be exact. We moreover have that this counting of $\text{so}(2r + 1)$ vacua agrees with the semi-classical counting of vacua of $\text{sp}(2r)$ [12]. In the following, we compare the predictions for some low rank gauge groups to the results we obtained for the massive vacua coded in the superpotential. To make the comparison, we need to go into a little more detail of the semi-classical analysis.

### 3.2 Low Rank Case Studies of Quantum Vacua

In this subsection, we compare the analysis of integrable system extrema to the semi-classical analysis of massive vacua of $N = 1^*$ gauge theory case by case. This will also be the occasion to interpret the many duality properties that we found for the integrable systems in section 2. We briefly comment on the monodromies.

To wrap up a loose end first, let us note that the minimal mass $M_i$ of a given vacuum $i$ can be computed using the equation

$$M_i^2 = \min \left[ \text{Spec} \left( \mathcal{M}_i^T \mathcal{M}_i \right) \right],$$  \hspace{1cm} (3.3)

where $\mathcal{M}_i$ is the matrix of second derivatives of the potential in vacuum $k$:

$$(\mathcal{M}_k)_{ij} = \frac{\partial^2 V_k(X)}{\partial X_i \partial X_j}.$$  

This clarifies the logic behind our definition of isolated extrema of the integrable system (see equation (2.12) and the corresponding footnote).

The case $\text{so}(5)$

We expect six vacua semi-classically. Let’s recall in a little more detail how this counting arises. We allow for various five-dimensional representations of $\text{su}(2)$ as vacuum expectation values for the three scalars $\phi_i$ of $N = 1^*$. Even-dimensional representations must appear in even numbers. They need to take values in the gauge Lie algebra, and we classify them up to gauge equivalence. One then finds the following allowed representations [40] – we indicate the dimensions of the $\text{su}(2)$ representations, the unbroken part of the gauge group, and then the number of massive vacua they give rise to in the infrared:

$$\begin{align*}
5 &: 1 : 1 \\
3 + 1 + 1 &: \text{so}(2) : 0 \\
2 + 2 + 1 &: \text{sp}(2) : 2 \\
1 + 1 + 1 + 1 + 1 &: \text{so}(5) : 3 .
\end{align*}$$  \hspace{1cm} (3.4)

For instance, the $2 + 2 + 1$ dimensional representation breaks the gauge algebra down to $\text{sp}(2)$. Classically, this gives rise to a pure $N = 1$ theory with $\text{sp}(2)$ gauge algebra at low energies, which gives rise to two quantum vacua. Summing all the resulting numbers of semi-classical vacua, we find six massive vacua in total.

When we compare this analysis to the exact quantum vacua that we found for $\text{so}(5)$, we remark that we have a neat correspondence. In particular, there is one vacuum, on the real axis, that we can identify in the exact quantum regime as the fully Higgsed vacuum (corresponding to the 5-dimensional representation of $\text{su}(2)$ in the list (3.4)). Its S-dual we interpret as a confining vacuum, and it is a triplet under the T-transformation, agreeing neatly with the $\text{so}(5)$ confining vacua (corresponding to the trivial representation of $\text{su}(2)$ in (3.4)). We moreover found a doublet under T-transformation, again in agreement with the two vacua corresponding to the $\text{sp}(2)$ classical vacuum. Thus, at this level, we find excellent agreement.

We note that the analysis of section 2 demonstrates that the six vacua are in a single $SL(2,\mathbb{Z})$ sextuplet and that their transformation properties are in correspondence with the transformation properties of sublattices of the torus lattice. Their (generalized) S-duality and T-duality properties are entirely known.

The exact analysis has revealed a seventh vacuum. It does not have a semi-classical counterpart in the analysis of [40]. It is a singlet under S-duality and T-duality transformations. We observe that the
seventh extremum (due to its positioning at $\tau/2$ for all extremal points) is associated to a Wilson line which corresponds to the fundamental spinorial weight of $so(5)$. This is the element of the weight lattice divided by the root lattice that generates the center $\mathbb{Z}_2$. One can analyze the semi-classical configurations that contribute near this extremum, by taking the limit discussed in subsection 2.9. Still, we note that the variables we use to describe the gauge theory in the ultraviolet are entirely different from the variables we use to describe the gauge theory physics in the infrared. Thus it remains hard to pinpoint the precise disconnect between the semi-classical and the exact quantum analysis.

We have computed the masses of the vacua. They are all roughly of the same order, and much above the accuracy of our numerical approximations, thus guaranteeing that our vacua are indeed massive. Moreover, for a given massive vacuum, the values of the masses are all approximately within a factor of 100 from each other. Interesting patterns in the (ratios) of masses (of various vacua) exist – it should be fruitful to study them systematically.

**The case $so(8)$**

In the case of the gauge algebra $so(8)$, we find a further set of surprises. First, let’s compare the quantum vacua to the semi-classical analysis. The semi-classical analysis yields [10]:

\[
\begin{align*}
7 + 1 & : H : 1_s \\
5 + 3 & : H : 1_s \\
5 + 1 + 1 + 1 & : so(3) : 2 \\
4 + 4 & : sp(2) : 2^* \\
3 + 3 + 1 + 1 & : so(2) \times so(2) : 0 \\
3 + 2 + 2 + 1 & : sp(2) : 2_s \\
3 + 1 + 1 + 1 + 1 + 1 & : so(5) : 3 \\
2 + 2 + 2 & : sp(4) : 3^* \\
2 + 2 + 1 + 1 + 1 + 1 & : sp(2) \times so(4) : 6_s \\
1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 & : so(8) : 6_s
\end{align*}
\]

for a total of 26 massive vacua. The semi-classical analysis was done under the assumption that the $\mathbb{Z}_2$ outer automorphism of $so(2N)$ is a gauge symmetry [10], in contrast to our analysis in section 2. If we adopt this point of view, we are left with a single $\mathbb{Z}_2$ global symmetry, and we have indicated in the counting above whether a set of vacua are a singlet ($s$) or are conjugate ($^*$) under that remaining $\mathbb{Z}_2$.

Using this analysis, and the T-duality transformation properties of the integrable system extrema, we can partially match the list of semi-classical and quantum vacua. The 6 under the T-duality group makes for a match between extrema 10, 11, 12, 13, 14, 15 and the $su(2)$ representation $1+1+1+1+1+1+1$. These correspond to the confining vacua. The doublets which are conjugate under the remaining global $\mathbb{Z}_2$ match extrema 3 and 4 (as well as their $\mathbb{Z}_2$ reflections) to the representations $4+4$ and $5+1+1+1$. The conjugate triplets match 6, 7, 8 (as well as their $\mathbb{Z}_2$ reflections) onto $3+1+1+1+1+1$ and $2+2+2+2$. The smaller representations of the T-duality group are harder to match. We can still identify the Higgs vacuum with the extremum number 9, which lies on the real axis and which we can therefore follow all the way to weak coupling. For other extrema, again, it is hard to follow the change of effective description of the gauge theory dynamics from the ultraviolet to the infrared. There is again a mismatch of one in the total number. Taking into account the partially gauged global symmetry, we find 27 vacua in the quantum theory, while semi-classically we only have 26.

The modular analysis of extrema also obtains a gauge theory interpretation. Recall that we found a singlet, triplet and quadruplet under the modular group. The modular group plays the role of a generalized duality group [24], acting on the effective gauge coupling in the infrared.

Note that we also found a more surprising feature: a new duality group, with a generator corresponding to a monodromy around a point in the fundamental domain of the effective coupling that we used to describe our theory. We found a duodecuplet of vacua transforming under this new duality group. It could be very interesting to understand this group better in terms of gauge theory physics, or, as associated to the choice of parameterisation in the infrared.

Again, the masses all lie very amply above our numerical accuracy, such that we can claim that we indeed identified massive vacua. Masses are again within a factor of 100 or so from each other, and exhibit interesting patterns that could be explored.
For gauge algebra $so(7)$, the semi-classical analysis predicts fifteen massive vacua, that arise as follows:\footnote{\[40, 42\]}:

\begin{align*}
7 : & \ 1 : 1 \\
5 + 1 + 1 : & \ so(2) : 0 \\
3 + 3 + 1 : & \ so(2) : 0 \\
3 + 2 + 2 : & \ sp(2) : 2 \\
3 + 1 + 1 + 1 : & \ so(4) : 3 \\
2 + 2 + 1 + 1 + 1 : & \ sp(2) \times so(3) : 4 \\
1 + 1 + 1 + 1 + 1 + 1 : & \ so(7) : 5. \quad (3.6)
\end{align*}

In the quantum theory, we do find a quintuplet under T-duality associated to the confining vacuum on the imaginary axis, dual to the Higgs vacuum on the real axis, near weak effective coupling. It enhances to a septuplet under T-duality at stronger effective coupling. It seems from our analysis that the quantum theory on $\mathbb{R}^3 \times S^1$ permits two more quantum vacua, and that the multiplet structure under T-duality is blurred at strong effective coupling.

### 3.3 Tensionless Domain Walls, Colliding Quantum Vacua and Masslessness

The point in the fundamental domain around which we have found a monodromy in the case of the $so(8)$ gauge algebra, corresponds to a point at which two massive vacua have equal superpotential. At this point, a supersymmetric domain wall between the vacua becomes tensionless\footnote{\[43, 44\]}. The physics associated to such a situation is hard to discuss in detail, because of the difficulty of controlling the Kähler potential in gauge theories with $N = 1$ supersymmetry only. Explorations of the physics in this regime can be found in\footnote{\[45, 41, 46\]}. We note in particular that in a mass and cubically deformed $N = 1$ $U(N)$ theory in\footnote{\[45, 46\]}, an extension of the $\mathbb{Z}_N$ action associated to shifts in the $\theta$ angle of the gauge theory to $\mathbb{Z}_{N-2}$ was observed due to the presence of a point of monodromy in an effective coupling. The T-operation (shifting the $\theta$ angle of the gauge theory) in our situation is also crucially influenced by the presence of the point of monodromy \footnote{\[43\]}: above the point of monodromy (at weak effective coupling), we find a $\mathbb{Z}_N$ action, while below (at strong effective coupling), we find a $\mathbb{Z}_N$ action (for the case $N = 8$ as well as for the case of $N = 7$). We also note that the collision of the extrema of the superpotential indicates the existence of an effectively massless excitation since there will be a zero mode for the matrix of second derivatives. The physics, or at least the properties of the effective description, seem close to the discussion in e.g.\footnote{\[45\]}. It would be interesting to elucidate this point further.

### 4 Conclusions and Open Problems

We studied the isolated extrema of complexified elliptic Calogero-Moser models, and encountered a plethora of beautiful phenomena. The values of the integrable interparticle potential at the extrema are true vector-valued modular forms in some cases, allowing for an analytic determination of the extrema in terms of modular forms of congruence subgroups of the modular group. This gives rise to webs of extrema that form representations under the duality group of the model. The latter can either be a modular or a Hecke group. A more intricate phenomenon is the appearance of monodromies amongst a second class of extrema as we loop around a point in the fundamental domain of the modular group. The duality group is then enlarged to include the monodromy generator. We determined the action of these generators on extrema. Moreover, we provided a wealth of Fourier coefficients of the extremal potential. These analyses can be viewed as a considerable widening of the observation of the integrality of observables in equilibria of integrable systems.

Secondly, we interpreted the results on extrema of Calogero-Moser systems in terms of mass-deformed $\mathcal{N} = 4$ supersymmetric gauge theory in four dimensions. We compared our results based on a low-energy effective action for the quantum theory to semi-classical predictions. The total number of quantum vacua only approximately matched the number resulting from a semi-classical analysis. The precise multiplet structures in the quantum theory showed surprising features, including monodromy properties of the quantum vacua.

It should be clear that we only scratched the surface of this intriguing domain at the intersection of integrable systems, modularity and gauge theory. The new features of the extrema that we laid bare in the $B, C, D$-type integrable models (compared to the $A$-type theories) prompts the question of the generic counting of the extrema, the relevant duality group and modular structure (including monodromies) as well as their representation and number theoretic content. Clearly, our analysis begs to be extended to
exceptional algebras of low rank, to higher rank root systems, to models with different choices of coupling constants, as well as to the integrable generalizations of the elliptic Calogero-Moser models, including for instance the Ruijsenaars model with spin. Moreover, our study can be extended to other observables, like the ratio of the frequencies of fluctuations. It would also be interesting to attempt to characterize the positions of the extrema through e.g. a generalization of zeroes of orthogonal polynomials [23]. All indications are that similarly intriguing phenomena as the ones we uncovered will appear in this broader field.

In gauge theory, one would like to analyze more closely the Seiberg-Witten curves of the $\mathcal{N} = 2^*$ theories that underlie our models, and in particular, locate the points in Coulomb moduli space where the curve develops a number of nodes equal to the rank of the gauge group, and where the vanishing cycles are mutually local (indicating the existence of massive vacua after mass deformation). The Seiberg-Witten curves are defined by equations of higher order, rendering this analysis harder than in the cases treated in detail so far [3].

One would also like to have access to the large rank generalization of our results, to connect to holographic dual backgrounds with orientifold planes [43, 24, 40]. For these purposes it might suffice to have access to the large rank generalization of a Higgs and confining vacuum, which one may hope to characterize analytically. It would also be useful to perform a careful analysis of the discrete choices of gauge groups and line operators in our model, to classify various supersymmetric vacua further [31, 32], e.g. by understanding a single phase, then chasing it through the duality chains.

Finally, we already noted in passing that the branches of massless vacua predicted by the semi-classical analysis may turn out to be connected in the quantum theory, giving rise to a single massless vacuum manifold, consisting of branches that can be characterized by differing algebraic equations [47]. Our numerical explorations up to now are consistent with the fact that all massless vacua have the same value of the superpotential. It would be interesting to clarify the structure of these vacuum manifolds further for the models at hand.

## A Lie Algebra

Useful data on the Weyl group, the outer automorphisms and the dual Coxeter number of classical Lie algebras are summarized in table 2:

| Algebra | Weyl group | Outer Automorphisms | Dual Coxeter number |
|---------|------------|---------------------|---------------------|
| $A_r$, $r > 1$ | $S_{r+1}$ | $Z_2$ | $r + 1$ |
| $A_1$ | $Z_2$ | 1 | 2 |
| $B_r$ | $S_r \ltimes Z_r^r$ | 1 | $2r - 1$ |
| $C_r$ | $S_r \ltimes Z_r^2$ | 1 | $r + 1$ |
| $D_{r}$, odd $r$ | $S_r \ltimes Z_r^{r-1}$ | $Z_2$ | $2r - 2$ |
| $D_{r}$, even $r > 4$ | $S_r \ltimes Z_r^{r-1}$ | $Z_2$ | $2r - 2$ |
| $D_4$ | $S_4 \ltimes Z_3$ | $S_3$ | 6 |

Table 2: Lie Algebra Data

We also briefly discuss the periodicities of the twisted elliptic integrable systems in terms of Lie algebra concepts. The lattice of weights $\lambda$ corresponding to the Lie algebra root system $\Delta$ is defined by the relation

$$\forall \alpha \in \Delta, \langle \alpha^\vee, \lambda \rangle \in \mathbb{Z},$$

where the co-roots $\alpha^\vee$ are defined in terms of the roots $\alpha$ by the duality map:

$$\alpha^\vee = \frac{2\alpha}{\langle \alpha, \alpha \rangle}.$$ (A.2)

Thus for a long root (normalized to have length squared two) $\langle \alpha_l, \lambda \rangle \in \mathbb{Z}$ while for a short root of the $B$ or $C$ algebras we have $\langle \alpha_s, \lambda \rangle \in \frac{1}{2}\mathbb{Z}$, for all weights $\lambda$. As a consequence, due to the appearance of the (twisted) Weierstrass function in the potential, the periodicity is the weight lattice in the $\omega_1$ direction. If we define the co-weights $\lambda^\vee$ by the demand $\langle \alpha, \lambda^\vee \rangle \in \mathbb{Z}$, then, by the definition of the elliptic integrable system potential, the co-weight lattice equals the lattice of periods in the $\omega_2$ direction. We use these facts in section 2.
B  Elliptic Functions

Our conventions for the elliptic Weierstrass function are:

\[
\wp(x; \omega_1, \omega_2) = \frac{1}{x^2} + \sum_{(m,n) \not= (0,0)} \left( \frac{1}{(x + m\omega_1 + n\omega_2)^2} - \frac{1}{(2m\omega_1 + 2n\omega_2)^2} \right)
\]

\[
\wp(z; \tau) = \frac{1}{z^2} + \sum_{(m,n) \not= (0,0)} \left( \frac{1}{(z + m\tau + n)^2} - \frac{1}{(m + n\tau)^2} \right)
\]

which entails the equality

\[
\wp(z; \tau = \omega_2/\omega_1) = 4\omega_1^2 \wp(2\omega_1 z; \omega_1, \omega_2).
\]

We impose the convention that \( \Im(\omega_2/\omega_1) = \Im(\tau) > 0 \). The Weierstrass function is a Jacobi form of level 2 and index 0:

\[
\wp \left( \frac{z}{c\tau + d}; \frac{a\tau + b}{c\tau + d} \right) = (c\tau + d)^2 \wp(z; \tau).
\]

It has the following expansion for large imaginary part of \( \tau \):

\[
\wp(x; \omega_1, \omega_2) = -\frac{\pi^2}{12\omega_1^2} E_2(q) + \frac{\pi^2}{4\omega_1^2} \csc^2 \left( \frac{\pi x}{2\omega_1} \right) - \frac{\pi^2}{\omega_1^2} \sum_{n=1}^{\infty} nq^n \cos \frac{n\pi x}{\omega_1}.
\]

For the twisted Weierstrass functions, we can derive the equalities:

\[
\wp(x; \omega_1, \omega_2) + \wp(x + \omega_1; \omega_1, \omega_2) = \wp(x; \omega_1/2, \omega_2) + \frac{\pi^2}{6\omega_1^2} (2E_2(\omega_2/\omega_1) - E_2(\omega_2/\omega_1))
\]

\[
\wp(x; \omega_1, \omega_2) + \wp(x + \omega_2; \omega_1, \omega_2) = \wp(x; \omega_1, \omega_2/2) - \frac{\pi^2}{6\omega_1^2} (E_2(\omega_2/\omega_1) - \frac{1}{2} E_2(\omega_2/2\omega_1)).
\]

These can be proven using the definition of the Weierstrass function \( \wp \), as well as the definition of the second Eisenstein series \( E_2 \).

C  Modular Forms

We present a compendium of modular forms that we put to use in the bulk of our paper.

C.1 Theta and Eta Functions

We first fix our conventions for the theta-functions with characteristics:

\[
\theta \left[ \begin{array}{c} \alpha \\ \beta \end{array} \right] (\tau) = \sum_{n \in \mathbb{Z}} \exp \left[ \pi(n + \alpha)^2 \tau + 2\pi i \beta(n + \alpha) \right].
\]

Particular examples of these theta-functions include:

\[
\theta_2(q) = \theta \left[ \begin{array}{c} 1 \\ 0 \end{array} \right] (q) = 2q^{1/8} + 2q^{9/8} + 2q^{25/8} + 2q^{39/8} + ...
\]

\[
\theta_3(q) = \theta \left[ \begin{array}{c} 0 \\ 0 \end{array} \right] (q) = 1 + 2q^{1/2} + 2q^2 + 2q^{9/2} + 2q^8 + ...
\]

\[
\theta_4(q) = \theta \left[ \begin{array}{c} 0 \\ 1 \end{array} \right] (q) = 1 - 2q^{1/2} + 2q^2 - 2q^{9/2} + 2q^8 + ...
\]

We also make use of the Dedekind eta-function:

\[
\eta(q) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n),
\]

and the Klein invariant

\[
j(q) = 1728 \frac{E_4^3(q)}{E_4(q) - E_6(q)} = \frac{1}{q} + 744 + 196884q + ...
\]

(C.1)
C.2 Modular Forms and Sublattices

In this subsection we recall how to find a basis of the space of modular forms of weight \( k \) for the congruence subgroup \((\Gamma(N))\):

\[
\Gamma(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mod N \right\}.
\]

First we note that the cusps of \( \Gamma(N) \) can be identified with the pairs \( \pm v \in (\mathbb{Z}/N\mathbb{Z})^2 \) of order \( N \). This makes it possible to count the number of such cusps:

\[
\epsilon_\infty(\Gamma(N)) = \begin{cases} 
3 \frac{N^2}{2} \prod_{p|N} \left(1 - \frac{1}{p}\right) & N = 2 \\
N^2 \prod_{p|N} \left(1 - \frac{1}{p}\right) & N \geq 3.
\end{cases}
\]

For any congruence subgroup \( \Gamma \) the space of modular forms \( \mathcal{M}_k(\Gamma) \) of weight \( k \) decomposes into the subspace of cusp forms and the Eisenstein space: \( \mathcal{M}_k(\Gamma) = \mathcal{S}_k(\Gamma) \oplus \mathcal{E}_k(\Gamma) \). For \( N = 2 \) we have

\[
dim \mathcal{S}_2(\Gamma(2)) = 0
\]

and for \( N \geq 3,
\]

\[
dim \mathcal{S}_2(\Gamma(N)) = 1 + \frac{N^2(N-6)}{24} \prod_{p|N} \left(1 - \frac{1}{p^2}\right).
\]

In particular, \( \dim \mathcal{S}_2(\Gamma(3)) = 0 \) and \( \dim \mathcal{S}_2(\Gamma(6)) = 1 \).

We want an explicit basis of the Eisenstein space. For any vector \( v = \begin{pmatrix} c \\ d \end{pmatrix} \in (\mathbb{Z}/N\mathbb{Z})^2 \) of order \( N \), and for \( k \geq 3 \), we define the (non-normalized) Eisenstein series

\[
G_{k,N}[v](\tau) = G_{k,N} \begin{pmatrix} c \\ d \end{pmatrix}(\tau) = \sum_{v' \equiv v(N)} \left( \frac{c'}{N}\right)^k,
\]

and for weight two

\[
G_{2,N}[v](\tau) = G_{2,N} \begin{pmatrix} c \\ d \end{pmatrix}(\tau) = \frac{1}{N^2} \left[ \nu \left( \frac{c\tau + d}{N}, \tau \right) + G_2(\tau) \right],
\]

where the primed sum runs over those non-vanishing vectors \( v' = \begin{pmatrix} c' \\ d' \end{pmatrix} \) that equal \( v \) modulo \( N \). One can show that the Fourier expansion of these functions in terms of \( q = e^{2i\pi \tau} \) is:

\[
G_{k,N} \begin{pmatrix} c \\ d \end{pmatrix}(q) = \delta(c)\zeta_d^k(k) + \frac{(-2\pi i)^k}{N^2(k-1)!} \sum_{n=1}^{\infty} \sigma_{k-1,N} \frac{c}{d}(n) q^{n/N},
\]

where

\[
\sigma_{k-1,N} \frac{c}{d}(n) = \sum_{m|n \text{ and } \frac{c}{d}(m) \equiv c(N)} \text{sgn}(m)m^{k-1} \exp \left( 2\pi i \frac{dm}{N} \right)
\]

and

\[
\zeta^d_k(k) = \sum_{d' \equiv d(N)} \frac{1}{(d')^k}.
\]

This Fourier expansion is valid for all \( k \geq 2 \), including \( k = 2 \) which is the case we are mostly interested in.

For \( k \geq 3 \), any set \( \{G_{k,N}[v]\} \) with one \( v \) corresponding to each cusp of \( \Gamma(N) \) represents a basis of the space \( \mathcal{E}_k(\Gamma(N)) \) of Eisenstein series of weight \( k \) on \( \Gamma(N) \) (and in particular \( \dim \mathcal{E}_k(\Gamma(N)) = \epsilon_\infty \)). For the case \( k = 2 \) these statements have to be modified, because of the lack of modularity of the (ordinary) weight 2 Eisenstein series. It turns out that \( \dim \mathcal{E}_2(\Gamma(N)) = \epsilon_\infty - 1 \), and that \( \mathcal{E}_2(\Gamma(N)) \) is the set of linear combinations of the \( \{G_{k,N}[v]\} \) (where \( v \in (\mathbb{Z}/N\mathbb{Z})^2 \) is of order \( N \)) whose coefficients sum to 0\(^{15}\).

The Eisenstein series \( G_{k,N}[v] \) have good transformation properties under \( SL(2,\mathbb{Z}) \) for \( k \geq 3 \) and \( N \in \{2,3\} \) provided the vector \( v \) is transformed accordingly\(^{16}\):

\[
\frac{1}{(c\tau + d)^k} G_{k,N}[v] \left( \frac{a\tau + b}{c\tau + d} \right) = G_{k,N} \left[ \begin{pmatrix} a & b \\ c & d \end{pmatrix} v \right](\tau).
\]

\(^{15}\)Theorem 4.6.1 in \([30]\).

\(^{16}\)For generic \( N \) the relation between the normalized Eisenstein series, which enjoy these good transformation properties, and the series \( G_{k,N}[v] \) is not simply a proportionality relation (see formula (4.5) in \([30]\)), but it is a simple rescaling for \( N = 2 \) and \( N = 3 \).
For \( k = 2 \), we have to take into account a non-holomorphic term, except for linear combinations where the sum of the coefficients vanishes, as is the case for the potentials considered in the bulk of the paper.

Finally, we also define

\[
E_{2,N}(\tau) = E_2(\tau) - NE_2(N\tau) .
\]

These are weight 2 modular forms of \( \Gamma_0(N) \). We use extensively the fact that \( \mathcal{M}_2(\Gamma_0(4)) \) has dimension 2 and is generated by

\[
-E_{2,2}(q) = 1 + 24q + 24q^2 + 96q^3 + 24q^4 + 144q^5 + ... \\
-E_{2,4}(q) = 3 + 24q + 72q^2 + 96q^3 + 72q^4 + 144q^5 + ...
\]

We note the transformation property of the form \( E_{2,2} \) under \( \tau \to -1/(2\tau) \):

\[
E_{2,2}(-1/(2\tau)) = E_2(-1/(2\tau)) - 2E_2(-1/\tau) = -2\tau^2 E_{2,2}(\tau) .
\]

D The List of Extrema

In this appendix, we list the extrema of the complexified (twisted) elliptic Calogero-Moser models with root systems \( D_3 = \text{so}(8) \) and \( B_3 = \text{so}(7) \). We provide a few more details on how we obtained them, how to relate them through dualities, as well as Fourier expansions of the extremal potentials.

D.1 The List of Extrema for \( \text{so}(8) \)

The strategy we used to find extrema boils down to finding all the minima (which are also zeros) of the (auxiliary, gauge theory) potential \( \psi \) with non vanishing mass \( \sigma \) using a simple gradient algorithm with random initial conditions. Then we identify those configurations that are related by one of the symmetries we quotient by. This procedure is executed at a given value of \( \tau \). Once the complete list of extrema is known, we can follow a given extremum along any curve in the \( \tau \) upper half plane, by adiabatically varying \( \tau \). The T-dual extrema and the monodromies are obtained in this way, while the action of S-duality is known exactly. We thus unfold the whole web of dualities.

In order to determine the potential at the extremum, we first make use of our knowledge of T-duality, which dictates the Fourier expansion variable \( q^{1/n} \), where \( n \) is the smallest positive integer such that \( \tau^n \) acts trivially on the extremum under consideration. Then we evaluate the extremal potential at many different values of \( \tau \) and find recursively the rational Fourier coefficients.

D.1.1 The diagrams of the extremum

In the diagrams that follow, the black dots represent the values of the components \( X_i, \ i = 1, 2, 3, 4 \) at the extremum. The dark grey dots are images under the symmetries discussed in section 2.5.

In some of the diagrams, there are five black dots instead of four, reflecting the fact that they represent three extrema related by the global \( S_3 \) symmetry. For every such extremum, one subgroup \( \mathbb{Z}_2 \subset S_3 \) acts trivially. One of the three extrema is obtained by choosing one of the circled black dots and the three ordinary black dots, a second one is obtained by choosing the other circled black dot and the three black dots, while the third is determined by the four small black dots. (The pale grey dots show the possible translations of this extremum by half-periods.)

We note in passing that some exact information on the positioning of the extremum is available. For instance, for extremum number 9, some exact information on the positions is the following. At \( \tau \to i\infty \), the system reduces to the Sutherland system (with trigonometric potential). According to [10], the positions at equilibrium are related to the roots of a Jacobi polynomial. Explicitly in the case of \( D_4 \), the polynomial is \( P_2^{(1,1)}(y) = \frac{15}{16}(y - 1)^2 + \frac{15}{16}(y - 1) + 3 \), from which we deduce the positions \( X_1 = 0, X_{2,3} = \frac{1}{\sqrt{5}} \) and \( X_4 = \frac{1}{2} \). For \( \tau \to 0 \), the positions converge on \( X_1 = 0, X_2 = 1/6, X_3 = 1/3 \) and \( X_4 = \frac{1}{2} \). This numerical convergence is slow.

S-duality guarantees that the situation is similar for the extremum on the imaginary axis, with the two limits exchanged. Moreover, T-duality then acts in the \( \tau \to i\infty \) limit as \( X_0 \to X_0, X_1 \to X_1 + 1/6, X_2 \to X_2 + 1/3, X_3 \to X_3 + 1/2 \). (These transformations are exact within the precision of the numerics.) This generates the 6-cycle. Et cetera.
Extrema at $\tau = i$ for so(8)
D.1.2 The series for the $so(8)$ extremal potentials

We have been able to determine the $q$-expansions of the potentials in each extremum with great accuracy, in terms of functions with integer coefficients. For extrema 1 to 8, we gave the exact expression in section 2.7. To list the series for the remaining extrema, we introduce 11 functions, for which we only reproduce...
the first few coefficients – more can be obtained –:

\[
\begin{align*}
f_1(q) &= \frac{1}{1000} - 467q + 45379q^2 - 2393958092q^3 - 4404434737431q^4 - 71196036580667762q^5 + \ldots \\
f_2(q) &= 1 - 15172q + 51582918q^2 - 397077052296q^3 + 5101142359347277q^4 + 9430056917523369780q^5 + \ldots \\
f_3(q) &= \frac{1}{600} + q + 369q^2 + 68644q^3 + 11490041q^4 + 1579638246q^5 + \ldots \\
f_4(q) &= 1 + 3096q + 1818378264q^2 + 2446348866170976q^3 + 4535490910062930456600q^4 + \ldots \\
f_5(q) &= 1 - 142284q - 2825331513294q^2 - 1102417262675887640q^3 + \ldots \\
f_6(q) &= 2 + 780960q + 18367562372664q^2 + 76287553034263440144q^3 + \ldots \\
f_7(q) &= 1 - 4478868q - 121113750523626q^2 - 5314750232983801186536q^3 + \ldots \\
f_8(q) &= \frac{1}{12}(14 + 79929712q + 2425403175787968q^2 + 111756708524847535116096q^3 + \ldots ) \\
f_9(q) &= \frac{1}{12}(-37 - 489421748q - 16364614670173794q^2 - 78763906596039662206584q^3 + \ldots ) \\
f_{10}(q) &= 1 - 12264q - 7273512936q^2 - 9785395464683424q^3 - 1814196367625172182628q^4 + \ldots \\
f_{11}(q) &= 1 + 110596q + 110757888006q^2 + 180011235750912008q^3 + 36776290659456694954381q^4 + \ldots 
\end{align*}
\]

The potentials then read

\[
\begin{align*}
V_9 &= 14400\pi^2 f_3 \left( \frac{q}{\pi} \right) \\
V_{10+k} &= -4\pi^2 \sum_{j=0}^{4} (16q)^j/6 \exp \left( 2\pi i \frac{5j}{6k} \right) f_{4+j} \left( \frac{q}{\pi} \right) \\
V_{16} &= -3\pi^2 (f_{10}(q) - 72\sqrt{q}f_{11}(q)) \\
V_{17} &= -3\pi^2 (f_{10}(q) + 72\sqrt{q}f_{11}(q)) \\
V_{19} &= -24\pi^2 (75f_1(q/15^3) + i\sqrt{5q/3}f_2(q/15^3)) \\
V_{20} &= -24\pi^2 (75f_1(q/15^3) - i\sqrt{5q/3}f_2(q/15^3)).
\end{align*}
\]

where \( k = 0, \ldots, 5 \). The last series \( V_{18} \) can then be deduced from the fact that the sum of all potentials in the duodecuplet vanishes. Note that the coefficients grow rapidly, preventing the functions above to be modular forms. The monodromy is responsible for this phenomenon, as can be confirmed by the estimation of the convergence radius given by the successive ratios of the coefficients (see figure 5).

**D.2 The List of Extrema for \( so(7) \) and \( sp(6) \)**

Finally, in the case of the algebras \( B_3 = so(7) \) and \( C_3 = sp(6) \), we only present diagrams of the extremal positions for the \( so(7) \) root system, since the corresponding extrema for \( sp(6) \) can be found by Langlands duality. We use the same conventions as for the \( so(5) \) figures. Additional data, like the data we presented for \( so(8) \) in the previous section, can be found.
