On finite induced crossed modules,
and the homotopy 2-type of mapping cones

Abstract

Results on the finiteness of induced crossed modules are proved both algebraically and topologically. Using the Van Kampen type theorem for the fundamental crossed module, applications are given to the 2-types of mapping cones of classifying spaces of groups. Calculations of the cohomology classes of some finite crossed modules are given, using crossed complex methods.

Introduction

Crossed modules were introduced by J.H.C. Whitehead in [29]. They form a part of what can be seen as his programme of testing the idea of extending to higher dimensions the methods of combinatorial group theory of the 1930’s, and of determining some of the extra structure that was necessary to model the geometry. Other papers of Whitehead of this era show this extension of combinatorial group theory tested in different directions.

In this case he was concerned with the algebraic properties satisfied by the boundary map

$$\partial : \pi_2(X, A) \to \pi_1(A)$$

of the second relative homotopy group, together with the standard action on it of the fundamental group $\pi_1(A)$. This is the fundamental crossed module of the pair $(X, A)$. In order to determine the second homotopy group of a $CW$-complex, he formulated and proved the following theorem for this structure:

**Theorem W** Let $X = A \cup \{e^2\}$ be obtained from the connected space $A$ by attaching 2-cells. Then the second relative homotopy group $\pi_2(X, A)$ may be described as the free crossed $\pi_1(A)$-module on the 2-cells.

The proof in [30] uses transversality and knot theory ideas from the previous papers [28, 29]. See [5] for an exposition of this proof. Several other proofs are available. The survey by
Brown and Huebschmann [12], and the book edited by Hog-Angeloni, Metzler and Sieradski [20], give wider applications.

The paper of Mac Lane and Whitehead [25] uses Theorem W to show that the 2-dimensional homotopy theory of pointed, connected CW-complexes is completely modelled by the theory of crossed modules. This is an extra argument for regarding crossed modules as 2-dimensional versions of groups.

One of our aims is the explicit calculation of examples of the crossed module

$$\pi_2(A \cup \Gamma V, A) \to \pi_1(A)$$

of a mapping cone, when $\pi_1(V), \pi_1(A)$ are finite. The key to this is the 2-dimensional Van Kampen Theorem (2-VKT) proved by Brown and Higgins in [9]. This implies a generalisation of Theorem W, namely that the crossed module (1) is induced from the identity crossed module $\pi_1(V) \to \pi_1(V)$ by the morphism $\pi_1(V) \to \pi_1(A)$.

Presentations of induced crossed modules are given in [9], and from these we prove a principal theorem (Theorem 2.1), that crossed modules induced from finite crossed modules by morphisms of finite groups are finite. We also use topological methods to show that induced crossed modules of finite $p$-groups are also finite $p$-groups. These results give a new range of finite crossed modules.

Sequels discuss crossed modules induced by a normal inclusion [16], and calculations obtained using a group theory package [17].

The origin of the 2-VKT was the idea of extending to higher dimensions the notion of the fundamental groupoid, as suggested in 1967 in [8]. This led to the discovery of the relationship of 2-dimensional groupoids to crossed modules, in work with Spencer [14]. This relationship reinforces the idea of ‘higher dimensional group theory’, and was essential for the proof of the 2-VKT for the fundamental crossed module. In view of the results of Mac Lane and Whitehead, and of methods of classifying spaces of crossed modules by Loday [24] and Brown and Higgins [11] (see section 3), the 2-VKT allows for the explicit computation of some homotopy 2-types, in the form of the crossed modules which model them.

In some cases, the Postnikov invariant of these 2-types can be calculated, as the following example shows.

**Corollary 5.5** Let $C_n$ denote the cyclic group of order $n$, and let $BC_n$ denote its classifying space. The first Postnikov invariant of the mapping cone $BC_n \cup \Gamma BC_n$ is a generator of a cyclic group of order $n$, namely the cohomology group $H^3(C_n, A_n)$, where $A_n$ is a particular cyclic $C_n$-module.

The method used for the calculation of the cohomology class here is also of interest, since it involves a small free crossed resolution of the cyclic group of order $n$ in order to construct an explicit 3-cocycle corresponding to the crossed module. This indicates a wider possibility of using crossed resolutions for explicit calculations. It is also related to Whitehead’s use of what he called in [30] ‘homotopy systems’, and which are simply free crossed complexes.
1 Crossed modules and induced crossed modules

In this section, we recall the definition of induced crossed modules, and of results of \[9\] on presentations of induced crossed modules. We then give some basic examples of these.

Recall that a crossed module is a morphism of groups \(\mu : M \to P\) together with an action \((m, p) \mapsto m^p\) of \(P\) on \(M\) satisfying the two axioms

- CM1) \(\mu(m^p) = p^{-1}mp\)
- CM2) \(n^{-1}mn = m^{\mu n}\)

for all \(m, n \in M, p \in P\).

The category \(\mathcal{X}M\) of crossed modules has objects all crossed modules with morphisms the commutative diagrams

\[
\begin{array}{ccc}
M & \xrightarrow{\mu} & P \\
g & \downarrow & f \\
N & \xrightarrow{\nu} & Q
\end{array}
\]

in which the horizontal maps are crossed modules, and the pair \(g, f\) preserve the action in the sense that for all \(m \in M, p \in P\) we have \(g(m^p) = (gm)^f\). If \(P\) is a group, then the category \(\mathcal{X}M/P\) of crossed \(P\)-modules is the subcategory of \(\mathcal{X}M\) whose objects are the crossed \(P\)-modules and in which a morphism \(g : M \to N\) of crossed \(P\)-modules is a morphism of groups such that \(g\) preserves the action \((g(m^p) = (gm)^p\), for all \(m \in M, p \in P\), and \(\nu g = \mu\).

Standard algebraic examples of crossed modules are:

(i) an inclusion of a normal subgroup, with action given by conjugation;
(ii) the inner automorphism map \(\chi : M \to \text{Aut } M\), in which \(\chi m\) is the automorphism \(n \mapsto m^{-1}nm\);
(iii) the zero map \(M \to P\) where \(M\) is a \(P\)-module;
(iv) an epimorphism \(M \to P\) with kernel contained in the centre of \(M\).

All these yield examples of finite crossed modules. Other finite examples may be constructed from those above, the induced crossed modules of this paper and its sequel \[16\], and coproducts \[4\] and tensor products \[13, 19\] of crossed \(P\)-modules.

Further important examples of crossed modules are the free crossed modules, referred to in the Introduction, and which are rarely finite. They arise algebraically in considering identities among relations \[12\], which are non abelian forms of syzygies.

We next define pullback crossed modules. Let \(\iota : P \to Q\) be a morphism of groups. Let \(\nu : N \to Q\) be a crossed \(Q\)-module. Let \(\iota^*N \to P\) be the pullback of \(N\) by \(\iota\), so that \(\iota^*N = \{(p, n) \in P \times N | \iota p = \nu n\}\), and \(\iota^*N \to P\). Let \(P\) act on \(\iota^*N\) by \((p_1, n)^p = (p^{-1}p_1p, n^{\nu p})\). The verification of the axiom CM1) is immediate, while CM2) is proved as follows:
Let \((p, n), (p_1, n_1) \in \iota^* N\). Then
\[
(p, n)^{-1}(p_1, n_1)(p, n) = (p^{-1}p_1p, n^{-1}n_1n) = (p^{-1}p_1p, n_1^{n_1}) = (p^{-1}p_1p, n_1^{p}) = (p_1, n_1)^{\nu(p, n)}.
\]

**Proposition 1.1** The functor \(\iota^* : \mathcal{X}M/Q \rightarrow \mathcal{X}M/P\) has a right adjoint \(\iota_*\).

**Proof** This follows from general considerations on Kan extensions. \(\square\)

The universal property of induced crossed modules is the following. Let \(\mu : M \rightarrow P\), \(\gamma : C \rightarrow Q\) be crossed modules. In the diagram

\[
\begin{array}{ccc}
M & \xrightarrow{\mu} & P \\
\downarrow{\iota} & & \downarrow{\iota} \\
\iota_* M & \xrightarrow{\delta} & Q \\
\downarrow{g} & & \downarrow{\gamma} \\
C & & \\
\end{array}
\]

the pair \(\iota, \iota\) is a morphism of crossed modules such that for any crossed \(Q\)-module \(\gamma : C \rightarrow Q\) and morphism of crossed modules \(f, \iota\), there is a unique morphism \(g : \iota_* M \rightarrow C\) of crossed \(Q\)-modules such that \(g\iota = f\).

It is a consequence of this universal property that if \(M = P = F(R)\), the free group on a set \(R\), and if \(w : R \rightarrow Q\) is the restriction of \(\iota\) to the set \(R\), then \(\iota_* F(R)\) is the free crossed module on \(w\), in the sense of Whitehead [31] (see also [14, 21, 27]). Constructions of this free crossed module are given in these papers.

A presentation for induced crossed modules for a general morphism \(\iota\) is given in Proposition 8 of [3]. We will need two more particular results. The first is Proposition 9 of that paper, and the second is a direct deduction from Proposition 10.

**Proposition 1.2** If \(\iota : P \rightarrow Q\) is a surjection, and \(\mu : M \rightarrow P\) is a crossed \(P\)-module, then \(\iota_* M \cong M/[M, K]\), where \(K = \text{Ker } \iota\), and \([M, K]\) denotes the subgroup of \(M\) generated by all \(m^{-1}m^k\) for all \(m \in M, k \in K\).

The following term and notation will be used frequently. Let \(P\) be a group and let \(T\) be a set. We define the copower \(P \bar{\times} T\) to be the free product of groups \(P_t, t \in T\), each with elements \((p, t), p \in P\), and isomorphic to \(P\) under the map \((p, t) \mapsto p\). If \(Q\) is a group, then \(P \bar{\times} Q\) will denote the copower of \(P\) with the underlying set of the group \(Q\).
Proposition 1.3 If \( i : P \to Q \) is an injection, and \( \mu : M \to P \) is a crossed \( P \)-module, let \( T \) be a right transversal of \( iP \) in \( Q \). Let \( Q \) act on the copower \( M \not\lozenge T \) by the rule \((m, t)^q = (m^p, u)\), where \( p \in P, u \in T \), and \( tq = (ip)u \). Let \( \delta : M \not\lozenge T \to Q \) be defined by \((m, t) \mapsto t^{-1}(1 \mu m)t\). Let \( S \) be a set of generators of \( M \) as a group, and let \( S^P = \{x^p : x \in S, p \in P\} \). Then

\[ \iota_s M = (M \not\lozenge T)/R \]

where \( R \) is the normal closure in \( M \not\lozenge T \) of the elements

\[ \langle (r, t), (s, u) \rangle = (r, t)^{-1}(s, u)^{-1}(r, t)(s, u)^{\delta(r, t)} \quad (r, s \in S^P, t, u \in T). \]

Proof Let \( N = M \not\lozenge T \). Proposition 10 of [9] yields that \( \iota_s M \) is the quotient of \( N \) by the subgroup \( \langle N, N \rangle \) generated by \( \langle n, n_1 \rangle = n^{-1}n_1^{-1}nn_1^b, n, n_1 \in N \), and which is called in [12] the Peiffer subgroup of \( N \). Now \( N \) is generated by the set \( (S^P, T) = \{(s^p, t) : s \in S, p \in P, t \in T\} \), and this set is \( Q \)-invariant since \((s^p, t)^q = (s^{p'}, u)\) where \( u \in T, p' \in P \) satisfy \( tq = (ip')u \). It follows from Proposition 3 of [12] that \( \langle N, N \rangle \) is the normal closure of the set \( \langle (S^P, T), (S^P, T) \rangle \) of basic Peiffer commutators. \( \square \)

Example 1.4 The dihedral crossed module. We show how this works out in the following case, which exhibits a number of typical features. We let \( Q \) be the dihedral group \( D_n \) with presentation \( \langle x, y : x^n = y^2 = xyxy = 1 \rangle \), and let \( M = P \) be the cyclic subgroup \( C_2 \) of order 2 generated by \( y \). Let \( C_n = \{0, 1, 2, \ldots, n - 1\} \) be the cyclic group of order \( n \). A right transversal \( T \) of \( C_2 \) in \( D_n \) is given by the elements \( x^i, i \in C_n \). Hence \( \iota_s C_2 \) has a presentation with generators \( a_i = (y, x^i), i \in C_n \), and relations given by \( a_i^2 = 1, i \in C_n \), together with the Peiffer relations. Now \( \delta a_i = x^{-i}yx^i = yx^{2i} \). Further the action is given by \( (a_i)^x = a_{i+1}, (a_i)^y = a_{n-i} \). Hence \( (a_i)^{ba_j} = a_{2j-i} \), so that the Peiffer relations are \( a_ja_i a_j = a_{2j-i} \). It is well known that we now have a presentation of the dihedral group \( D_n \), in which we get the standard presentation \( \langle u, v : u^n = v^2 = uvuv = 1 \rangle \) by setting \( u = a_0 a_1, v = a_0 \), so that \( u^i = a_0 a_i \). Then

\[ \delta u = x^2, \delta v = y, \]

so that \( y \) acts on \( \iota_s C_2 \) by conjugation by \( v \). However \( x \) acts by

\[ u^x = u, v^x = vu. \]

Note that this is consistent with the crossed module axiom CM2) since

\[ v^x^2 = (vu)^x = vuu = u^{-1}vu. \]

We call this crossed module the dihedral crossed module. It follows from these formulae that \( \delta \) in the induced crossed module \( \delta : D_n \to D_n \) is an isomorphism if \( n \) is odd, and has kernel and cokernel isomorphic to \( C_2 \) if \( n \) is even. In particular, if \( n \) is even, then by results of section [3] \( \pi_2(BD_n \cup \Gamma BC_2) \) can be regarded as having one non-trivial element represented by \( u^{n/2} \).
Corollary 1.5 Assume $\iota : P \to Q$ is injective. If $M$ has a presentation as a group with $g$ generators and $r$ relations, the set of generators of $M$ is $P$-invariant, and $n = [Q : \iota \mu(M)]$, then $\iota_*M$ has a presentation with $gn$ generators and $rn + g^2n(n - 1)$ relations.

Another corollary determines induced crossed modules under some abelian conditions. This result has useful applications. If $M$ is an abelian group, or $P$-module, and $T$ is a set we define the copower of $M$ with $T$, written $M \oplus T$, to be the sum of copies of $M$ one for each element of $T$.

Corollary 1.6 Let $\mu : M \to P$ be a crossed $P$-module and $\iota : P \to Q$ a monomorphism of groups such that $M$ is abelian and $\iota \mu(M)$ is normal in $Q$. Then $\iota_*M$ is abelian and as a $Q$-module is just the induced $Q$-module in the usual sense.

Proof We use the result and notation of Proposition 1.3. Note that if $u, t \in T$ and $r \in S$ then $u\delta(r, t) = ut^{-1}(\iota \mu t) = (\iota \mu)ut^{-1}t = (\iota \mu)m u$ for some $m \in M$, by the normality condition. The Peiffer commutator given in Proposition 1.3 can therefore be rewritten as

$$(r, t)^{-1}(s, u)^{-1}(r, t)(s, u)^{\delta(r, t)} = (r^{-1}, t)(s, u)^{-1}(r, t)(s^m, u).$$

Since $M$ is abelian, $s^m = s$. Thus the basic Peiffer commutators reduce to ordinary commutators. Hence $\iota_*M$ is the copower $M \oplus T$, and this, with the given action, is the usual presentation of the induced $Q$-module. □

Example 1.7 Let $M = P = Q$ be the infinite cyclic group, which we write $\mathbb{Z}$, and let $\iota : P \to Q$ be multiplication by 2. Then $\iota_*M \cong \mathbb{Z} \oplus \mathbb{Z}$, and the action of a generator of $Q$ on $\iota_*M$ is to switch the two copies of $\mathbb{Z}$. This result could also be deduced from well known results on free crossed modules. However, our results show that we get a similar conclusion simply by replacing each $\mathbb{Z}$ in the above by for example $C_4$, and this fact is new.

2 On the finiteness of induced crossed modules

In this section we give an algebraic proof that a crossed module induced from a finite crossed module by a morphism with finite cokernel is also finite. In a later section we will prove a slightly less general result, but by topological methods which will also yield results on the preservation of the Serre class of a crossed module under the inducing process.

Theorem 2.1 Let $\mu : M \to P$ be a crossed module and let $\iota : P \to Q$ be a morphism of groups. Suppose that $M$ and the index of $\iota(P)$ in $Q$ are finite. Then the induced crossed module $\iota_*M$ is finite.
\textbf{Proof} Factor the morphism \( \iota : P \to Q \) as \( \tau \sigma \) where \( \tau \) is injective and \( \sigma \) is surjective. Then \( \iota_* M \) is isomorphic to \( \tau_* \sigma_* M \). It is immediate from Proposition 1.2 that if \( M \) is finite then so also is \( \sigma_* M \). So it is enough to assume that \( \iota \) is injective, and in fact we assume it is an inclusion.

Let \( T \) be a right transversal of \( P \) in \( Q \). Then there is a function \((\xi, \eta) : T \times Q \to P \times T\) determined by the equation \( tq = \xi(t, q)\eta(t, q) \) for all \( t \in T, q \in Q \). Let \( Y = \copower T \) be the copower of \( M \) and \( T \), and let \( \delta : Y \to Q \) and the action of \( Q \) on \( Y \) be as in Proposition 1.3. A basic Peiffer relation is then of the form

\[
(m, t)(n, u) = (n, u)(m^{\xi(t,u^{-1}(\mu m)u)}, \eta(t, u^{-1}\mu(m)u))
\]

where \( m, n \in M, t, u \in T \).

We now assume that the finite set \( T \) has been given the total order \( t_1 < t_2 < \ldots < t_l \). An element of \( Y \) may be represented as a reduced word \((m_1, u_1)(m_2, u_2)\ldots(m_e, u_e)\).

Such a word is said to be \textit{ordered} if \( u_1 < u_2 < \ldots < u_e \) in the given order on \( T \).

\textbf{Claim:} There is an algorithm which, applying the Peiffer relations (2) with \( u < t \) to the reduced word (3), yields an ordered word.

This is proved as an application of a purely combinatorial result in [15].

Let \( Z = M_{t_1} \times M_{t_2} \times \ldots \times M_{t_l} \) be the product of the sets \( M_{t_i} = M \times \{t_i\} \). Then the Claim implies that there is a function \( \phi : Y \to Z \) such that the quotient morphism \( Y \to \iota_* M \) factors through \( \phi \). But \( Z \) is finite. It follows that \( \iota_* M \) is finite. \( \square \)

\section{Topological applications}

As explained in the Introduction, the fundamental crossed module functor \( \Pi_2 \) assigns a crossed module \( \partial : \pi_2(X, A) \to \pi_1(A) \) to any base pointed pair of spaces \((X, A)\). We will use the following consequence of Theorem C of [9], which is a 2-dimensional Van Kampen type theorem for this functor.

\textbf{Theorem 3.1} (9, Theorem D) Let \((B, V)\) be a cofibred pair of spaces, let \( f : V \to A \) be a map, and let \( X = A \cup_f B \). Suppose that \( A, B, V \) are path-connected, and the pair \((B, V)\) is
1-connected. Then the pair \((X, A)\) is 1-connected and the diagram

\[
\begin{array}{ccc}
\pi_2(B, V) & \xrightarrow{\delta} & \pi_1(V) \\
\downarrow{\epsilon} & & \downarrow{\lambda} \\
\pi_2(X, A) & \xrightarrow{\delta'} & \pi_1(A)
\end{array}
\]

presents \(\pi_2(X, A)\) as the crossed \(\pi_1(A)\)-module \(\lambda_*(\pi_2(B, V))\) induced from the crossed \(\pi_1(V)\)-module \(\pi_2(B, V)\) by the group morphism \(\lambda : \pi_1(V) \to \pi_1(A)\) induced by \(f\).

As pointed out earlier, in the case \(P\) is a free group on a set \(R\), and \(\mu\) is the identity, then the induced crossed module \(\nu_* P\) is the free crossed \(Q\)-module on the function \(\iota R : R \to Q\). Thus Theorem 3.1 implies Whitehead’s Theorem W of the Introduction. A considerable amount of work has been done on this case, because of the connections with identities among relations, and methods such as transversality theory and “pictures” have proved successful ([12, 27]), particularly in the homotopy theory of 2-dimensional complexes [20]. However, the only route so far available to the wider geometric applications of induced crossed modules is Theorem 3.1. We also note that this Theorem includes the relative Hurewicz Theorem in this dimension, on putting \(A = \Gamma V\), and \(f : V \to \Gamma V\) the inclusion.

We will apply this Theorem 3.1 to the classifying space of a crossed module, as defined by Loday in [24] or Brown and Higgins in [11]. This classifying space is a functor \(B\) assigning to a crossed module \(M = (\mu : M \to P)\) a pointed \(CW\)-space \(BM\) with the following properties:

3.2 The homotopy groups of the classifying space of the crossed module \(\mu : M \to P\) are given by

\[
\pi_i(B(M \to P)) \cong \begin{cases} 
\text{Coker } \mu & \text{for } i = 1 \\
\text{Ker } \mu & \text{for } i = 2 \\
0 & \text{for } i > 2
\end{cases}
\]

3.3 The classifying space \(B(1 \to P)\) is the usual classifying space \(BP\) of the group \(P\), and \(BP\) is a subcomplex of \(B(M \to P)\). Further, there is a natural isomorphism of crossed modules

\[
\Pi_2(B(M \to P), BP) \cong (M \to P).
\]

3.4 If \(X\) is a reduced \(CW\)-complex with 1-skeleton \(X^1\), then there is a map

\[
X \to B(\Pi_2(X, X^1))
\]

inducing an isomorphism of \(\pi_1\) and \(\pi_2\).
It is in these senses that it is reasonable to say, as in the Introduction, that crossed modules model all pointed homotopy 2-types.

We now give two direct applications of Theorem 3.1.

**Corollary 3.5** Let \( \mu : M \to P \) be a crossed module, and let \( \iota : P \to Q \) be a morphism of groups. Let \( \beta : BP \to B(M \to P) \) be the inclusion. Consider the pushout

\[
\begin{array}{ccc}
BP & \xrightarrow{\beta} & B(M \to P) \\
\downarrow B\iota & & \downarrow \\
BQ & \xrightarrow{\beta'} & X.
\end{array}
\]

(4)

Then the fundamental crossed module of the pair \( (X, BQ) \) is isomorphic to the induced crossed module \( \iota_*M \to Q \), and this crossed module determines the 2-type of \( X \).

**Proof** The first statement is immediate from Theorem 3.1. The final statement follows from results of [11], since the morphism \( Q \to \pi_1(X) \) is surjective. \(\square\)

**Remark 3.6** An interesting special case of the last corollary is when \( \mu : M \to P \) is an inclusion of a normal subgroup, since then \( B(M \to P) \) is of the homotopy type of \( B(P/M) \). So we have determined the 2-type of a homotopy pushout

\[
\begin{array}{ccc}
BP & \xrightarrow{Bp} & BR \\
\downarrow B\iota & & \downarrow \\
BQ & \xrightarrow{p'} & X
\end{array}
\]

in which \( p : P \to R \) is surjective.

We write \( \Gamma V \) for the cone on a space \( V \).

**Corollary 3.7** Let \( \iota : P \to Q \) be a morphism of groups. Then the fundamental crossed module \( \Pi_2(BQ \cup_{B\iota} \Gamma BP, BQ) \) is isomorphic to the induced crossed module \( \iota_*P \to Q \).

## 4 Finiteness theorems by topological methods

The aim of this section is to show that the property of being a finite \( p \)-group is preserved by the process of induced crossed modules. We use topological methods.

An outline of the method is as follows. Suppose that \( Q \) is a finite \( p \)-group. To prove that \( \iota_*M \) is a finite \( p \)-group, it is enough to prove that \( \text{Ker } (\iota_*M \to Q) \) is a finite \( p \)-group. But this kernel is the second homotopy group of the space \( X \) of the pushout (4), and so is
also isomorphic to the second homology group of the universal cover \( \widetilde{X} \) of \( X \). In order to apply the homology Mayer-Vietoris sequence to this universal cover, we need to show that it may be represented as a pushout, and we need information on the homology of the spaces determining this pushout. So we start with the necessary information on covering spaces.

We work in the convenient category \( \text{TOP} \) of weakly Hausdorff \( k \)-spaces \([23]\). Let \( \alpha : \widetilde{X} \to X \) be a map of spaces. In the examples we will use, \( \alpha \) will be a covering map. Then \( \alpha \) induces a functor

\[
\alpha^* : \text{TOP}/X \to \text{TOP}/\widetilde{X}.
\]

It is known that \( \alpha \) has a right adjoint and so preserves colimits \([2, 1, 23]\).

For regular spaces, the pullback of a covering space in the above category is again a covering space. These results enable us to identify a covering space of an adjunction space as an adjunction space obtained from the induced covering spaces.

If further, \( \alpha \) is a covering map, and \( X \) is a CW-complex, then \( \widetilde{X} \) may be given the structure of a CW-complex \([26]\).

We also need a special case of the basic facts on the path components and fundamental group of induced covering maps \([7, 8, 26]\). Given the following pullback

\[
\begin{array}{ccc}
\hat{A} & \longrightarrow & \tilde{X} \\
\alpha' \downarrow & & \downarrow \alpha \\
A & \longrightarrow & X \\
\end{array}
\]

and points \( a \in A, \, \tilde{x} \in \tilde{X} \) such that \( fa = \alpha \tilde{x} \), in which \( \alpha \) is a universal covering map and \( X, A, \tilde{X} \) are path connected, then there is a sequence

\[
1 \to \pi_1(\hat{A}, (a, \tilde{x})) \to \pi_1(A, a) \xrightarrow{f_*} \pi_1(X, fa) \to \pi_0(\hat{A}) \to 1. \tag{5}
\]

This sequence is exact in the sense of sequences arising from fibrations of groupoids \([7]\), which involves an operation of the fundamental group \( \pi_1(X, fa) \) on the set \( \pi_0(\hat{A}) \) of path components of \( \hat{A} \). It follows that the fundamental group of \( \hat{A} \) is isomorphic to \( \text{Ker} \, f_* \), and that \( \pi_0(\hat{A}) \) is bijective with the set of cosets \( (\pi_1(X, fa)) / (f_* \pi_1(A, a)) \). It is also clear that the covering \( \hat{A} \to A \) is regular and that all the components of \( \hat{A} \) are homeomorphic.

Let \( \mathcal{M} \) be the crossed module \( \mu : M \to P \) and let \( \iota : P \to Q \) be a morphism of groups. Let

\[
X = BQ \cup_{B\iota} BM
\]

as in diagram \([4]\). Let \( \alpha : \tilde{X} \to X \) be the universal covering map, and let \( \hat{B}Q, \, \hat{B}M, \, \hat{B}P \) be the pullbacks of \( \tilde{X} \) under the maps \( BQ \to X, \, BM \to X, \, BP \to X \). Then we may write

\[
\tilde{X} \cong \hat{B}Q \cup_{\hat{B}\iota} \hat{B}M, \tag{6}
\]

by the results of section \([3]\).
From the exact sequence (5) we obtain the following exact sequences, in which \( \pi_1 X \cong Q \ast_P (P/\mu M) \):

\[
\begin{align*}
1 & \to \pi_1(\widehat{BQ}) \to Q \to Q \ast_P (P/\mu M) \to 1, \\
1 & \to \pi_1(\widehat{BM}) \to P/\mu M \to Q \ast_P (P/\mu M) \to \pi_0 \widehat{BM} \to 1, \\
1 & \to \pi_1(\widehat{BP}) \to P \to Q \ast_P (P/\mu M) \to \pi_0 \widehat{BP} \to 1.
\end{align*}
\]

**Proposition 4.1** Under the above situation, let the groups \( \pi_1(\widehat{BP}), \pi_1(\widehat{BM}), \pi_1(\widehat{BQ}) \) be denoted by \( P', M', Q' \) respectively, and let \( B'M' \) denote a component of \( \widehat{BM} \). Then there is an exact sequence

\[
H_2(P') \oplus \pi_0 \widehat{BP} \to (H_2(BM') \oplus \pi_0 \widehat{BM}) \oplus H_2(Q') \to \pi_2(X) \to \\
\to H_1(P') \oplus \pi_0 \widehat{BP} \to (H_1(M') \oplus \pi_0 \widehat{BM}) \oplus H_1(Q') \to 0.
\]

**Proof** This is immediate from the Mayer-Vietoris sequence for the pushout (3) and the fact that \( H_2(\overline{X}) \cong \pi_2(X) \).

**Corollary 4.2** If \( \iota : P \to Q \) is the inclusion of a normal subgroup, and \( X = BQ \cup_{B\iota} \Gamma BP \), then \( \pi_2(X) \) is isomorphic to \( H_1(P) \otimes I(Q/P) \), where \( I(G) \) denotes the augmentation ideal of a group \( G \).

Note that this agrees with the result of Corollary 1.8 of [16], in which the induced crossed module itself is computed via the use of coproducts of crossed \( P \)-modules.

**Corollary 4.3** Let \( \mu : M \to P \) be a crossed module and let \( \iota : P \to Q \) be a morphism of groups. If \( M, P \) and \( Q \) are finite \( p \)-groups, then so also is the induced crossed module \( \iota_* M \).

**Proof** It is standard that the (reduced) homology groups of a finite \( p \)-group are finite \( p \)-groups. The same applies to the reduced homology of the classifying space of a crossed module of finite \( p \)-groups. The latter may be proved using the spectral sequence of a covering, and Serre \( C \) theory, as in Chapters IX and X of [21]. In the present case, we need information only on \( H_2(B(M \to P)) \), and some of its connected covering spaces, and this may be deduced from the exact sequence due to Hopf

\[
H_3K \to H_3G \to (\pi_2K) \otimes_{\mathbb{Z}G} \mathbb{Z} \to H_2K \to H_2G \to 0
\]

for any connected space \( K \) with fundamental group \( G \) (see for example Exercise 6 on p.175 of [8]). Proposition 4.1 shows that \( \ker (\iota_* (M) \to Q) \cong \pi_2(X) \) is a finite \( p \)-group. Since \( Q \) is a finite \( p \)-group, it follows that \( \iota_* M \) is a finite \( p \)-group.

Note that these methods extend also to results on the Serre class of an induced crossed module, which we leave the reader to formulate.
5 Cohomology classes

Recall [22, 3] that if \( G \) is a group and \( A \) is a \( G \)-module, then elements of \( H^3(G, A) \) may be represented by equivalence classes of crossed sequences

\[
0 \to A \to M \xrightarrow{\mu} P \to G \to 1,
\]

namely exact sequences as above such that \( \mu : M \to P \) is a crossed module. The equivalence relation between such crossed sequences is generated by the basic equivalences, namely the existence of a commutative diagram of morphisms of groups as follows

\[
\begin{array}{ccccccc}
0 & \to & A & \xrightarrow{1} & M & \xrightarrow{\mu} & P & \xrightarrow{1} & G & \to & 1 \\
& & \downarrow{1} & & \downarrow{f} & & \downarrow{g} & & \downarrow{1} \\
0 & \to & A & \xrightarrow{1} & M' & \xrightarrow{\mu'} & P' & \xrightarrow{1} & G & \to & 1 \\
\end{array}
\]

such that \( f, g \) form a morphism of crossed modules. Such a diagram is called a morphism of crossed sequences.

The zero cohomology class is represented by the crossed sequence

\[
0 \to A \xrightarrow{1} A \xrightarrow{0} G \xrightarrow{1} G \to 1,
\]

which we sometimes abbreviate to

\[
A \xrightarrow{0} G.
\]

In a similar spirit, we say that a crossed module \( \mu : M \to P \) represents a cohomology class, namely an element of \( H^3(\text{Coker } \mu, \text{Ker } \mu) \).

Example 5.1 Let \( C_{n^2} \) denote the cyclic group of order \( n^2 \), written multiplicatively, with generator \( u \). Let \( \gamma_n : C_{n^2} \to C_{n^2} \) be given by \( u \mapsto u^n \). This defines a crossed module, with trivial operations. This crossed module represents the trivial cohomology class in \( H^3(C_n, C_n) \), in view of the morphism of crossed sequences

\[
\begin{array}{ccccccc}
0 & \to & C_n & \xrightarrow{1} & C_n & \xrightarrow{0} & C_n & \xrightarrow{1} & C_n & \to & 0 \\
& & \downarrow{1} & & \downarrow{\lambda} & & \downarrow{\lambda} & & \downarrow{1} \\
0 & \to & C_n & \xrightarrow{1} & C_{n^2} & \xrightarrow{\gamma_n} & C_{n^2} & \xrightarrow{1} & C_n & \to & 0 \\
\end{array}
\]

where if \( t \) is the generator of the top \( C_n \), then \( \lambda(t) = u^n \).

Example 5.2 We show that the dihedral crossed module \( \partial : D_n \to D_n \) represents the trivial cohomology class. This is clear for \( n \) odd, since then \( \partial \) is an isomorphism. For \( n \) even, we
simply construct a morphism of crossed sequences as in the following diagram

\[
\begin{array}{cccccccc}
0 & \rightarrow & C_2 & \xrightarrow{1} & C_2 & \rightarrow & C_2 & \rightarrow & 0 \\
\downarrow & \cong & \downarrow f_2 & & \downarrow f_1 & & \downarrow & & \downarrow \\
0 & \rightarrow & C_2 & \rightarrow & D_n & \xrightarrow{\partial} & D_n & \rightarrow & C_2 & \rightarrow & 0
\end{array}
\]

where if \( t \) denotes the non trivial element of \( C_2 \) then \( f_1(t) = x, f_2(t) = u^{n/2} \). Just for interest, we leave it to the reader to prove that there is no morphism in the other direction between these crossed sequences.

A crossed module \( \mu : M \rightarrow P \) determines a cohomology class

\[
k_{M \rightarrow P} \in H^3(\text{Coker } \mu, \text{Ker } \mu).
\]

If \( X \) is a connected, pointed \( CW \)-complex with 1-skeleton \( X^1 \), then the class

\[
k^3_X \in H^3(\pi_1 X, \pi_2 X)
\]

of the crossed module \( \Pi_2(X, X^1) \) is called the first Postnikov invariant of \( X \). This class is also represented by \( \Pi_2(X, A) \) for any connected subcomplex \( A \) of \( X \) such that \( (X, A) \) is 1-connected and \( \pi_2(A) = 0 \). It may be quite difficult to determine this Postnikov invariant from a presentation of this last crossed module, and even the meaning of the word “determine” in this case is not so clear. There are practical advantages in working directly with the crossed module, since it is an algebraic object, and so it, or families of such objects, may be manipulated in many convenient and useful ways. Thus the advantages of crossed modules over the corresponding 3-cocycles are analogous to some of the advantages of homology groups over Betti numbers and torsion coefficients.

However, in work with crossed modules, and in applications to homotopy theory, information on the corresponding cohomology classes, such as their non triviality, or their order, is also of interest. The aim of this section is to give background to such a determination, and to give two example of finite crossed modules representing non trivial elements of the corresponding cohomology groups.

The following general problem remains. If \( G, A \) are finite, where \( A \) is a \( G \)-module, how can one characterise the subset of \( H^3(G, A) \) of elements represented by finite crossed modules? This subset is a subgroup, since the addition may be defined by a sum of crossed sequences, of the Baer type. (An exposition of this is given by Danas in \[18\].) It might always be the whole group.

The natural context in which to show how a crossed sequence gives rise to a 3-cocycle is not the traditional chain complexes with operators but that of crossed complexes \[22\]. We explain how this works here. For more information on the relations between crossed complexes and the traditional chain complexes with operators, see \[10\].
Recall that a free crossed resolution of the group $G$ is a free aspherical crossed complex $F_\ast$ together with an epimorphism $\phi : F_1 \to G$ with kernel $\delta_2(F_2)$.

**Example 5.3** The cyclic group $C_n$ of order $n$ is written multiplicatively, with generator $t$. We give for it a free crossed resolution $F_\ast$ as follows. Set $F_1 = C_\infty$, with generator written $w$, and for $r \geq 2$ set $F_r = (C_\infty)^n$. Here for $r \geq 2$, $F_r$ is regarded as the free $C_n$-module on one generator $w_0$, and we set $w_i = (w_0)^i$. The morphism $\phi : C_\infty \to C_n$ sends $w$ to $t$, and the operation of $F_1$ on $F_r$ for $r \geq 2$ is via $\phi$.

The boundaries are given by

1. $\delta_2(w_i) = w^n$,

2. for $r$ odd, $\delta_r(w_i) = w_iw_{i+1}^{-1}$,

3. for $r$ even and greater than 2, $\delta_r(w_i) = w_0w_1\ldots w_{n-1}$.

Previous calculations show that $\delta_2$ is the free crossed $C_\infty$-module on the element $w^n \in C_\infty$. Thus $F_\ast$ is a free crossed complex. It is easily checked to be aspherical, and so is, with $\phi$, a crossed resolution of $C_n$.

Let $A$ be a $G$-module. Let $C(G,A,3)$ denote the crossed complex $C$ which is $G$ in dimension 1, $A$ in dimension 3, with the given action of $G$ on $A$, and which is 0 elsewhere, as in the following diagram

$$\cdots \to 0 \to A \to 0 \to G.$$ 

Let $(F_\ast, \phi)$ be a free crossed resolution of $G$. It follows from the discussions in [10, 11] that a 3-cocycle of $G$ with coefficients in $A$ can be represented as a morphism of crossed complexes $f : F_\ast \to C(G,A,3)$ over $\phi$. This cocycle is a coboundary if there is an operator morphism $l : F_2 \to A$ over $\phi : F_1 \to G$ such that $l\delta_3 = f_3$.

$$F_1 \xrightarrow{\delta_4} F_3 \xrightarrow{\delta_3} F_2 \xrightarrow{\delta_2} F_1$$

$$\xrightarrow{f_3} \xrightarrow{l} \xrightarrow{\phi}$$

$$0 \xrightarrow{\phi} A \xrightarrow{\phi} 0 \xrightarrow{\phi} G$$

To construct a 3-cocycle on $F_\ast$ from the crossed sequence (7), first construct a morphism of crossed complexes as in the diagram

$$F_1 \xrightarrow{f_1} F_3 \xrightarrow{f_2} F_2 \xrightarrow{f_3} A \xrightarrow{\phi} G$$

(8)
using the freeness of $F_*$ and the exactness of the bottom row. Then compose this with the morphism of crossed sequences

$$
\begin{array}{cccccccc}
0 & A & M & P & \psi & G \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
0 & A & 0 & G & 1 & G
\end{array}
$$

Hence it is reasonable to say that the morphism $f_3$ of diagram (8) is a 3-cocycle corresponding to the crossed sequence.

We now use these methods in an example.

**Theorem 5.4** Let $n \geq 2$, and let $\iota : C_n \to C_{n^2}$ denote the injection sending a generator $t$ of $C_n$ to $u^n$, where $u$ denotes a generator of $C_{n^2}$. Let $A_n$ denote the $C_n$-module which is the kernel of the induced crossed module $\partial : \iota_* C_n \to C_{n^2}$. Then $H^3(C_n, A_n)$ is cyclic of order $n$ and has as generator the class of this induced crossed module.

**Proof** Write $\mathcal{N}$ for the induced crossed module of the theorem. By Corollary 1.6 the abelian group $\iota_* C_n$ is the product $V = (C_n)^n$. As a $C_n$-module it is cyclic, with generator $v$, say. Write $v_i = v_i^t$, $i = 0, 1, \ldots, n-1$. Then each $v_i$ is a generator of a $C_n$ factor of $V$. The kernel $A_n$ of $\mathcal{N}$ is a cyclic $C_n$-module on the generator $a = v_0 v_1^{-1}$. Write $a_i = a_i^t = v_i v_{i+1}^{-1}$. As an abelian group, $A_n$ has generators $a_0, a_1, \ldots, a_{n-1}$ with relations $a_i^n = 1$, $a_0 a_1 \cdots a_{n-1} = 1$.

We define a morphism $f_* : F_* \to \mathcal{N}$ as follows.

1. $f_1$ maps $w$ to $u$,
2. $f_2$ maps the module generator $w_0$ of $F_2$ to $v = v_0$.
3. $f_3$ maps the module generator $w_0$ of $F_3$ to $a_0$.

The operator morphisms $f_r$ over $f_1$ are defined completely by these conditions.

The group of operator morphisms $g : (C_\infty)^n \to A_n$ over $f_1$ may be identified with $A_n$ under $g \mapsto g(w_0)$. Under this identification, the boundaries $\delta_4, \delta_3$ are transformed respectively to 0 and to $a_i \mapsto a_i(a_i^t)^{-1}$. So the 3-dimensional cohomology group is the group $A_n$ with $a_i$ identified with $a_{i+1}, i = 0, \ldots, n - 1$. This cohomology group is therefore isomorphic to $C_n$, and a generator is the class of the above cocycle $f_3$. 

$\square$
Corollary 5.5 The mapping cone $X = BC_n^2 \cup B_1 \Gamma BC_n$ satisfies $\pi_1 X = C_n$, and $\pi_2 X$ is the $C_n$-module $A_n$ of Theorem 5.4. The first Postnikov invariant of $X$ is a generator of the cohomology group $H^3(\pi_1 X, \pi_2 X)$, which is a cyclic group of order $n$.

The following is another example of a determination of a non trivial cohomology class by a crossed module. The method of proof is similar to that of Theorem 5.4, and is left to the reader.

Example 5.6 Let $n$ be even. Let $C_n'$ denote the $C_n$-module which is $C_n$ as an abelian group but in which the generator $t$ of the group $C_n$ acts on the generator $t'$ of $C_n'$ by sending it to its inverse. For $n = 2$, this gives the trivial module. Then $H^3(C_n, C_n') \cong C_2$ and a generator of this group is represented by the crossed module $\nu_n : C_n \times C_n \to C_n^2$, with generators $t_0, t_1, u$ say, and where $\nu_n t_0 = \nu_n t_1 = u^n$. Here $u \in C_n^2$ operates by switching $t_0, t_1$. However, it is not clear if this crossed module can be an induced crossed module for $n > 2$.
