I. INTRODUCTION

Similar to quantum entanglement, the uncertainty principle is also one of the characteristic traits of quantum mechanics and is a fundamental departure form the principles of classical physics. Any pair of incompatible observables admit a certain form of uncertainty relation (e.g., an uncertainty inequality) and this constraint set ultimate bounds on the measurement precision achievable for these quantities. Since Heisenberg introduced the first uncertainty relation about the product of the standard deviations of canonical operators in 1927, the scientific community has raised the long-standing controversy over how to interpret and formulate the Heisenberg’s original spirit. How-ever, the conventional variance-based uncertainty relations possess a clear physical conception and still find a variety of applications in quantum information science, such as entanglement detection, quantum spin squeezing, and even quantum metrology. In fact, it is precisely because of the uncertainty relations that quantum theory imposes definite limits on the precision of measurement and the celebrated quantum Cramér-Rao bound can also be deduced from the Schrödinger-Robertson uncertainty relation.

Intuitively, it is a well-accepted mathematical structure that the conventional uncertainty relations provide lower bounds to the product or sum of the variances of incompatible Hermitian operators. Among the candidates, the most famous and popular form is the Robertson uncertainty relation (RUR)

\[ \Delta A \Delta B \geq \frac{1}{2} |\langle [A, B] \rangle|, \]

where the standard deviation \( \Delta O \) and expectation value \( \langle O \rangle \) are taken over the state \( |\Psi\rangle \). It is notable that the RUR can be derived from a slightly strengthened inequality, the Schrödinger uncertainty relation (SUR)

\[ \Delta A^2 \Delta B^2 \geq \left( \frac{1}{2} |\langle [A, B] \rangle| \right)^2 + \frac{1}{2} |\langle \tilde{A} \tilde{B} \rangle|, \]

where we define the operator \( \tilde{O} = O - \langle O \rangle I \) and \( I \) is the identity operator.

However, both the RUR and SUR suffer from the problem that they may be trivial even when \( A \) and \( B \) are incompatible on the state \( |\Psi\rangle \), for instance, \( |\Psi\rangle \) is an eigenstate of either \( A \) or \( B \). In order to fix this flaw, recently Maccone and Pati presented two stronger uncertainty relations based on the sum of variances and these inequalities are guaranteed to be nontrivial whenever \( |\Psi\rangle \) is not a common eigenstate of \( A \) and \( B \). The novel lower bound can be represented in a combination of both inequalities

\[ \Delta A^2 + \Delta B^2 \geq \max \{ \mathcal{L}_1, \mathcal{L}_2 \}, \]

where we define

\[ \mathcal{L}_1 = \pm i |\langle [A, B] \rangle| + |\langle \Psi | A \pm i B | \Psi^\perp \rangle|^2, \]

\[ \mathcal{L}_2 = \frac{1}{2} |\langle \Psi^\perp | A + B | \Psi \rangle|^2, \]

Here \( |\Psi^\perp \rangle \) is an arbitrary state orthogonal to \( |\Psi\rangle \) and \( |\Psi^\perp \rangle \) is specified according to the Vaidman’s formula

\[ \mathcal{O}|\Psi\rangle = \langle \mathcal{O} |\Psi\rangle + \Delta \mathcal{O}|\Psi^\perp\rangle. \]
Moreover, utilizing the same techniques employed to derive (4), Maccone and Pati also obtained an amended RUR [22]

$$\Delta A \Delta B \geq \frac{1}{2} \langle [A, B] \rangle / \left(1 - \frac{1}{2} \left[ \frac{\langle A \mid A \rangle}{\Delta A} \pm i \frac{B}{\Delta B} \right] \right)^2.$$

(7)

In this work, we try to look at such a problem from another perspective. Given two noncommuting operators $A$ and $B$, we can define the uncertainty functional $U(\Psi) = \Delta A^2 \Delta B^2$. Indeed, the RUR and SUR follow directly from the uncertainty equality

$$U(\Psi) = \left[ \frac{1}{2} \langle [A, B] \rangle \right]^2 + \left[ \frac{1}{2} \langle [\hat{A}, \hat{B}] \rangle \right]^2 + R(\Psi),$$

(8)

where $R(\Psi)$ is a positive semidefinite remainder term, emerging from the application of the Cauchy-Schwarz inequality to $\langle \hat{A}^2 \rangle \langle \hat{B}^2 \rangle$. Can we construct other uncertainty equalities $\forall A, B$ and obtain another functional $W(\Psi) = \Delta A^2 + \Delta B^2$, which can straightforward lead to the inequalities derived in Ref. [22]? Here we show that the answer is affirmative and elucidate the physical meaning behind these inequalities.

An outline of the reminder of the paper is as follows. In Sec. II, we construct and formulate two quantum uncertainty equalities, which hold for all pairs of incompatible observables and imply the new uncertainty relations introduced by Maccone and Pati. Furthermore, we present an explicit interpretation lying behind the derivations and relate these relations to the so-called intelligent states. In Sec. III, we investigate the properties of these uncertainty inequalities in the qubit system and a state-independent bound is obtained for the sum of variances. In Sec. IV, we apply these inequalities to the spin squeezing scenario and its implication in interferometric sensitivity is also discussed. Finally, Sec. V is devoted to the discussion and conclusion.

II. UNCERTAINTY EQUALITIES IMPLY UNCERTAINTY RELATIONS

A. New uncertainty equalities

As indicated in Ref. [22], the lower bound $L_2$ is derived from the uncertainty equality

$$\Delta A^2 + \Delta B^2 = \frac{1}{2} \left[ \Delta (A + B)^2 + \Delta (A - B)^2 \right].$$

(9)

In fact, we can obtain another lower bound

$$L_3 = \frac{1}{2} \Delta (A - B)^2 = \frac{1}{2} \langle \Psi \rangle_{A - B} \Delta (A - B)^2.$$ 

(10)

In the following, we first construct and prove two uncertainty equalities which imply the uncertainty inequalities (4) and (5). Note that here we refer the lower bounds as to the corresponding uncertainty relations.

Uncertainty equality 1.

$$W(\Psi) = \pm i \langle [A, B] \rangle + \sum_{k=1}^{d-1} \left[ \langle \Psi \mid A \pm i B \rangle \Psi_k^\dagger \right]^2,$$

(11)

where $W(\Psi) = \Delta A^2 + \Delta B^2$ and $\{ \Psi_k^\dagger \}_{k=1}^{d-1}$ comprise an orthonormal complete basis in the $d$-dimensional Hilbert space.

Proof. For simplicity, let us define the operator $\Pi = I - \mid \Psi \rangle \langle \Psi \mid$ and the state $\mid \xi^\pm \rangle = (A \pm i B) \mid \Psi \rangle$. Note that $\Pi^2 = \Pi$, which is a projector of the Lüders type [5]. The $\pm$ sign in $\mid \xi^\pm \rangle$ is due to the symmetry between $A$ and $B$ since $W(\Psi)$ must be invariant under $A \leftrightarrow B$ (see below). We have

$$\langle \xi^\mp \mid \Pi \mid \xi^\pm \rangle = \langle \Psi \mid (A \pm i B) (I - \mid \Psi \rangle \langle \Psi \mid) (A \mp i B) \rangle \langle \Psi \mid \xi^\pm \rangle$$

$$= \langle \chi^\mp \mid \chi^\pm \rangle - \langle \chi^\mp \mid \Psi \rangle \langle \Psi \mid \chi^\pm \rangle$$

$$= \langle A^2 + B^2 \pm i [A, B] \rangle \langle A \mp i B \rangle$$

$$= \Delta A^2 + \Delta B^2 \mp i \langle [A, B] \rangle.$$ 

(12)

Since $\Pi$ is the orthogonal complement to $\mid \Psi \rangle$ (e.g., $(\langle \xi^\mp \mid \Psi \rangle = 0)$, we can choose an arbitrary orthogonal decomposition of the projector $\Pi$

$$\Pi = \sum_{k=1}^{d-1} \mid \Psi_k^\dagger \rangle \langle \Psi_k \mid,$$

(13)

where $\{ \mid \Psi_k^\dagger \rangle \}_{k=1}^{d-1}$ comprise an orthonormal complete basis in the $d$-dimensional Hilbert space. Combining Eqs. (12) and (13), we obtain the uncertainty relation (11).

Uncertainty equality 2.

$$U(\Psi)^{1/2} = \frac{\pm \frac{1}{2} \langle [A, B] \rangle}{1 - \frac{1}{2} \sum_{k=1}^{d-1} \left[ \langle \Psi \rangle_{A \pm i B} \Delta A \pm i \frac{B}{\Delta B} \right]}.$$ 

(14)

where $U(\Psi) = \Delta A^2 + \Delta B^2$ and $\{ \mid \Psi_k^\dagger \rangle \}_{k=1}^{d-1}$ comprise an orthonormal complete basis in the $d$-dimensional Hilbert space.

Proof. Similar to the above arguments, first define the unnormalized state vector $\mid \xi^\pm \rangle = (\Delta A \pm i \frac{B}{\Delta B}) \mid \Psi \rangle$. We have the identity

$$\langle \xi^\mp \mid \Pi \mid \xi^\pm \rangle = \langle \xi^\mp \mid \chi^\pm \rangle - \langle \xi^\mp \mid \Psi \rangle \langle \Psi \mid \chi^\pm \rangle$$

$$= \frac{A^2}{\Delta A^2} + \frac{B^2}{\Delta B^2} \mp i [A, B]$$

$$= \frac{\langle A \rangle \pm i [A, B]}{\Delta A} \frac{\langle B \rangle \pm i [B, A]}{\Delta B}$$

$$= 2 \mp i \langle [A, B] \rangle.$$

(15)

From Eqs. (13) and (14), we obtain the uncertainty relation (14). Note that we always assume that $\Delta A \Delta B \neq 0$, e.g., $\mid \Psi \rangle$ is not an eigenstate of either $A$ or $B$.
Before proceeding, some remarks can be made on the significance of the above two uncertainty equalities. First, if we retain only one term associated with $|\Psi^{-}\rangle \in \{ |\Psi_{k}^{-}\rangle \}^{d-1}_{k=1}$ in the summation and discard the others, the uncertainty equalities (11) and (14) reduce to the uncertainty inequalities (1) and (4), respectively. It is worth emphasizing that in contrast to the derivations in Ref. [22], the Cauchy-Schwarz inequality is not involved here. Moreover, the tightness of the inequality is indicated by the uncertainty equality. For example, when $|\Psi^{\perp}\rangle$ is of the form $|N\rangle$ (the normalization factor)

$$|\Psi^{\perp}\rangle = (A \mp i B - \langle A \mp i B \rangle) |\Psi\rangle / |N\rangle = \Pi|\chi^{\perp}\rangle / |N\rangle,$$  

(16)

it is easy to see that the contribution from all other terms in the summation of (11) vanishes

$$\sum_{k=2}^{d-1} |\langle A \mp i B | \Psi_{k}^{\perp}\rangle|^{2} = |N| \sum_{k=2}^{d-1} |\langle \Psi_{k}^{\perp} | \Psi_{k}^{\perp}\rangle|^{2} = 0,$$  

(17)

where we assume $|\Psi^{\perp}\rangle = |\Psi_{1}^{\perp}\rangle$. This result coincides with that of [22]. Therefore, in view of Ref. [22], we can naturally interpret the tightness of (11) or (14) as imposing constraints on the properties of $|\Psi^{\perp}\rangle$.

B. Interpretations of uncertainty inequalities

However, we still wonder why these seemingly curious expressions, such as $A \pm i B$ and $\frac{A}{\Delta A} \pm \frac{i B}{\Delta B}$, appear in these inequalities. Here we provide an explicit interpretation of (11) and (14), and the critical role of the intelligent states is highlighted. From this perspective, two significant types of states should be introduced: the ordinary intelligent states (OISs) provide an equality in the RUR [30, 31, 36, 37, 41], while the generalized intelligent states (GISs) do the same in the SUR [33]. It is clear that the OISs form a subset of the GISs and the set of OISs is unitarily equivalent to the set of GISs [33]. Most importantly, owing to the application of the Cauchy-Schwarz inequality, the GISs for operators $A$ and $B$ must satisfy the following characteristic eigenvalue equation [38, 41]

$$\frac{A + i \gamma B}{\Delta A} |\Psi\rangle = \lambda |\Psi\rangle,$$  

(18)

where $\gamma$ is an arbitrary complex number (e.g., $\gamma \in \mathbb{C}$) and the eigenvalue $\lambda = \langle A \rangle + i \gamma \langle B \rangle$. For the particular case of real $\gamma \in \mathbb{R}$, the eigenvalue equation (18) determines the OISs for operators $A$ and $B$ [41]. In addition, it should be emphasized that the concept of OISs is not equivalent to minimum-uncertainty states (MUSs) in general [21, 33, 37, 41], and we also obtain a constraint for $|\Psi\rangle$ which should be satisfied if $\mathcal{N}(\Psi)$ is to be a minimum

$$(A^{2} + B^{2}) |\Psi\rangle = (\Delta A^{2} + \Delta B^{2}) |\Psi\rangle.$$  

(19)

For more details, see Appendix A.

For further discussion, the necessary condition (18) can be rewritten as

$$\langle A + i \gamma B \rangle |\Psi\rangle = 0.$$  

(20)

By multiplying $\frac{\lambda A + i \gamma B}{\Delta A} |\Psi\rangle$ or $\frac{\lambda A - i \gamma B}{\Delta A} |\Psi\rangle$ upon (20), we have the following two equations [38, 40]

$$\Delta A^{2} - \gamma^{2} \Delta B^{2} = -i \gamma \langle F \rangle,$$  

(21)

$$\Delta A^{2} + \gamma^{2} \Delta B^{2} = \langle C \rangle,$$  

(22)

where we define the Hermitian operators

$$C = -i [A, B] = -i [\tilde{A}, \tilde{B}], \quad F = \{ \tilde{A}, \tilde{B} \}.$$  

(23)

Therefore, the solution to (21) and (22) is

$$\gamma = \frac{\langle C \rangle + i \langle F \rangle}{2 \Delta B^{2}}, \quad |\gamma|^{2} = \frac{\Delta A^{2}}{\Delta B^{2}}.$$  

(24)

where we still ignore the trivial cases and assume $\Delta A \Delta B \neq 0$.

Since the uncertainty relations (11) and (14) are both extensions to the RUR, we should concentrate on the special case of $\gamma \in \mathbb{R}$, that is, $\gamma = \pm \Delta A / \Delta B$. Therefore, the eigenvalue equation (18) can be recast as

$$\left( \frac{A}{\Delta A} \pm \frac{i B}{\Delta B} \right) |\Psi\rangle = \lambda |\Psi\rangle.$$  

(25)

Thus, if we define the following two quantities

$$\Theta_{1} = \left| \langle \Psi | \frac{A}{\Delta A} \pm \frac{i B}{\Delta B} |\Psi^{\perp}\rangle \right|^{2},$$  

(26)

$$\Theta_{2} = \left| \langle \Psi | A \pm i B |\Psi^{\perp}\rangle \right|^{2},$$  

(27)

it soon becomes clear that the value of $\Theta_{1}$ reveals the extent to which $|\Psi\rangle$ deviates from being an OIS, or more precisely, $\Theta_{1}$ characterizes the extent to which $\Delta A \Delta B$ deviates from $\langle [A, B] \rangle / 2$. Meanwhile, by noticing the inequality

$$\Delta A^{2} + \Delta B^{2} \geq 2 \Delta A \Delta B \geq |\langle [A, B] \rangle|,$$  

(28)

we realize that if we require $\Delta A^{2} + \Delta B^{2} = |\langle [A, B] \rangle|$, the condition $\Delta A = \Delta B$ must be satisfied. In this circumstance, the eigenvalue equation (25) reduces to

$$(A \pm i B) |\Psi\rangle = \lambda |\Psi\rangle.$$  

(29)

Thus, we recognize that $\Theta_{2}$ characterizes the extent to which $\Delta A^{2} + \Delta B^{2}$ deviates from $|\langle [A, B] \rangle|$. It is worth noting that the above explanation does not depend on extra properties of $|\Psi^{\perp}\rangle$ except for $\langle \Psi | \Psi^{\perp} \rangle = 0$, which in turn leads to the uncertainty inequalities (11) and (14).

III. QUBIT SYSTEM AS AN ILLUSTRATION

As the most commonly used building blocks for quantum information processing, qubit systems have played an irreplaceable role not only in theoretical analysis but also in experimental tests due to its unique properties. Therefore, it would be of great interest to evaluate the performance of these new uncertainty relations and to
can assume that $A$ and $B$ lie in the $x - y$ plane with loss of generality, that is
\begin{align}
A &= \cos \phi \sigma_x + \sin \phi \sigma_y, \\
B &= \sin \phi \sigma_x + \cos \phi \sigma_y,
\end{align}
where the angle between $A$ and $B$ is entirely characterized by the parameter $\phi$.

First, it is easy to verify that the identities (30) and (31) indeed hold for arbitrary pure states $|\Psi\rangle$ by utilizing $|\Psi^\perp\rangle\langle\Psi^\perp| = \frac{1}{2} (I - r^* \cdot \vec{\sigma})$. In particular, we have
\begin{align}
W(\Psi) &= \pm i \langle [A, B] \rangle + \langle |\Psi| A \pm i B |\Psi^\perp| \rangle^2 \\
&= 1 + \cos^2 \theta - \sin^2 \theta \sin 2\phi \sin 2\phi \\
&= 1 - |\vec{a} \cdot \vec{b}|.
\end{align}

Alternatively, we can prove in Bloch formulism that the above inequality indeed provides a state-independent lower bound for the quadratic functional $W(\Psi) = \Delta A^2 + \Delta B^2$ by using the parallelogram law (see Appendix B)
\begin{align}
W(\Psi) &\geq 1 - |\vec{a} \cdot \vec{b}| = 2(1 - c^2),
\end{align}
where $c = \max_{i,j} |\langle a_i | b_j \rangle|$ and $\{ |a_i\rangle \}$ $\{ |b_j\rangle \}$ are the corresponding eigenvectors of $A$ ($B$). Note that $c$ is the most common and important quantity in the formulation of entropic uncertainty relations (43).

Since the inequalities (30) and (31) are saturated for any single-qubit pure state, then we focus on the performance of the inequality (30) comparing with the RUR or SUR.

We notice that reformulation by normalization turns out to be a relatively reasonable way to compare different types of uncertainty relations, e.g., dividing both sides of the inequalities by their own lower bound (33) (44). According to this line of thought, we can define the following two functionals
\begin{align}
U_1(\theta, \phi, \psi) &= \frac{\Delta A^2 \Delta B^2}{||[A, B]/2||^2}, \\
U_2(\theta, \phi, \psi) &= \frac{\Delta A^2 + \Delta B^2}{||\Psi^\perp A + B |\Psi^\perp||^2/2}.
\end{align}

Therefore, the performances (or tightnesses) of uncertainty relations is to compare the left hand sides of the inequalities with the uniformly normalized lower bound 1. In our notation, we have
\begin{align}
U_1 &= \frac{[1 - \sin^2 \theta \cos^2 (\varphi - \phi)] [1 - \sin^2 \theta \sin^2 (\varphi + \phi)]}{\cos^2 \theta \cos^2 2\phi}, \\
U_2 &= \frac{2 - \sin^2 \theta (1 + \sin 2\varphi \sin 2\phi)}{(1 + \sin 2\phi) [1 - \sin^2 \theta (1 + \sin 2\varphi)/2].}
\end{align}

We first focus on the case $\phi = 0$ where two observables $A = \sigma_x$ and $B = \sigma_y$ are complementary to each other. Recall that the associated eigenvectors of the Pauli matrices are mutually unbiased bases of $\mathbb{C}^2$. In Fig. 1.
we show the contour plots of $U_1(\phi = 0)$ and $U_2(\phi = 0)$ as a function of polar angle $\theta$ and azimuthal angle $\varphi$. We can easily check that an equality $U_1 = 1$ holds for $\theta = 0, \pi$ and arbitrary $\varphi$ or arbitrary $\theta$ and $\varphi = n\pi/2$ ($n$ is an integer and notice the symmetry of the function $U_1$). When $\theta \to \pi/2$, $U_1$ diverges since the denominator of $U_1$ approaches 0 near this critical region. Meanwhile, $U_2 = 1$ is fulfilled for $\theta = \pi/2$ and $\varphi = 3\pi/4$ such that $|\Psi = 1/\sqrt{2}(|0\rangle + e^{3\pi/4}|1\rangle)$ is one of the eigenvectors of $A - B = \sigma_x - \sigma_y$, while $U_2$ diverges for $\theta = \pi/2$ and $\varphi = \pi/4$ due to the fact that $\Delta O$ vanishes if and only if $|\Psi\rangle$ is an eigenstate of the observable $O$ (see the identity (9)).

For comparison, we also present the contour plots for the case $\phi = \pi/8$. It is evident that the structure of $U_1(\phi = \pi/8)$ is greatly different from that of $U_1(\phi = 0)$, but on the contrary $U_2$ almost remains unchanged. Note that generally $A - B = (\cos \varphi - \sin \varphi)(\sigma_x - \sigma_y)$, so that the condition for convergence or divergence of $U_2$ is independent of the value of $\phi$. Indeed, we can also interpret this result intuitively by noting that $\phi$ only appears in an overall multiplicative factor of the denominator of $U_2$ (see Eq. (44)). Therefore, in order to neatly avoid the divergence of $U_2$, we can reformulate the lower bound $L_2$ as

$$L_2' = \max\{L_2, L_3\}.$$  

(45)

For the sake of completeness, we additionally have plotted the corresponding uncertainty function $U_1$ for the SUR and it turns out that $U_1$ never varies and is identically equal to unity, which means that the equality of the SUR always holds for arbitrary pure states ($|\vec{r}| = 1$). In fact, we have the following identity

$$\Upsilon(A, B, \rho) = \left[1 - (\vec{a} \cdot \vec{b})^2\right] (1 - |\vec{r}|^2) \geq 0,$$  

(46)
where we define
\[ \Upsilon(A, B, \rho) = \Delta A^2 \Delta B^2 - \frac{1}{4} |\langle C \rangle|^2 - \frac{1}{4} |\langle F \rangle|^2. \] (47)

Hence, the SUR can be employed in the domain of discrete variables to detect the mixedness of qubit states \[48].

IV. SQUEEZED STATES AND QUANTUM METROLOGY

As indicated in previous literature, the definition of squeezing or reduction of quantum fluctuations is intimately intertwined with uncertainty relations \[24]. For instance, if two arbitrary observables \( A \) and \( B \) obey the commutation relation \( [A, B] = i\mathcal{C} \) and the RUR, a state \( |\Psi \rangle \) is said to be squeezed in \( \mathcal{O} \in \{A, B\} \) if the uncertainty in \( \mathcal{O} \) satisfies the relation \[20, 22, 35, 40]
\[ \Delta \mathcal{O}^2 < |\langle C \rangle|/2. \] (48)

Following this line of thought, we can generalize this definition to the case of the variances satisfying the stronger inequality \[41], that is, one can define squeezing if
\[ \Delta \mathcal{O}^2 < |\langle C \rangle|/(2 - \Theta_1). \] (49)

Apparently, the definition \[41] will reduce to that of \[48] if \( \Theta_1 = 0 \), which means \( |\Psi \rangle \) belongs to the OISs. Alternatively, by use of the inequality \[41], another criterion of squeezing can be given as
\[ \Delta \mathcal{O}^2 < |\langle C \rangle| + \Theta_2. \] (50)

As expected, when \( \Theta_2 = 0 \) this definition also reduce to the one based on the RUR. Furthermore, some remarks are in order: (i) the definition of squeezing is not unique. An appropriate criterion should be established depending on the specific scenario where this definition makes sense \[20]; (ii) given \( A \) and \( B \), the values of \( \Theta_1 \) and \( \Theta_2 \) are determined by the choice of \( |\Psi \rangle \) \[41]. More precisely, the possible choices of \( |\Psi \rangle \) will decide the strength of the definition.

In particular, in the context of spin squeezing, various spin squeezing parameters have been proposed for different applications, which attracted increasing attention since spin squeezing has been recognized as a valuable resource for quantum metrology \[22, 23, 49, 50]. For instance, based on the definition \[48], a spin squeezing parameter can be defined with respect to two orthogonal unit vectors \( \vec{n}_1 \) and \( \vec{n}_2 \) \[24]
\[ \xi^2_H = 2(\Delta J_{n_1})^2/|\langle J_{n_2} \rangle|, \] (51)
where \( J_n = J \cdot \vec{n} \) an angular momentum operator \( J = \frac{1}{i} \sum_{l=1}^{N} \vec{\sigma}(l) \) and \( \vec{\sigma}(l) \) is the vector of Pauli matrices acting on the \( l \)th particle. When \( \xi^2_H < 1 \), the state is said to be squeezed. However, \( \xi^2_H \) may be less than 1 in coherent spin state (CSS) and this is not desirable since a CSS should not be viewed as being spin-squeezed \[22, 24, 51]. Therefore, we shift our focus to the squeezing parameter introduced by Wineland et al., which is the one directly related to interferometric sensitivity \[22]
\[ \xi^2_R = N(\Delta J_{n_1})^2/|\langle J_{n_2} \rangle|^2. \] (52)

For the scenario of optical interferometry, it has been proved that \[19, 20]
\[ \xi^2_R = \frac{N(\Delta J_{n_1})^2}{|\langle J_{n_2} \rangle|^2} \geq \frac{N}{\mathcal{F}[|\Psi\rangle, J_{n_3}]} = \chi^2, \] (53)
where \( \mathcal{F}[|\Psi\rangle, J_{n_3}] = 4(\Delta J_{n_3})^2 \) is the quantum Fisher information \[22] and \( \vec{n}_3 \) is orthogonal to both \( \vec{n}_1 \) and \( \vec{n}_2 \). The parameter \( \chi^2 < 1 \) is a sufficient condition for particle entanglement and Eq. \[53\] confirms that there exists a class of states which are entangled, \( \chi^2 < 1 \), but not spin squeezed \[13\]. In fact, by applying uncertainty relation \[1\], we can obtain a generalized version of Eq. \[53\]
\[ \xi^2_R \geq \frac{\chi^2}{(1 - \Theta_1/2)^2} \geq \chi^2, \] (54)
where we choose \( A = J_{n_1}, B = J_{n_2} \) and \( [J_{n_1}, J_{n_2}] = i\mathcal{J}_{n_2} \). Hence, if we want to attain higher sensitivity (e.g., \( \xi^2_R \) as small as possible), we are supposed to choose the input state within the set of OISs \( \Theta_1 = 0 \) \[54\].

V. CONCLUSIONS

In this work, we construct and formulate two quantum uncertainty equalities, which hold for all pairs of incompatible observables and lead to the new uncertainty relations recently introduced by Maccone and Pati \[32\]. In fact, one can obtain a series of inequalities with hierarchical structure by retaining 1 to \( d - 2 \) terms within the set \( \{ |\Psi_k \rangle \}_{k=1}^{d} \). Remarkably, we provide an explicit interpretation lying behind the structure of these inequalities and relate them to the so-called intelligent states \[32, 37\]. As an illustration, we investigate the properties of these uncertainty inequalities in the qubit system and a state-independent bound is obtained for the sum of variances. Finally, the implication of these uncertainty relations in interferometric sensitivity is also discussed in the context of spin squeezing.

Possible generalizations of our method need to be addressed. First, here we only consider the extension of RUR, but one can also extend the SUR employing the concept of GISs \[38\], where a suitable phase factor should be introduced. For example, we can establish a strengthened version of the inequality \[1\]
\[ \Delta A^2 + \Delta B^2 \geq \sqrt{|\langle C \rangle|^2 + |\langle F \rangle|^2} + \Theta_3. \] (55)
where
\[ \Theta_3 = \frac{|\langle \Psi | A \pm i e^{i\omega} B | \Psi \rangle|^2}{\gamma}, \] (56)
\[ \gamma = e^{i\omega}, \quad \tan \omega = \langle F \rangle/\langle C \rangle. \] (57)
Moreover, we notice that Pati and Wu extended the result of [22] into the realm of weak measurement [23]. In fact, the corresponding uncertainty equality of Eq. (6) in [55] can also be constructed utilizing our approach.

Appendix A: OIS, GIS and minimum-uncertainty states

As mentioned above, the OISs and GISs are quantum states that satisfy the equality sign in the RUR and SUR, respectively. However, frequently the OISs and GISs are also termed as minimum-uncertainty states in previous literature [56]. Obviously, there is no commonly accepted name for those states and here we prefer to call the states that minimize the product functional \( U(\Psi) = \Delta A^2 \Delta B^2 \) as minimum-uncertainty states [21]. In Ref. [41], Jackiw also termed it as critical states and presented a necessary condition which must be satisfied if \( U(\Psi) \) achieves the minimum value

\[
\left( \frac{\bar{A}^2}{\Delta A^2} + \frac{\bar{B}^2}{\Delta B^2} - 2 \right) |\Psi\rangle = 0, \tag{A1}
\]

where \( \bar{O} = \langle O \rangle I \).

In fact, we can also provide the similar constraint for the sum functional \( W(\Psi) = \Delta A^2 + \Delta B^2 \) by the variational method. Considering the variation \( \langle \Psi | \rightarrow (\langle | + |\delta \Psi| ) \), we have

\[
\delta(\langle O \rangle) \approx \frac{\langle \delta \Psi | O | \Psi \rangle}{\langle \Psi | \Psi \rangle} - \frac{\langle \Psi | O | \Psi \rangle}{\langle \Psi | \Psi \rangle^2} \langle \delta \Psi | \Psi \rangle, \tag{A2}
\]

where only the first-order approximation is adopted. Therefore, the variation of the variance can be represented as

\[
\delta(\Delta O^2) = \delta(\langle O^2 \rangle - \langle O \rangle^2) = \delta(\langle O^2 \rangle) - 2(\langle O \rangle) \delta(\langle O \rangle) \approx \langle \delta \Psi | \left[ \frac{\langle O^2 \rangle - \langle O \rangle^2}{\langle \Psi | \Psi \rangle} \right] | \Psi \rangle - \Delta O^2 \frac{\langle \delta \Psi | \Psi \rangle}{\langle \Psi | \Psi \rangle} \quad \tag{A3}
\]

Note that the normalization factor \( \langle \Psi | \Psi \rangle \) plays an important role in the derivation. By choosing \( O = A, B \), the stationary condition \( \delta W(\Psi) = 0 \) can be recast as

\[
\langle \delta \Psi | (\bar{A}^2 + \bar{B}^2) | \Psi \rangle = \langle \delta \Psi | (\Delta A^2 + \Delta B^2) | \Psi \rangle. \tag{A4}
\]

For the arbitrariness of \( \langle \delta \Psi | \), it follows that

\[
(\bar{A}^2 + \bar{B}^2) | \Psi \rangle = (\Delta A^2 + \Delta B^2) | \Psi \rangle. \tag{A5}
\]

This condition defines another class of critical states for the functional \( W(\Psi) \). Furthermore, combining with the extra constraint \( \Delta A = \Delta B \), this condition reduces to a special case of Eq. (A1), which is to be expected.

Appendix B: State-independent uncertainty relation for qubit system

In this Appendix, we aim to prove the following state-independent bound

\[
W(\Psi) \geq 1 - |\bar{a} \cdot \bar{b}| = 2(1 - e^2). \tag{B1}
\]

Indeed, this relation holds for arbitrary (pure or mixed) single-qubit states. Before proceeding, we would like to present two facts to simplify our discussion: (i) \( W(\Psi) \) reaches the minimum value for pure states; (ii) we only need to consider the states whose Bloch vector \( \bar{r} \) lies within the plane spanned by \( \bar{a} \) and \( \bar{b} \). The point (i) is obvious since we have \( W(\Psi) = 2 - (\bar{a} \cdot \bar{r})^2 - (\bar{b} \cdot \bar{r})^2 \). Thus, we have

\[
\min_{|\bar{r}| \leq 1} W(\Psi) = \min_{|\bar{r}| = 1} W(\Psi). \tag{B2}
\]

In addition, if \( \bar{r} \) is not coplanar with \( \bar{a} \) and \( \bar{b} \), we have the following relation

\[
\cos \vartheta = \cos \vartheta_1 \cos \vartheta_2. \tag{B3}
\]

where \( \bar{r} \) and \( \bar{r} \perp \) denotes the angle between the two vectors and \( \bar{r} \perp \) represents the unit vector along the projection of \( \bar{r} \) on the plane spanned by \( \bar{a} \) and \( \bar{b} \). From Eq. (B3), we obtain \( |\cos \vartheta_1| \leq |\cos \vartheta| \), that is, \( (\bar{a} \cdot \bar{r})^2 \leq (\bar{a} \cdot \bar{r})^2 \). Note that the same argument applies to \( \bar{b} \). Therefore, the minimum value of \( W(\Psi) \) is attained within this plane.

Since \( |\bar{r}| = 1 \), \( W(\Psi) \) can be written as

\[
W(\Psi) = \|\bar{a} \times \bar{r}\|^2 + \|\bar{b} \times \bar{r}\|^2. \tag{B4}
\]

Moreover, the Bloch vector \( \bar{r} \) can be decomposed as

\[
\bar{r} = \alpha \frac{\bar{a} + \bar{b}}{||\bar{a} + \bar{b}||} + \beta \frac{\bar{a} - \bar{b}}{||\bar{a} - \bar{b}||}, \tag{B5}
\]
where $\alpha, \beta$ are real parameters and $\alpha^2 + \beta^2 = 1$. By using the parallelogram law in Hermitian space, we have
\[
\mathcal{W}(\Psi) = \frac{1}{2} \left\{ \|\vec{a} \times \vec{r}\|^2 + \|\vec{b} \times \vec{r}\|^2 \right\} \\
= \frac{1}{2} \left\{ \|\vec{a} + \vec{b}\|^2 + \|\vec{a} - \vec{b}\|^2 \right\}
\]
\[
= \frac{1}{2} \left\{ \|\vec{a} + \vec{b}\|^2 + \|\vec{a} - \vec{b}\|^2 \right\}
\]
Since $|\beta^2 - \alpha^2| \leq 1$, we finally obtain $\mathcal{W}(\Psi) \geq 1 - |\vec{a} \cdot \vec{b}|$.

This inequality can be rewritten as
\[
(\vec{a} \cdot \vec{r})^2 + (\vec{b} \cdot \vec{r})^2 \leq 2c^2 = 1 + |\vec{a} \cdot \vec{b}|,
\]
where $c = \max_{i,j} |\langle \alpha_i | b_j \rangle|$ and $\{ |\alpha_i \rangle \} (\{ |b_j \rangle \})$ are the corresponding eigenvectors of $A (B)$. We notice the similar bounds have been obtained in \cite{12} and \cite{57}. However, Ref. \cite{12} does not provide an explicit proof and comparing with \cite{57}, our proof is compact and straightforward.

[44] Note that in our notation $\langle\{A, B\}\rangle/2 - \langle A\rangle\langle B\rangle = \alpha_2\beta_2[\vec{a} \cdot \vec{b} - (\vec{a} \cdot \vec{r})(\vec{b} \cdot \vec{r})]$. Therefore, even when considering the SUR, this type of sharp spin observables is sufficient for illustration purposes.
