Effects of Interseeding Ladino Clover into Tall Fescue Pastures of Varying Endophyte Status on Grazing Performance of Stocker Steers

L.W. Lomas and J.L. Moyer

Summary
In 2016 and 2017, 128 yearling steers grazing tall fescue pastures were used to evaluate the effects of fescue cultivar and interseeding ladino clover on available forage, grazing gains and subsequent finishing performance. Fescue cultivars evaluated were high-endophyte ‘Kentucky 31,’ low-endophyte Kentucky 31, ‘HM4,’ and ‘MaxQ.’ In 2016, steers that grazed pastures of low-endophyte Kentucky 31, HM4, or MaxQ gained significantly more ($P < 0.05$) and produced more ($P < 0.05$) gain/a than those that grazed high-endophyte Kentucky 31 pastures. Gains of cattle that grazed low-endophyte Kentucky 31, HM4, or MaxQ were similar ($P > 0.05$). In 2017, steer gains were similar ($P > 0.05$) among all cultivars. High-endophyte Kentucky 31 pastures had more ($P < 0.05$) available forage than low-endophyte Kentucky 31, HM4, or MaxQ pastures during both years. Steer gains and gain/a were similar ($P > 0.05$) between pastures fertilized with nitrogen (N) in the spring and those interseeded with ladino clover during both 2016 and 2017. Fescue cultivar or legume treatment had little effect on finishing performance or carcass characteristics of steers grazed in 2016. Steers that grazed high-endophyte Kentucky 31 had lower ($P < 0.05$) final finishing weight and lower ($P < 0.05$) carcass weight than those that grazed low-endophyte Kentucky 31, HM4, or MaxQ.

Introduction
Tall fescue, the most widely adapted cool-season perennial grass in the United States, is grown on approximately 66 million acres. Although tall fescue is well adapted in the eastern half of the country between the temperate north and mild south, presence of a fungal endophyte results in poor performance of grazing livestock, especially during the summer. Until recently, producers with high-endophyte tall fescue pastures had two primary options for improving grazing livestock performance. One option was to destroy existing stands and replace them with endophyte-free fescue or other forages. Although it supports greater animal performance than endophyte-infected fescue, endophyte-free fescue has been shown to be less persistent under grazing pressure and more susceptible to stand loss from drought stress. In locations where high-endophyte tall fescue must be grown, the other option was for producers to adopt management strategies that reduce the negative effects of the endophyte on grazing animals, such as...
diluting the effects of the endophyte by incorporating legumes into existing pastures or providing supplemental feed. In recent years, new tall fescue cultivars have been developed with a non-toxic endophyte that provides vigor to the fescue plant without negatively affecting performance of grazing livestock. Interseeding legumes into tall fescue cultivars with the non-toxic endophyte should be an effective way of increasing gains of cattle grazing tall fescue. However, these cultivars lack the competitiveness of high-endophyte Kentucky 31 and their competitiveness with legumes could be a potential problem. Objectives of this study were to evaluate forage availability, stand persistence, and performance of stocker steers grazing tall fescue cultivars with non-toxic endophyte and high- and low-endophyte Kentucky 31 with and without ladino clover.

**Experimental Procedures**

Sixty-four mixed black yearling steers were weighed on two consecutive days and allotted to sixteen 5-acre established pastures of high-endophyte Kentucky 31 or low-endophyte Kentucky 31, HM4, or MaxQ tall fescue (4 replications per cultivar) on March 30, 2016 (535 lb) and March 28, 2017 (597 lb). ‘HM4’ and MaxQ are cultivars with a non-toxic endophyte. Two pastures of each cultivar had been interseeded with 5 lb/a of ‘Will’ ladino clover on February 22, 2016. Four steers were assigned to each pasture. Pastures without clover were fertilized with 80 lb/a of N on February 10, 2016, and February 16, 2017. All pastures were fertilized with 40 lb/a of N and P$_2$O$_5$ and K$_2$O as required by soil test on September 13, 2016 and September 11, 2017.

Pasture was the experimental unit and weight gain was the primary measurement. No implants or feed additives were used. Cattle were weighed and forage availability was measured every 28 days with a disk meter calibrated for tall fescue. Cattle were treated for internal and external parasites before being turned out to pasture and later vaccinated for protection from pinkeye. Steers had free access to commercial mineral blocks that contained 12% calcium, 12% phosphorus, and 12% salt. Four steers were removed from the study for reasons unrelated to experimental treatment and replaced with grazers to maintain equal stocking rates. Pastures were grazed continuously until November 29, 2016 (244 days) and December 6, 2017 (253 days) when steers were weighed on two consecutive days and grazing was terminated.

After the grazing period, cattle were moved to a finishing facility, implanted with Synovex-S (Zoetis, Kalamazoo, MI), and fed a diet of 80% whole-shelled corn, 15% corn silage, and 5% supplement (dry matter basis) to determine the effect of grazing treatment on subsequent finishing performance. Cattle that grazed in 2016 were fed a finishing diet for 98 days and were then slaughtered in a commercial facility, and carcass data were collected on each individual steer. Cattle that were grazed during 2017 were being finished for slaughter at the time that this report was written.

**Results and Discussion**

Grazing and finishing performance for 2016 is pooled across legume treatment and presented by tall fescue cultivar in Table 1 and pooled across fescue cultivar and presented by legume treatment in Table 2. There were no significant interactions ($P > 0.05$) between fescue cultivar and legume treatment for cattle performance. However, there was
a significant \( (P < 0.05) \) fescue cultivar \times legume interaction for average available forage dry matter (DM). Steers that grazed low-endophyte Kentucky 31, HM4, or MaxQ were heavier \( (P < 0.05) \) at the end of the grazing period, had greater \( (P < 0.05) \) grazing gain, greater \( (P < 0.05) \) daily gain, and produced greater \( (P < 0.05) \) gain/a than steers grazing high-endophyte Kentucky 31. Average available forage DM of high-endophyte Kentucky 31 pasture was greater \( (P < 0.05) \) than that of low-endophyte Kentucky 31, HM4, or MaxQ. MaxQ pasture had greater \( (P < 0.05) \) available forage DM than low-endophyte Kentucky 31. Average available forage DM of HM4 pasture was similar \( (P > 0.05) \) to that of low-endophyte Kentucky 31 and MaxQ pastures. Steer gains were similar \( (P > 0.05) \) between pastures fertilized with an additional 80 lb/a of N and those interseeded with ladino clover. Pastures with clover had less \( (P < 0.05) \) available forage DM than those without clover for all cultivars except high-endophyte Kentucky 31 where available forage DM of pastures with and without clover were similar \( (P > 0.05) \).

Fescue cultivar had no effect \( (P > 0.05) \) on finishing gain, dry matter intake, or feed:gain ratio. However, steers that had previously grazed high-endophyte Kentucky 31 had lower \( (P < 0.05) \) weight at the end of the finishing phase and lower \( (P < 0.05) \) hot carcass weight than those that had previously grazed low-endophyte Kentucky 31, HM4, or MaxQ. The weight differential between cattle that grazed high-endophyte Kentucky 31 and those that grazed low-endophyte Kentucky 31, HM4, or MaxQ was similar at the end of the grazing phase (156 lb) and the end of the finishing phase (155 lb). Therefore, the weight advantage of cattle that grazed low-endophyte Kentucky 31, HM4, or MaxQ occurred during the grazing phase and was maintained during the finishing phase. Cattle that grazed high-endophyte Kentucky 31 did not exhibit any compensatory gain during the finishing phase. Backfat thickness of steers that grazed high-endophyte Kentucky 31 or HM4 was similar \( (P > 0.05) \) and lower \( (P < 0.05) \) than that of steers that grazed low-endophyte Kentucky 31 or MaxQ. Yield grade of steers that grazed high-endophyte Kentucky 31 was numerically lower \( (P < 0.05) \) than that of steers that grazed low-endophyte Kentucky 31 or MaxQ and similar \( (P > 0.05) \) to that of steers that grazed HM4. Fescue cultivar had no effect \( (P > 0.05) \) on ribeye area, marbling score, or percent of carcasses that graded USDA Choice. Overall gain of steers that grazed high-endophyte Kentucky 31 was lower \( (P < 0.05) \) than that of steers that grazed low-endophyte Kentucky 31, HM4, or MaxQ, and overall gain of steers that grazed low-endophyte Kentucky 31, HM4, or MaxQ was similar \( (P > 0.05) \). Legume treatment had no effect \( (P > 0.05) \) on finishing performance or carcass traits.

Grazing performance for 2017 is pooled across legume treatment and presented by tall fescue cultivar in Table 3 and pooled across fescue cultivar and presented by legume treatment in Table 4. Fescue cultivar and legume treatment had no effect \( (P > 0.05) \) on grazing performance. However, average available forage DM of high-endophyte Kentucky 31 pastures was greater \( (P < 0.05) \) than for low-endophyte Kentucky 31, HM4, or MaxQ. This was likely due to lower forage intake by cattle grazing the high-endophyte Kentucky 31 pastures. Average available forage DM of low-endophyte Kentucky 31, HM4, and MaxQ pastures were similar. Pastures fertilized with nitrogen in the spring had greater \( (P < 0.05) \) average available forage DM than those that were interseeded with ladino clover.

| Ending weight, lb        | 901                  | 1029         | 986          | 1007         |
| Gain, lb                 | 304                  | 432          | 389          | 411          |
| Daily gain, lb           | 1.20                 | 1.71         | 1.54         | 1.62         |
| Gain/a, lb               | 244                  | 346          | 311          | 328          |
| Average available forage dry matter, lb/a | 5,179a | 4,728b | 4,812b | 4,808b |

Means within a row followed by the same letter do not differ ($P < 0.05$).

Table 4. Effects of interseeding ladino clover on performance of steers grazing tall fescue pastures, Southeast Agricultural Research Center, 2017

| Item                     | Legume treatment |
|--------------------------|------------------|
|                          | No legume        | Ladino clover |
| Grazing phase (253 days) |                  |               |
| Number of head           | 32               | 32            |
| Initial weight, lb       | 597              | 597           |
| Ending weight, lb        | 951              | 1011          |
| Gain, lb                 | 354              | 414           |
| Daily gain, lb           | 1.40             | 1.64          |
| Gain/a, lb               | 283              | 331           |
| Average available forage dry matter, lb/a | 5,215a | 4,548b |

Means within a row followed by the same letter do not differ ($P < 0.05$).
