A Single Time-Scale Stochastic Approximation Method for Nested Stochastic Optimization

Saeed Ghadimi∗, Andrzej Ruszczyński† and Mengdi Wang‡

December 5, 2018

Abstract

We study constrained nested stochastic optimization problems in which the objective function is a composition of two smooth functions whose exact values and derivatives are not available. We propose a single time-scale stochastic approximation algorithm, which we call the Nested Averaged Stochastic Approximation (NASA), to find an approximate stationary point of the problem. The algorithm has two auxiliary averaged sequences (filters) which estimate the gradient of the composite objective function and the inner function value. By using a special Lyapunov function, we show that NASA achieves the sample complexity of $O(1/\epsilon^2)$ for finding an $\epsilon$-approximate stationary point, thus outperforming all extant methods for nested stochastic approximation. Our method and its analysis are the same for both unconstrained and constrained problems, without any need of batch samples for constrained nonconvex stochastic optimization. We also present a simplified variant of the NASA method for solving constrained single level stochastic optimization problems, and we prove the same complexity result for both unconstrained and constrained problems.

1 Introduction

The main objective of this work is to propose a new recursive stochastic algorithm for constrained smooth composition optimization problems of the following form:

$$\min_{x \in X} \{ F(x) = f(g(x)) \}. \quad (1.1)$$

Here, the functions $f : \mathbb{R}^m \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}^m$ are continuously differentiable, and the set $X \subseteq \mathbb{R}^n$ is convex and closed. We do not assume $f$, $g$, or $F$ to be convex.

We focus on the simulation setting where neither the values nor the derivatives of $f$ or $g$ can be observed, but at any argument values $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$ we can obtain random estimates of $g(x)$, of the Jacobian $\nabla g(x)$, and of the gradient $\nabla f(u)$. Such situations occur in stochastic composition optimization, where we need to solve the problem:

$$\min_{x \in X} \mathbb{E}[\varphi(\mathbb{E}[\psi(x; \xi)]; \xi)], \quad (1.2)$$

in which $\xi$ and $\zeta$ are random vectors, and $\mathbb{E}$ denotes the expected value. In such situations, one can obtain samples $(\xi, \xi')$ of $(\xi, \xi)$, and treat $\psi(x, \xi)$, $\nabla_x \psi(x, \xi)$, and $\nabla_u \varphi(u, \xi)$ as random estimates of $\mathbb{E}[\psi(x; \xi)]$, $\nabla \mathbb{E}[\psi(x; \xi)]$, and $\nabla \mathbb{E}[\varphi(u, \xi)]$, respectively. In this paper, we aim to develop stochastic gradient-type methods for finding approximate stationary points of problems of this type. We are also deriving sample complexity guarantees for these methods.

Stochastic composition problems of form (1.1)–(1.2) occur in many applications; we present three modern motivating examples.

Example 1 (Stochastic Variational Inequality) We have a random mapping $H : \mathbb{R}^n \times \Omega \to \mathbb{R}^n$ on some probability space $(\Omega, \mathcal{F}, P)$ and a closed convex set $X$. The problem is to find $x \in X$ such that

$$\langle \mathbb{E}[H(x)], \xi - x \rangle \leq 0, \quad \text{for all} \quad \xi \in X. \quad (1.3)$$

The reader is referred to the recent publications [10] and [12] for a discussion of the challenges associated with this problem and its applications. We propose to convert problem (1.3) to the nested form (1.1) by defining the function $f : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ as

$$f(x, h) = \max_{\xi \in X} \left\{ \langle h, \xi - x \rangle - \frac{1}{2}||\xi - x||^2 \right\},$$

and the function $g : \mathbb{R}^n \to \mathbb{R}^n \times \mathbb{R}^n$ as $g(x) = (x, \mathbb{E}[H(x)])$. In this case, we actually have access to the gradient of $f$, but the value and the Jacobian of $g$ must be estimated. We do not require that $E[H(x)]$ is monotone. □
Example 2 (Policy Evaluation for Markov Decision Processes) For a Markov chain \( \{X_0, X_1, \ldots \} \subset \mathcal{X} \) with unknown transition operator \( P \), a reward function \( r : \mathcal{X} \mapsto \mathbb{R} \), and a discount factor \( \gamma \in (0, 1) \), we want to estimate the value function \( V : \mathcal{X} \mapsto \mathbb{R} \) given by \( V(x) = \mathbb{E} \left[ \sum_{t=0}^{\infty} \gamma^t r(X_t) \mid X_0 = x \right] \). For a finite space \( \mathcal{X} \), the function \( V \) may be viewed as a vector, and the estimation problem can be formulated as a Bellman residual minimization problem, which takes the form of a composition optimization:

\[
\min_{V \in \mathbb{R}^{\mid \mathcal{X} \mid}} \mathbb{E} \left[ (V(X_t) - r(X_t) - \gamma \mathbb{E}[V(X_{t+1}) \mid X_t])^2 \right].
\]

To reduce the dimension of this problem, we can employ a sketching matrix \( S \in \mathbb{R}^{d \times \mid \mathcal{X} \mid} \) and a linear model for the value function \( V(x) \approx \sum_{i=1}^{k} w_i \phi_i(x) \), where \( \phi(\cdot) = [\phi_1(\cdot), \ldots, \phi_k(\cdot)] \) are given basis functions. The Bellman residual minimization problem becomes

\[
\min_{w \in \mathbb{R}^d} \|S (\Phi w - r - \gamma \mathbb{E}[\hat{P} \Phi w])\|^2,
\]

where \( S \) is the sketching matrix, \( \Phi \) is the matrix with columns being the basis functions, and \( \hat{P} \) is a sample transition matrix. In this case, the outer function \( f \) is the squared norm and the inner function \( g \) is the sketched linear mapping. Neither of the functions has an easily available value or derivative, but their samples can be generated by simulation. \( \square \)

Example 3 (Low-Rank Matrix Estimation) Let \( \tilde{X} \in \mathbb{R}^{n \times n} \) be an unknown matrix that we aim to approximate. One can sample from the unknown matrix and each sample returns a random matrix \( X \) such that \( \mathbb{E}[X] = \tilde{X} \). Let \( k < n \) be a pre-specified rank. The low-rank matrix estimation problem has the following form:

\[
\min_{(U, V) \in S} \ell \left( \mathbb{E}[X] - UV^T \right).
\]

In this problem, the unknowns \( U \) and \( V \) are \( n \times k \) matrices, \( S \subset \mathbb{R}^{n \times k} \times \mathbb{R}^{n \times k} \) is a bounded set, and \( \ell : \mathbb{R}^{n \times n} \to \mathbb{R} \) is a loss function (e.g., the Frobenius norm). Low-rank matrix approximation finds wide applications including image analysis, topic models, recommendation systems, and Markov models. It is nonconvex. When data arrive sequentially, our method can be applied in an on-line fashion to find a stationary solution. \( \square \)

Interest in stochastic approximation algorithms for problems of form (1.1) dates back to [5, Ch. V.4], where penalty functions for stochastic constraints and
composite regression models were considered. There, and in the literature that followed, the main approach was to use two- or multiple-level stochastic recursive algorithms in different time scales. For problems of form (1.1) this amounts to using two stepsize sequences: one for updating the main decision variable $x$, and another one for filtering the value of the inner function $g$. The crucial requirement is that the outer method must be infinitely slower than the inner method, which decreases the convergence rate and creates practical difficulties. Sample complexity analysis and acceleration techniques of stochastic approximation methods with multiple time scales for solving problems of form (1.1) gained interests in recent years. We refer the readers to [20, 21, 23] for a detailed account of these techniques and existing results for the general nested composition optimization problem. Furthermore, a Central Limit Theorem for the stochastic composition problem (1.1)-(1.2) has been established in [4]. It shows that the $n$-sample empirical optimal value of problem (1.2) converges to the true optimal value at a rate of $O(1/\sqrt{n})$.

In addition to the general solution methods studied in [4, 20, 21, 23], several notable special cases of the composition problem have been considered in the machine learning literature. In the case where $f$ is convex and $g$ is linear, one can solve (1.1) using duality-based methods via a Fenchel dual reformulation [2]. In the case where it is allowed to take mini-batches, Ref. [1] proposed a sampling scheme to obtain unbiased sample gradients of $F$ by forming randomly sized mini-batches. In the case when $f$ and $g$ take the form of a finite sum and strong convexity holds, one can leverage the special structure to obtain linearly convergent algorithms; see e.g. [13, 14]. To the authors’ best knowledge, no method exists for solving (1.1) with general smooth $f$ and $g$, which uses a single time-scale stochastic approximation update and does not resort to mini-batches. There is also no method for approximating stationary solutions that has provable complexity bounds, when the composition problem is constrained.

Our contributions are the following. First, we propose a new Nested Averaged Stochastic Approximation (NASA) algorithm for solving (1.1), which is qualitatively different from the earlier approaches. Its main idea, inspired by [18, 16], is to lift the problem into a higher dimensional space, $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m$, where our objective is not only to find the optimal $x$, but also to find the gradient of $F$ at the optimal point, and the value of $g$ at this point. In this space, we construct an iterative method using one stepsize sequence, and we prove convergence by employing a specially tailored merit (Lyapunov) function. This leads to the first single-timescale stochastic approximation algorithm for the composition problem, and entails essential improvements over the earlier approaches.

Secondly, we show that with proper choice of the stepsize sequence, $O(1/\varepsilon^2)$ observations are sufficient for NASA algorithm to find a pair $(\bar{x}, \bar{z}) \in X \times \mathbb{R}^n$ satisfying $\mathbb{E}[V(\bar{x}, \bar{z})] \leq \varepsilon$, where $\bar{z}$ is an estimate for $\nabla F(\bar{x})$, and $V(x, z)$ is an optimality
measure generalizing $\|\nabla F(\bar{x})\|^2$ to constrained problems; see (2.9). This complexity bound is consistent with the Central Limit Theorem for composite risk functionals [4] and is better than the best-known complexity of $O(1/\varepsilon^{2.25})$ obtained in [21] for smooth nested nonconvex stochastic optimization. In fact, our complexity bound for the two-level composition problem is of the same order as the complexity of the stochastic gradient method for general smooth one-level nonconvex stochastic optimization [6].

Thirdly, our convergence analysis of the NASA method is the same for both unconstrained and constrained problems, allowing us to obtain the same complexity of $O(1/\varepsilon^2)$ for the constrained case, without taking batches of samples per iterations. To the best of our knowledge, this is the first direct convergence analysis for constrained nonconvex stochastic optimization avoiding multiple samples per iteration to reduce the variance of the stochastic gradients. Hence, this property makes the NASA method attractive for online learning where the samples are received one by one.

Finally, we present a simplified variant of the NASA method for solving a class of single-level stochastic optimization problem, i.e., with $g(x) \equiv x$ in problem (1.1). This simplified version is a form of a constrained dual averaging method. We show that the sample (iteration) complexity of this algorithm is of the same order as that of the NASA method. Moreover, the stepsize schedule of this method, unlike almost all existing stochastic approximation algorithms, does not depend on any problem parameters or employ line-search procedures. Its rate of convergence is established without forming mini-batches of samples, and is valid for both unconstrained and constrained problems. It should be mentioned that a similar complexity bound has recently been obtained in [3] for finding an approximate stationary point (albeit with a different optimality measure) for nonsmooth, constrained, and nonconvex one-level stochastic optimization problems without taking mini-batch of samples per iteration.

**Notation.** The optimal value of problem (1.1) is denoted by $F^*$. For any Lipschitz continuous function $h$, we use $L_h$ to denote its Lipschitz constant. We use $\nabla h$ to denote the gradient (or Jacobian) of a scalar (or vector) function $h$.

## 2 The Method

Our goal in this section is to propose a stochastic approximation algorithm for solving problem (1.1) where estimates of the gradient of $f$ and the value and Jacobian of $g$ are available through calls to a stochastic oracle.

The method generates three random sequences, namely, approximate solutions $\{x^k\}$, average gradients $\{z^k\}$, and average $g$-values $\{u^k\}$, defined on a cer-
tain probability space \((\Omega, \mathcal{F}, P)\). We let \(\mathcal{F}_k\) to be the \(\sigma\)-algebra generated by \(\{x^0, \ldots, x^k, z^0, \ldots, z^k, u^0, \ldots, u^k\}\). We also make the following assumption on the stochastic oracle.

**Assumption 1** For each \(k\), the stochastic oracle delivers random vectors \(G^{k+1} \in \mathbb{R}^m, s^{k+1} \in \mathbb{R}^n\), and a random matrix \(J^{k+1} \in \mathbb{R}^{m \times n}\), such that

\[
\begin{align*}
\mathbb{E}[G^{k+1} | \mathcal{F}_k] &= g(x^{k+1}), \\
\mathbb{E}[\|G^{k+1} - g(x^{k+1})\|^2 | \mathcal{F}_k] &\leq \sigma_G^2, \\
\mathbb{E}[J^{k+1} | \mathcal{F}_k] &= \nabla g(x^{k+1}), \\
\mathbb{E}[\|J^{k+1}\|^2 | \mathcal{F}_k] &\leq \sigma_J^2, \\
\mathbb{E}[s^{k+1} | \mathcal{F}_k] &= \nabla f(u^k), \\
\mathbb{E}[\|s^{k+1}\|^2 | \mathcal{F}_k] &\leq \sigma_s^2.
\end{align*}
\]

The shift in indexing of \(x^k\) in the above assumption is due to the fact that \(x^{k+1}\) will be \(\mathcal{F}_k\)-measurable in our method. Our method proceeds as follows.

**Algorithm 1** Nested Averaged Stochastic Approximation (NASA)

**Input:** \(x^0 \in X, z^0 \in \mathbb{R}^n, u^0 \in \mathbb{R}^m\), positive constants \(a, b\), positive sequences \(\{\beta_k\}_{k \geq 0}\) and \(\{\tau_k\}_{k \geq 0} \subset (0, 1/a]\).

0. Set \(k = 0\).

1. Compute

\[
y^k = \arg\min_{y \in X} \left\{ \langle z^k, y - x^k \rangle + \frac{\beta_k}{2} \|y - x^k\|^2 \right\},
\]

and set

\[
x^{k+1} = x^k + \tau_k (y^k - x^k).
\]

2. Call the stochastic oracle to obtain \(s^{k+1}\) at \(u^k\), \(G^{k+1}\) at \(x^{k+1}\), and \(J^{k+1}\) at \(x^{k+1}\), and update the running averages as

\[
\begin{align*}
z^{k+1} &= (1 - a \tau_k) z^k + a \tau_k \langle J^{k+1} \rangle^T s^{k+1}, \\
u^{k+1} &= (1 - b \tau_k) u^k + b \tau_k G^{k+1}.
\end{align*}
\]

3. Increase \(k\) by one and go to Step 1.

A few remarks are in order. First, the stochastic gradient \(\langle J^{k+1} \rangle^T s^{k+1}\) returned by the stochastic oracle is a biased estimator of the gradient of \(F(x^{k+1})\). Hence, \(z^{k+1}\), as a weighted average of these stochastic gradients, is also a biased estimator of \(\nabla F(x^{k+1})\). However, the sum of the bias terms of the latter estimator grows slower than the former one, ensuring convergence of the algorithm (see Theorem 2). Secondly, \(u^{k+1}\) is also a biased estimator of \(g(x^{k+1})\), whose error can be
properly controlled and asymptotically driven to 0. Finally, convergence of Algorithm 1 depends on the choice of the sequences \( \{ \tau_k \} \) and \( \{ \beta_k \} \) and the parameters \( a \) and \( b \), which will be specified in the next section. The stepsize sequences \( \{ \tau_k \} \) and \( \{ \beta_k \} \) will be chosen to reduce to zero on the same timescale.

We end this section with a brief review of the optimality conditions for problem (1.1) and their relation to the subproblem (2.4). The following result is standard (see, e.g., [17, Thm. 3.24].

**Theorem 1** If a point \( \hat{x} \in X \) is a local minimum of problem (1.1), then

\[
-\nabla F(\hat{x}) \in \mathcal{N}_X(\hat{x}),
\]

where \( \mathcal{N}_X(\hat{x}) \) denotes the normal cone to \( X \) at the point \( \hat{x} \). If in addition the function \( F(\cdot) \) is convex, then every point \( \hat{x} \) satisfying (2.8) is the global minimum of problem (1.1).

Condition (2.8) is closely related to the subproblem (2.4). Denote (for \( \beta > 0 \))

\[
\bar{y}(x, z, \beta) = \arg \min_{y \in X} \left\{ \langle z, y - x \rangle + \frac{\beta}{2} \| y - x \|^2 \right\}.
\]

Elementary manipulation shows that

\[
\bar{y}(x, z, \beta) = \Pi_X \left( x - \frac{1}{\beta} z \right),
\]

where \( \Pi_X(\cdot) \) is the operation of the orthogonal projection on the set \( X \). The relation \( -z \in \mathcal{N}_X(x) \) is equivalent to \( \bar{y}(x, z, \beta) = x \). We will, therefore, use the function

\[
V(x, z) = \| \bar{y}(x, z, 1) - x \|^2 + \| z - \nabla F(x) \|^2
\]

(2.9)

as a measure of violation of the optimality condition (2.8) by the primal-dual pair \( (x, z) \). In the unconstrained case where \( X = \mathbb{R}^n \), we have \( V(x, z) = \| z \|^2 + \| z - \nabla F(x) \|^2 \).

The following lemma relates the optimality measure \( V(x, z) \) to subproblem (2.4) for an arbitrary \( \beta > 0 \).

**Lemma 1** For every \( x \in X \) and every \( \beta > 0 \),

\[
\| \bar{y}(x, z, 1) - x \| \leq \max(1, \beta) \| \bar{y}(x, z, \beta) - x \|.
\]

(2.10)

**Proof.** To simplify notation, set \( x = 0 \), \( y(\beta) = \bar{y}(x, z, \beta) = \Pi_X \left( -\frac{1}{\beta} z \right) \). By the characterization of the orthogonal projection,

\[
\langle z + \tau y(\tau), \xi - y(\tau) \rangle \geq 0 \quad \text{for all} \quad \xi \in X, \quad \tau > 0.
\]

(2.11)
Setting \( \tau = \beta \) and \( \xi = y(1) \) we obtain
\[
\langle z + \beta y(\beta), y(1) - y(\beta) \rangle \geq 0.
\]
Now we set \( \tau = 1 \) and \( \xi = y(\beta) \) in (2.11) and get
\[
\langle z + y(1), y(\beta) - y(1) \rangle \geq 0.
\]
Adding these inequalities yields
\[
\langle \beta y(\beta) - y(1), y(1) - y(\beta) \rangle \geq 0.
\] (2.12)

Consider two cases.

Case 1: \( \beta \geq 1 \). Inequality (2.12) implies that
\[
(\beta - 1)\|y(\beta)\| = \|\beta y(\beta) - y(\beta)\| \geq \|y(1) - y(\beta)\|.
\]
By the triangle inequality and the last relation,
\[
\|y(1)\| \leq \|y(\beta)\| + \|y(1) - y(\beta)\| \leq \beta \|y(\beta)\|.
\]
which proves our claim in this case.

Case 2: \( 0 < \beta \leq 1 \). From (2.12) we obtain
\[
(1 - \beta)\langle y(\beta) - y(1), y(1) \rangle \geq \beta \|y(\beta) - y(1)\|^2 \geq 0.
\]
Therefore \( \|y(\beta)\| \geq \|y(1)\| \) and our claim is true in this case as well.

3 Convergence Analysis

In this section, we provide convergence analysis of Algorithm 1. To do so, we need the following assumption.

**Assumption 2** The functions \( f \) and \( g \) and their derivatives are Lipschitz continuous.

This immediately implies that the gradient of the composite function \( F \) is Lipschitz continuous.

**Lemma 2** Under Assumption 2 the gradient of the function \( F \) defined in (1.1) is Lipschitz continuous with \( L_F := L_2^2 L_N f + L_f L_N g \).
Proof. Let \(x, \hat{x} \in X\) be given. Then, by the chain rule we have
\[
\|\nabla F(x) - \nabla F(\hat{x})\| = \|\nabla g(x)^\top \nabla f(g(x)) - \nabla g(\hat{x})^\top \nabla f(g(\hat{x}))\|
\leq \|\nabla g(x)\| \|\nabla f(g(x)) - \nabla f(g(\hat{x}))\| + \|\nabla f(g(\hat{x}))\| \|\nabla g(x) - \nabla g(\hat{x})\|
\leq (L_w^2 L_{\nabla f} + L_f L_{\nabla g})\|x - \hat{x}\|.
\]

The next result about the subproblem employed at Step 2 of Algorithm 1 will be used in our convergence analysis.

**Lemma 3** Let \(\eta(x,z)\) be the optimal value of subproblem (2.4) for any \((x,z)\), i.e.,
\[
\eta(x,z) = \min_{y \in X} \left\{ \langle z, y - x \rangle + \frac{\beta}{2} \|y - x\|^2 \right\}.
\]
(3.13)
Then the gradient of \(\eta\) w.r.t. \((x,z)\) is Lipschitz continuous with the constant
\[
L_{\nabla \eta} = 2\sqrt{(1 + \beta)^2 + (1 + \frac{1}{2\beta^2})^2}.
\]

Proof. Let \(\hat{y}(x,z) \in X\) be the solution of (3.13). Since the solution is unique, the partial derivatives of the optimal value function \(\eta\) are given by
\[
\nabla_x \eta(x,z) = -z + \beta(x - \hat{y}(x,z)), \quad \nabla_z \eta(x,z) = \hat{y}(x,z) - x.
\]
Hence, for any \((x,z)\) and \((\hat{x}, \hat{z})\), we have
\[
\|\nabla \eta(x,z) - \nabla \eta(\hat{x}, \hat{z})\| \leq \|\nabla_x \eta(x,z) - \nabla_x \eta(\hat{x}, \hat{z})\| + \|\nabla_z \eta(x,z) - \nabla_z \eta(\hat{x}, \hat{z})\|
\leq 2(1 + \beta)\|x - \hat{x}\| + (2 + 1/\beta)\|z - \hat{z}\| \leq L_{\nabla \eta}\|\eta(x,z) - (x,z)\|,
\]
where the inequalities follow from the nonexpansiveness of the projection operator and the Cauchy-Schwarz inequality, respectively.

The proof of convergence of Algorithm 1 follows from the analysis of the following merit function:
\[
W(x,z,u) = a(F(x) - F^*) - \eta(x,z) + \frac{\gamma}{2}\|g(x) - u\|^2,
\]
(3.14)
where \(\gamma > 0\) and \(\eta(x,z)\) is the optimal value of subproblem (3.13).

**Lemma 4** Let \(\{x^k, z^k, y^k, u^k\}_{k \geq 0}\) be the sequence generated by Algorithm 1. Also assume that Assumption 2 holds, and
\[
\beta_k = \beta > 0 \quad \forall k \geq 0, \quad 2(a \beta - c)(\gamma b - 2c) \geq L_w^2 (a L_{\nabla f} + \gamma)^2
\]
(3.15)
for some positive constants \( c \) and \( \gamma \). Then
\[
c \sum_{k=0}^{N-1} \tau_k \left( \|d^k\|^2 + \|g(x^k) - u^k\|^2 \right) \leq W(x^0, z^0, u^0) + \sum_{k=0}^{N-1} r^{k+1} \quad \forall N \geq 1, \quad (3.16)
\]
where, for any \( k \geq 0 \),
\[
d^k = y^k - x^k,
\]
\[
r^{k+1} = \frac{\tau_k^2}{2} \left( [aLFX + L\nu \gamma + 2aL^2 + 2aL^2 L\nu] \|d^k\|^2 + b^2 \|g(x^{k+1}) - G^{k+1}\|^2 \right)
+ \tau_k \left( \gamma b (1 + b \tau_k) \langle g(x^{k+1}) - a, \Delta_k^g \rangle + a(d^k, \Delta_k^F) \right) + \frac{L\nu \gamma}{2} \|z^{k+1} - z^k\|^2,
\]
\[
\Delta_k^g = g(x^{k+1}) - G^{k+1}, \quad \Delta_k^F := \nabla g(x^{k+1})^\top f(u^k) - [f^{k+1}]^\top s^{k+1}. \quad (3.17)
\]

**Proof:** We estimate the decrease of the three terms of the function \( W(x, z, u) \) in iteration \( k \).

1. Due to Assumption 2 and in view of Lemma 2, we have
\[
F(x^k) - F(x^{k+1}) \geq \langle \nabla F(x^{k+1}), x^k - x^{k+1} \rangle - \frac{L\nu}{2} \|x^k - x^{k+1}\|^2.
\]

After re-arranging the terms and using (2.5), we obtain
\[
F(x^{k+1}) - F(x^k) \leq \tau_k \langle \nabla F(x^{k+1}), d^k \rangle + \frac{L\nu \gamma}{2} \|d^k\|^2. \quad (3.18)
\]

2. By (2.5), (2.6), and Lemma 3, we have
\[
\eta(x^k, z^k) - \eta(x^{k+1}, z^{k+1}) \leq \langle z^k + \beta_k(y^k - x^k), x^{k+1} - x^k \rangle - \langle y^k - x^k, z^{k+1} - z^k \rangle
+ \tau_k \left( \gamma b (1 + a) z^k + \beta_k d^k, d^k \right) - a \tau_k \langle d^k, [f^{k+1}]^\top s^{k+1} \rangle
+ \frac{L\nu \gamma}{2} \left[ \|x^{k+1} - x^k\|^2 + \|z^{k+1} - z^k\|^2 \right]. \quad (3.19)
\]

Due to the optimality condition of subproblem (2.4), we have \( \langle z^k + \beta_k(y^k - x^k), y - y^k \rangle \geq 0 \), for all \( y \in X \), which together with the choice of \( y = x^k \) implies that
\[
\langle z^k, d^k \rangle + \beta_k \|d^k\|^2 \leq 0. \quad (3.20)
\]

Combining the last relation with (3.19), we obtain
\[
\eta(x^k, z^k) - \eta(x^{k+1}, z^{k+1}) \leq -a \tau_k \langle d^k, \nabla g(x^{k+1})^\top f(u^k) \rangle
+ a \tau_k \langle d^k, \nabla g(x^{k+1})^\top f(u^k) - [f^{k+1}]^\top s^{k+1} \rangle
+ \frac{L\nu \gamma}{2} \left[ \|x^{k+1} - x^k\|^2 + \|z^{k+1} - z^k\|^2 \right]. \quad (3.21)
\]
3. By (2.7), we have
\[
\|g(x^{k+1}) - u^k\|^2 = (b\tau_k)^2\|g(x^{k+1}) - G^{k+1}\|^2 + (1 - b\tau_k)^2\|g(x^{k+1}) - u^k\|^2 + 2b\tau_k(1 - b\tau_k)\langle g(x^{k+1}) - G^{k+1}, g(x^{k+1}) - u^k\rangle,
\]
where the last inequality follows from (2.5) and the Lipschitz continuity of $g$. Moreover, using (2.5) and Assumption 2, we obtain
\[
\|g(x^{k+1}) - u^k\|^2 \leq \|g(x^k) - u^k\|^2 + L_g^2\tau_k^2\|d^k\|^2 + 2L_g\tau_k\|d^k\||g(x^k) - d^k|, \tag{3.22}
\]
where $\tau_k$ is defined in (3.17). Hence, when condition (3.15) holds, we have
\[
\langle d^k, \nabla F(x^{k+1}) - \nabla g(x^{k+1})\rangle \leq L_gL_{\nabla f}\left[\tau_kL_g\|d^k\|^2 + \|d^k\||g(x^k) - u^k\|\right]. \tag{3.23}
\]

4. The overall estimate is obtained by combining the (3.14), (3.18), (3.21), (3.22), and (3.23):
\[
W(x^{k+1}, z^{k+1}, u^{k+1}) - W(x^k, z^k, u^k) \leq -\gamma_k \left(a\beta_k\|d^k\|^2 + \frac{\gamma b}{2}\|g(x^k) - u^k\|^2 - (aL_gL_{\nabla f} + \gamma L_g)\|d^k\||g(x^k) - u^k\|\right) + \rho^{k+1},
\]
where $\rho^{k+1}$ is defined in (3.17). Hence, when condition (3.15) holds, we have
\[
W(x^{k+1}, z^{k+1}, u^{k+1}) - W(x^k, z^k, u^k) \leq -c\tau_k \left(\|d^k\|^2 + \|g(x^k) - u^k\|^2\right) + \rho^{k+1}.
\]
Observe that $\eta(x, z) \leq 0$ for any $(x, z)$, due to (3.20). Therefore, $W(x, z, u) \geq 0$ for all $(x, z, u)$. Summing up both sides of the above inequalities, re-arranging the terms, we obtain (3.16).

As a consequence of the above result, we can provide upper bounds for the sequences generated by Algorithm 1.

**Proposition 1** Let $\{x^k, z^k, u^k\}_{k \geq 0}$ be the sequence generated by Algorithm 1 and Assumption 2 hold. Then:
(a) If $\tau_0 = 1/a$, we have
\[
\beta_k^2\mathbb{E}\left[\|d^k\|^2 | \mathcal{F}_{k-1}\right] \leq \mathbb{E}\left[\|z^k\|^2 | \mathcal{F}_{k-1}\right] \leq \sigma_f^2 \sigma_z^2 \quad \forall k \geq 1;
\]
(b) If Assumption 2 also holds, then we have
\[
\sum_{k=0}^{\infty} \mathbb{E}[\|z^{k+1} - z^k\|^2 | \mathcal{F}_k] \leq 4\sigma_f^2 \sigma_z^2 \sum_{k=0}^{\infty} \tau_k^2,
\]
\[
\sum_{k=0}^{\infty} \mathbb{E}[r^{k+1} | \mathcal{F}_k] \leq \sigma^2 \sum_{k=0}^{\infty} \tau_k^2.
\]
where
\[
\sigma^2 = \frac{1}{2} \left( L_{VF} + L_{VH} + \gamma L^2_k + 2aL^2_k L_{VF} \frac{\sigma^2 \sigma^2}{\beta^2} + b^2 \sigma^2 + 4L_{VH} \sigma^2 \sigma^2 \right). \tag{3.24}
\]

Proof. We first show part (a). The first inequality follows immediately from (3.20) and the Cauchy-Schwarz inequality. Also, defining
\[
\Gamma_1 := \begin{cases} 1, & \tau_0 = 1/a, \\ 1 - a \tau_0, & \tau_0 < 1/a, \end{cases} \quad \Gamma_k := \Gamma_1 \prod_{i=1}^{k-1} (1 - a \tau_i) \quad \forall k \geq 2, \tag{3.25}
\]
and noting (2.6), we obtain
\[
\frac{z^1}{\Gamma_1} = \frac{(1 - a \tau_0) z^0}{\Gamma_1} + \frac{a \tau_0}{\Gamma_1} [J^1] s^1, \quad \frac{z^{k+1}}{\Gamma_{k+1}} = \frac{z^k}{\Gamma_k} + \frac{a \tau_k}{\Gamma_{k+1}} [J^{k+1}] s^{k+1} \quad \forall k \geq 1.
\]
Summing up the above inequalities and assuming that \( \tau_0 = 1/a \), we obtain, for any \( k \geq 1 \),
\[
z^k = \sum_{i=0}^{k-1} \alpha_{i,k} [J^{i+1}]^	op s^{i+1}, \quad \alpha_{i,k} = \frac{a \tau_i}{\Gamma_{i+1}}, \quad \sum_{i=0}^{k-1} \alpha_{i,k} = 1, \tag{3.26}
\]
where the last equality follows from the fact that
\[
\sum_{i=0}^{k-1} \frac{a \tau_i}{\Gamma_{i+1}} = \frac{a \tau_0}{\Gamma_1} + \sum_{i=1}^{k-1} \frac{a \tau_i}{(1 - a \tau_i) \Gamma_i} = \frac{a \tau_0}{\Gamma_1} + \sum_{i=1}^{k-1} \left( \frac{1}{\Gamma_{i+1}} - \frac{1}{\Gamma_i} \right) = \frac{1}{\Gamma_k} - \frac{1 - a \tau_0}{\Gamma_1}.
\]
Therefore, noting that \( \| \cdot \|_2 \) is a convex function and using Assumption [1] we conclude that
\[
\mathbb{E} \left[ \| z^k \|^2 \mid \mathcal{F}_{k-1} \right] \leq \sum_{i=0}^{k-1} \alpha_{i,k} \mathbb{E} \left[ \| J^{i+1} \|^2 \mid \mathcal{F}_i \right] \mathbb{E} \left[ \| s^{i+1} \|^2 \mid \mathcal{F}_i \right] \leq \sigma^2 \sigma^2 \sum_{i=0}^{k-1} \alpha_{i,k} = \sigma^2 \sigma^2.
\]
We now show part (b). By (2.6), we have
\[
\mathbb{E} \left[ \| z^{k+1} - z^k \|^2 \mid \mathcal{F}_k \right] \leq 2 \tau_k^2 \left( \mathbb{E} \left[ \| z^k \|^2 \mid \mathcal{F}_{k-1} \right] + \mathbb{E} \left[ \| [J^{k+1}]^	op s^{k+1} \|^2 \mid \mathcal{F}_k \right] \right) \leq 4 \sigma^2 \sigma^2 \tau_k^2,
\]
which implies the first inequality in (b). Finally, due to the equation
\[
\mathbb{E} \left[ \langle g(x^{k+1}) - u^k, \Delta_k^m \rangle \mid \mathcal{F}_k \right] = \mathbb{E} \left[ \langle d^k, \Delta_k^m \rangle \mid \mathcal{F}_k \right] = 0,
\]
the second inequality in (b) follows from the first one in (a) and (3.17).

We are now ready to estimate the quality of the iterates generated by Algorithm [1]. In view of Lemma [1] we can bound the optimality measure at iteration \( k \) as follows:
\[
V(x^k, z^k) \leq \max(1, \beta_k^2) \| d^k \|^2 + \| z^k - \nabla F(x^k) \|^2. \tag{3.27}
\]
Theorem 2 Suppose Assumptions [1] and [2] are satisfied and let \( \{x^k, z^k, y^k, u^k\}_{k \geq 0} \) be the sequence generated by Algorithm [1]. Moreover, assume that the stepsizes \( \{\tau_k\} \) are chosen such that (3.15) holds and
\[
\sum_{i=k+1}^{N} \tau_i \Gamma_i \leq \bar{c} \Gamma_{k+1} \quad \forall k \geq 0 \text{ and } \forall N \geq 1,
\]
where \( \Gamma_k \) is defined in (3.25), and \( \bar{c} \) is a positive constant. Then:

(a) For every \( N \geq 1 \), we have
\[
\sum_{k=1}^{N} \tau_k \mathbb{E}[\|\nabla F(x^k) - z^k\|^2 | \mathcal{F}_{k-1}] \leq a \bar{c} \left( \frac{1}{c} \max(L_1, L_2) \sigma^2 + 2a \sigma_f^2 \sigma_*^2 \right) \left( \sum_{k=0}^{N-1} \tau_k^2 \right) + a \bar{c} \max(L_1, L_2) W(x^0, z^0, u^0),
\]
where
\[
L_1 := \frac{2L_2^2}{a^2} + 4L_4^2 \nu_f^2, \quad L_2 := 4L_8^2 \nu_f^2.
\]

(b) As a consequence, we have
\[
\mathbb{E}[V(x^R, z^R)] \leq \frac{1}{\sum_{k=0}^{N-1} \tau_k} \left\{ a \bar{c} \left( \frac{1}{c} \left[ \max(L_1, L_2) + \max(1, \beta^2) \right] \sigma^2 + 2a \sigma_f^2 \sigma_*^2 \right) \left( \sum_{k=0}^{N-1} \tau_k^2 \right) \right. \left. + \frac{1}{c} \left( a \bar{c} \max(L_1, L_2) + \max(1, \beta^2) \right) W(x^0, z^0, u^0) + \|\nabla F(x^0) - z^0\|^2 \right\},
\]
where the expectation is taken with respect to a random integer number \( R \in \{0, \ldots, N-1\} \), independent of the sequences generated by the method, whose probability distribution is given by
\[
P(R = k) = \frac{\tau_k}{\sum_{k=0}^{N-1} \tau_k}.
\]

(c) Moreover, if \( a = b = 1 \) in the method, and the stepsizes are constant and equal to:
\[
\beta_k \equiv \beta = \left( \frac{(1 + \alpha)^2}{\alpha} L_g^2 + \frac{\alpha}{4} \right) L_{\nu_f} \quad \forall k \geq 0,
\]
for any \( \alpha > 0 \), and
\[
\tau_0 = 1, \quad \tau_k \equiv \frac{1}{\sqrt{N}} \quad \forall k = 1, \ldots, N-1,
\]

\(13\)
then
\[
\mathbb{E} \left[ V(x^k, z^k) \right] \leq \frac{4}{\sqrt{N}} \left( \frac{2}{\alpha L_{\nabla F}} \left[ \max(L_1, L_2) + \max(1, \beta^2) \right] \left[ W(x^0, z^0, u^0) + \sigma^2 \right] + \sigma^2 \alpha^2 + \| \nabla F(x^0) - z^0 \|^2 \right),
\]
\[
(3.35)
\]
and
\[
\mathbb{E} \left[ \| g(x^k) - u^k \|^2 \right] \leq \frac{W(x^0, z^0, u^0) + \sigma^2}{\alpha L_{\nabla F} \sqrt{N}}.
\]
\[
(3.36)
\]
\textbf{Proof.} We first show part (a). By (2.6), we have
\[
\nabla F(x^{k+1}) - z^{k+1} = (1 - a \tau_k) [\nabla F(x^k) - z^k + \nabla F(x^{k+1}) - \nabla F(x^k)] + a \tau_k [\nabla F(x^{k+1}) - [J^{k+1}]^\top s^{k+1}].
\]
Dividing both sides of the above inequality by $\Gamma_k$, summing up, noting the fact that $\tau_0 = 1/a$, similar to (3.26), we obtain
\[
\nabla F(x^k) - z^k = \sum_{i=0}^{k-1} \alpha_{i,k} [e_i + \Delta^F_k] \quad \forall k \geq 1,
\]
with
\[
e_i := \frac{(1 - a \tau_k)}{a \tau_k} \left[ \nabla F(x^{k+1}) - \nabla F(x^k) \right] + \nabla F(x^{k+1}) - \nabla g(x^{k+1})^\top \nabla f(u^i),
\]
(3.37)
where $\Delta^F_k$ is defined in (3.17). Hence,
\[
\nabla F(x^{k-1}) - z^{k-1} = \sum_{i=0}^{k-2} \alpha_{i,k-1} [e_i + \Delta^F_k] = \frac{\Gamma_{k-1}}{\Gamma_k} \sum_{i=0}^{k-2} \alpha_{i,k} [e_i + \Delta^F_k],
\]
which together with (3.37) implies that
\[
\| \nabla F(x^k) - z^k \|^2 = \left\| \frac{\Gamma_k}{\Gamma_{k-1}} \left[ \nabla F(x^{k-1}) - z^{k-1} \right] + \alpha_{k-1,k} [e_{k-1} + \Delta^F_{k-1}] \right\|^2
\]
\[
= \left\| (1 - a \tau_{k-1}) \left[ \nabla F(x^{k-1}) - z^{k-1} \right] + a \tau_{k-1} [e_{k-1} + \Delta^F_{k-1}] \right\|^2
\]
\[
= \left\| (1 - a \tau_{k-1}) \left[ \nabla F(x^{k-1}) - z^{k-1} \right] + a \tau_{k-1} e_{k-1} \right\|^2 + a^2 \tau_{k-1} \| \Delta^F_{k-1} \|^2
\]
\[
+ 2a \tau_{k-1} \langle (1 - a \tau_{k-1}) \left[ \nabla F(x^{k-1}) - z^{k-1} \right] + a \tau_{k-1} e_{k-1}, \Delta^F_{k-1} \rangle
\]
\[
\leq (1 - a \tau_{k-1}) \| \nabla F(x^{k-1}) - z^{k-1} \|^2 + a \tau_{k-1} \| e_{k-1} \|^2 + a^2 \tau_{k-1} \| \Delta^F_{k-1} \|^2
\]
\[
+ 2a \tau_{k-1} \langle (1 - a \tau_{k-1}) [\nabla F(x^{k-1}) - z^{k-1} + a \tau_{k-1} e_{k-1}, \Delta^F_{k-1} \rangle,
\]
\[
(3.38)
\]
where the inequality follows from the convexity of $\| \cdot \|^2$. Dividing both sides of the above inequality by $\Gamma_k$, summing them up, noting the facts that $\tau_0 = 1/a$, and $\tau_k \leq 1/a$, we obtain

$$
\| \nabla F(x^k) - z^k \|^2 \leq \Gamma_k \left[ \sum_{i=0}^{k-1} \left( \frac{a\tau_i}{\Gamma_{i+1}} \| e_i \|^2 + \frac{a^2\tau_i^2}{\Gamma_{i+1}} \| \Delta F_i \|^2 + \frac{2a\tau_i \delta_i}{\Gamma_{i+1}} \right) \right],
$$

(3.38)

where

$$
\delta_i := \langle (1-a\tau_i)[\nabla F(x^i) - z^i] + a\tau_i e_i, \Delta F_i \rangle.
$$

Now, using (2.5), (3.23), with a view to Lemma 2, we obtain

$$
\| e_i \|^2 \leq \frac{2L^2_F(1-a\tau_i)^2}{a^2} \| d^i \|^2 + 4L^2_F L^2_f \left[ \tau_i^2 \| \Delta F_i \|^2 + \| g(x^i) - u^i \|^2 \right],
$$

which together with (3.30) implies that

$$
\sum_{k=1}^{N} \left( \tau_k \Gamma_k \sum_{i=0}^{k-1} \frac{a\tau_i}{\Gamma_{i+1}} \| e_i \|^2 \right) \leq \sum_{k=1}^{N} \left( \tau_k \Gamma_k \sum_{i=k+1}^{N} \frac{a\tau_i}{\Gamma_{i+1}} \left[ L_1 \| d^i \|^2 + L_2 \| g(x^i) - u^i \|^2 \right] \right)
$$

$$
= a \sum_{k=0}^{N-1} \left\{ \frac{\tau_k}{\Gamma_{k+1}} \left[ \sum_{i=k+1}^{N} \tau_i \Gamma_i \right] \left[ L_1 \| d^i \|^2 + L_2 \| g(x^i) - u^i \|^2 \right] \right\},
$$

$$
\leq a\bar{c} \sum_{k=0}^{N-1} \left\{ \tau_k \left[ L_1 \| d^k \|^2 + L_2 \| g(x^k) - u^k \|^2 \right] \right\},
$$

(3.39)

where the last inequality follows from the condition (3.28). Similar, this condition implies that

$$
\sum_{k=1}^{N} \left( \tau_k \Gamma_k \sum_{i=0}^{k-1} \frac{a^2\tau_i^2}{\Gamma_{i+1}} \| \Delta F_i \|^2 \right) = a^2 \sum_{k=0}^{N-1} \frac{\tau_k^2}{\Gamma_{k+1}} \left( \sum_{i=k+1}^{N} \tau_i \Gamma_i \right) \| \Delta F_i \|^2 \leq \bar{c}a^2 \sum_{k=0}^{N-1} \tau_k^2 \| \Delta F_i \|^2.
$$

(3.40)

Moreover, under Assumption 1 we have

$$
\mathbb{E}[\| \Delta F_i \|^2 | \mathcal{F}_k] \leq 2 \mathbb{E}[J^{k+1} \chi^k + s^k | \mathcal{F}_k] \leq 2\sigma^2 \mathbb{E}[\| \delta_i \|^2],
$$

$$
\mathbb{E}[\| \delta_i \|^2 | \mathcal{F}_k] = 0.
$$

Therefore, by taking conditional expectation of both sides of (3.38), noting (3.39), (3.40), the above inequality, and Lemma 4, we obtain (3.29). Part (b) then follows from (3.27) and the fact that

$$
\mathbb{E}[V(x^R, z^R)] = \frac{\sum_{k=0}^{N-1} \tau_k \mathbb{E}[V(x^k, z^k)]}{\sum_{k=0}^{N-1} \tau_k},
$$

15
due to (3.32).

To show part (c), observe that condition (3.15) is satisfied by (3.33) and the choice of $\gamma = 4\epsilon = \alpha L_{\nabla f}$. Also by (3.25) and (3.34), we have

$$\sum_{k=0}^{N-1} \tau_k \geq \sqrt{N}, \quad \sum_{k=0}^{N-1} \tau_k^2 \leq 2, \quad \Gamma_k = \left(1 - \frac{1}{\sqrt{N}}\right)^{k-1},$$

$$\sum_{i=k+1}^{N} \tau_i \Gamma_i = \left(1 - \frac{1}{\sqrt{N}}\right)^{k+1} \frac{1}{\sqrt{N}} \sum_{i=0}^{N-k-1} \left(1 - \frac{1}{\sqrt{N}}\right)^i \leq \left(1 - \frac{1}{\sqrt{N}}\right)^k,$$

which ensures (3.28) with $\bar{c} = 1$ and hence, together with (3.31) implies (3.35).

We now add a few remarks about the above result. First, the estimate (3.35) implies that to find an approximate stationary point $(\bar{x}, \bar{z})$ of problem (1.1) satisfying $E[V(\bar{x}, \bar{z})] \leq \epsilon$, Algorithm 1 requires at most $O(1/\epsilon^2)$ iterations (stochastic gradients), which is better than $O(1/\epsilon^{2.25})$ obtained in [21] for unconstrained nonconvex stochastic optimization. Our complexity bound indeed matches the sample complexity of the stochastic gradient method for the general (single-level) smooth nonconvex optimization problem [6]. It is also consistent with the Central Limit Theorem for composite risk functionals [4], because the objective value gap is essentially proportional to the squared gradient norm at an approximate stationary point (in the unconstrained case). Secondly, Theorem 2 provides the same convergence rate of Algorithm 1 for both constrained and unconstrained problems: we can still get sample complexity of $O(1/\epsilon^2)$ with taking only one sample per iteration in the constrained case. To the best of our knowledge, this is the first direct convergence analysis for constrained nonconvex stochastic optimization providing the aforementioned sample complexity. Finally, (3.36) provides not only accuracy bounds for the approximate stationary point $x^*$ but also squared error bounds for estimating the exact value of the inner function, $g(x^*)$, by the second running average, $u^*$. As a result, Algorithm 1 provides not only accurate approximations to the stationary solution but also reliable estimates of the gradients.

For a stochastic variational inequality problem of Example 1, our method has significantly lower complexity and faster convergence than the approach of [10].

We also have the following asymptotic convergence result.

**Theorem 3** Assume that the sequence of stepsizes satisfy

$$\sum_{k=1}^{\infty} \tau_k = +\infty, \quad \sum_{k=1}^{\infty} \tau_k^2 < \infty. \quad (3.41)$$

Then a constant $\bar{a} > 0$ exists such that, for all $a \in (0, \bar{a})$, with probability 1, every accumulation point $(x^*, z^*, u^*)$ of the sequence $\{x^k, z^k, u^k\}$ generated by Algorithm
satisfies the conditions:

\[ z^* = \left[ \nabla g(x^*) \right]^T \nabla f(x^*), \]
\[ u^* = g(x^*), \]
\[ -z^* \in \mathcal{N}_X(x^*). \]

**Proof.** Note that the sequence \( \{r^k\} \) defined in (3.17) is adapted to \( \{\mathcal{F}_k\} \) and summable almost surely under Assumption 1 and (3.41). Therefore, (3.16) implies that

\[ \lim_{k \to \infty} \inf \|d^k\| = 0, \quad \lim_{k \to \infty} \inf \|g(x^k) - u^k\| = 0. \]

Using standard techniques for the stochastic sequences, we can then show that with probability 1, \( d^k \to 0 \) and \( g(x^k) - u^k \to 0 \). Following similar analysis to [16], we derive the convergence of the entire sequence to a stationary point of problem (1.1) and its corresponding gradient.

**4 Dual averaging with constraints**

Although our main interest is in composite optimization, we also provide a simplified variant of Algorithm 1 for solving a single-level stochastic optimization. Our techniques allow the same convergence analysis for both constrained and unconstrained problems which removes the necessity of forming mini-batches of samples per iteration for constrained problems (see e.g., [8, 7]). Moreover, this variant of the NASA method, different from the existing SA-type methods, is a parameter-free algorithm in the sense that its stepsize policy does not depend on any problem parameters. This algorithmic feature is more important under the stochastic setting since estimating problem parameters becomes more difficult.

Throughout this section, we assume that the inner function \( g \) in (1.1) is the identity map, i.e., \( g(x) \equiv x \), and only noisy information about \( f \) is available. In this case, our problem of interest is reduced to

\[ \min_{x \in X} f(x), \quad (4.42) \]

and it is easy to verify that

\[ G = g, \quad J = I, \quad \sigma_G = 0, \quad \sigma_f = 1, \quad L_g = 1, \quad L_{\nabla g} = 0. \quad (4.43) \]

Moreover, Algorithm 1 can be simplified as follows.
Algorithm 2 The Averaged Stochastic Approximation (ASA) Method

Replace Step 2 of Algorithm 1 with the following:

2'. Call the stochastic oracle to obtain $s^{k+1}$ at $x^k$ and update the “running average” as

$$z^{k+1} = (1 - a \tau_k)z^k + a \tau_k s^{k+1}.$$  (4.44)

The above algorithm differs from Algorithm 1 in two aspects. First, stochastic approximation of $\nabla g$ is replaced by its exact value, the identity matrix. Secondly, the averaged sequence in (2.7) is not required and $u^k$ is simply set to $x^k$ due to the fact that exact function values of $g$ are available.

The resulting method belongs to the class of algorithms with direction averaging (multi-step) methods. The literature on these methods for unconstrained problems is very rich. They were initiated in [19], developed and analyzed in [9, 11, 15] and other works. Recently, these methods play a role in machine learning, under the name of dual averaging methods (see [22] and the references therein).

In all these versions, two time-scales were essential for convergence. The first single time-scale method was proposed in [18], with convergence analysis based on a different Lyapunov function suitable for unconstrained problems. Our version is related to [16], where a similar approach was proposed, albeit without rate of convergence estimates.

Convergence analysis of Algorithm 2 follows directly from that of Algorithm 1 by simplifying definition of the merit function as

$$W(x, z) = a(f(x) - f^*) - \eta(x, z),$$  (4.45)

exactly as used in [16]. We then have the following result.

**Lemma 5** Let \(\{x^k, z^k, y^k\}_{k \geq 0}\) be the sequence generated by Algorithm 2. Also assume that function $f$ has Lipschitz continuous gradient and $\beta_k = \beta > 0 \ \forall k \geq 0$. Then:

(a) For any $N \geq 1$, we have

$$\beta \sum_{k=0}^{N-1} \tau_k \|d^k\|^2 \leq W(x^0, z^0) + \sum_{k=0}^{N-1} r^{k+1},$$  (4.46)

where, for any $k \geq 0$,

$$d^k = y^k - x^k, \quad \Delta^f_k = \nabla f(x^k) - s^{k+1},$$

$$r^{k+1} = \frac{1}{2} (3aL_{\nabla f} + L_{\nabla \eta}) \tau_k^2 \|d^k\|^2 + a \tau_k \langle d^k, \Delta^f_k \rangle + \frac{1}{2} L_{\nabla \eta} \|z^{k+1} - z^k\|^2.$$  (4.47)
If, in addition, Assumption 1 holds along with (4.43) and with the choice of \( \tau_0 = 1/a \), we have
\[
\beta^2 \mathbb{E}[\|d^k\|^2 | \mathcal{F}_{k-1}] \leq \mathbb{E}[\|z^k\|^2 | \mathcal{F}_{k-1}] \leq \sigma^2_k \quad \forall k \geq 1,
\]
\[
\sum_{k=0}^{\infty} \mathbb{E}[\|z^{k+1} - z^k\|^2 | \mathcal{F}_k] \leq 4\sigma^2 \sum_{k=0}^{\infty} \tau^2_k,
\]
\[
\sum_{k=0}^{\infty} \mathbb{E}[\|z^k\|^2 | \mathcal{F}_k] \leq \sigma^2 \left( \frac{3aL_{\nabla f} + L_{\nabla \eta}}{2\beta^2} + 2L_{\nabla \eta} \right) \sum_{k=0}^{\infty} \tau^2_k := \sigma^2 \sum_{k=0}^{\infty} \tau^2_k.
\]

**Proof.** With (4.45) and (4.43), the above results follow directly from the proofs of Lemma 5 and Proposition 1 and hence we skip the details. \( \blacksquare \)

Using the above results, we can provide the main convergence property of Algorithm 2.

**Theorem 4** Let \( \{x^k, z^k, y^k\}_{k \geq 0} \) be the sequence generated by Algorithm 2, \( \beta_k = \beta > 0 \ \forall k \geq 0 \), and \( a = 1 \). Moreover, assume that Assumption 1 holds along with (4.43), and the stepsizes are set to (3.34). Then we have
\[
\mathbb{E}[V(x^R, z^R)] \leq \frac{1}{\sqrt{N}} \left( \frac{1}{\beta} \left( \max(1, \beta^2) + L_{\nabla f}^2 \right) \left[ W(x^0, z^0) + 2\sigma^2 \right] + 4 \left[ \sigma^2 + \|\nabla f(x^0) - z^0\|^2 \right] \right),
\]
where \( V(x, z) \) is defined in (2.9).

**Proof.** Similar to (3.37), we have
\[
\nabla F(x^k) - z^k = \sum_{i=0}^{k-1} \alpha_{i,k} \left[ e_i + \Delta^f_i \right], \quad e_i := \frac{\nabla f(x^{i+1}) - \nabla f(x^i)}{a \tau_i},
\]
which together with the Lipschitz continuity of \( \nabla f \) and (2.5) imply that
\[
\|e_i\|^2 \leq \frac{L_{\nabla f}^2 \|d^i\|^2}{a^2}.
\]

In view of Lemma 5, the rest of the proof is similar to that of Theorem 2. \( \blacksquare \)

It is worth noting that unlike Algorithm 1, the stepsize \( \beta_k \) in Algorithm 2 can be set to any positive constant number to achieve the sample (iteration) complexity of \( O(1/\varepsilon^2) \). Such a result has not been obtained before for a parameter-free algorithm for smooth nonconvex stochastic optimization. Moreover, Algorithm 2 similar to Algorithm 1 outputs a pair of \( (x^R, z^R) \) where \( z^R \) is an accurate estimate of \( \nabla f(x^R) \) without taking any additional samples. This is important for both unconstrained
If, in addition, Assumption 3 holds and stepsizes $r_k \geq 0$ for any $N$ (a) Assumption 3 is stated as follows. This order of this section, we modify the convergence analysis of Algorithm 2 under a relaxed assumption that only variance of the stochastic gradient is bounded. This assumption, which is common in the literature on smooth stochastic optimization, is stated as follows. 

**Assumption 3** For each $k$, the stochastic oracle delivers a random vector $s^{k+1} \in \mathbb{R}^n$ such that

$$
\mathbb{E}[s^{k+1} | \mathcal{F}_k] = \nabla f(x^k), \quad \mathbb{E}[\|s^{k+1} - \nabla f(x^k)\|^2 | \mathcal{F}_k] \leq \hat{\sigma}_k^2.
$$

**Lemma 6** Let $\{x^k, z^k, y^k\}_{k \geq 0}$ be the sequence generated by Algorithm 2. Also assume that the function $f$ has a Lipschitz continuous gradient and $\beta_k = \beta > 0$, for all $k \geq 0$. Then:

(a) For any $N \geq 1$, we have

$$
\sum_{k=0}^{N-1} \tau_k \left( \beta_k - \frac{(3aL\eta + L\eta)^2}{2} \right) \|d^k\|^2 \leq W(x^0, z^0) + \sum_{k=0}^{N-1} r^{k+1}, \quad (4.52)
$$

where, for any $k \geq 0$,

$$
r^{k+1} = \langle a \tau_k d^k - a^2 \tau_k^2 L\eta (\nabla F(x^k) - z^k), \Delta_k \rangle + \frac{1}{2} a^2 \tau_k^2 L\eta \left[ \|\nabla F(x^k) - z^k\|^2 + \|\Delta_k\|^2 \right]. \quad (4.53)
$$

(b) If, in addition, Assumption 3 holds and stepsizes $\{\tau_k\}$ are chosen such that

$$
\tau_0 = 1/a, \quad \sum_{i=k+1}^{N} \tau_i^2 \Gamma_i \leq \hat{c} \tau_k \Gamma_{k+1} \quad \forall k \geq 0 \text{ and } \forall N \geq 1, \quad (4.54)
$$

where $\Gamma_k$ is defined in (3.25), and $\hat{c}$ is a positive constant, we have

$$
\sum_{k=0}^{N-1} \tau_k \left( \beta_k - \frac{1}{2} (3aL\eta + L\eta^2) \right) \mathbb{E}[\|d^k\|^2 | \mathcal{F}_k] \leq W(x^0, z^0) + \frac{L\eta}{2} \|\nabla F(x^0) - z^0\|^2 + \frac{1}{2} a^2 (L\eta^2 + 2 \hat{c} \hat{\sigma}_k^2) \sum_{k=0}^{N-1} \tau_k^2. \quad (4.55)
$$

**Proof:** To show part (a), note that by (2.6), (4.33), and (4.53), we have

$$
\|z^{k+1} - z^k\|^2 = a^2 \tau_k^2 \left[ \|\nabla F(x^k) - z^k\|^2 + \|\Delta_k\|^2 - 2 \langle \nabla F(x^k) - z^k, \Delta_k \rangle \right],
$$

and constrained problems, where one can use the quantity $\max(1, \beta_k) \|y^k - x^k\|$ as an online certificate of the quality of the current solution; see, Lemma 1. 

Note that the convergence result of Theorem 4 is established under the boundedness assumption of the second moment of the stochastic gradient. In the remainder of this section, we modify the convergence analysis of Algorithm 2 under a relaxed assumption that only variance of the stochastic gradient is bounded. This assumption, which is common in the literature on smooth stochastic optimization, is stated as follows.
which together with (4.46) and in view of (4.53) implies (4.52). To show part (b), note that by (4.50), (4.51), and similar to the proof of Theorem 2 part (a), we have

\[
\sum_{k=1}^{N} \tau_k^2 \| \nabla F(x^k) - z^k \|^2 \\
\leq \tilde{c} \sum_{k=0}^{N-1} \tau_k^2 \left( \frac{L_{V_f}^2}{a} \| d^k \|^2 + a^2 \tau_k \| \Delta'_k \|^2 + 2a \langle \nabla F(x^{k+1}) - z^k - a \tau_k [\nabla F(x^k) - z^k], \Delta'_k \rangle \right).
\]

Taking conditional expectation from both sides of the above inequality and using (4.53) under Assumption [3] with the choice of \( \tau_0 = 1/a \), we obtain

\[
\sum_{k=0}^{N-1} \mathbb{E}[\| x^k \|^2 | \mathcal{F}_k] \\
\leq \frac{a^2 (L_{V_f} + 2 \tilde{c} \hat{\sigma}_x^2)}{2} \sum_{k=0}^{N-1} \tau_k^2 + \frac{a \hat{c} L_{V_f} L_{f}^2}{2} \sum_{k=0}^{N-1} \tau_k^2 \mathbb{E}[\| d^k \|^2 | \mathcal{F}_{k-1}] + \frac{L_{V_f}}{2} \| \nabla F(z^0) - z^0 \|^2
\]

(with the notation of \( \mathcal{F}_{-1} \equiv \mathcal{F}_0 \)), which together with (4.52) implies (4.55). \( \blacksquare \)

We can now specialize the convergence rate of Algorithm 2 by properly choosing the stepsize policies.

**Theorem 5** Let \( \{x^k, z^k, y^k\}_{k \geq 0} \) be the sequence generated by Algorithm 2 and stepsize set to (3.34) and let

\[
\beta_k \equiv \beta \geq \frac{2(3L_{V_f} + L_{V_f} + \hat{c} L_{V_f} L_{f}^2)}{3} \quad k \geq 0.
\]

If Assumption [3] holds, we have

\[
\mathbb{E}[V(x^R, z^R)] \leq \frac{1}{\sqrt{N}} \left[ \frac{6}{\beta} \left( \max(1, \beta^2) + L_{V_f}^2 \right) \right] \mathbb{E}[V(x^0, z^0)] \\
+ \frac{L_{V_f}}{2} \| \nabla F(x^0) - z^0 \|^2 + (L_{V_f} + 2) \hat{\sigma}_x^2 \| \nabla F(x^0) - z^0 \|^2 + 2 \sigma_x^2 \]

where distribution of \( R \) is still given by (3.32).

**Proof.** First, note that by the choice of stepsize in (3.34), condition (4.54) is satisfied with \( \hat{c} = 1 \). Moreover, by (4.55) and (4.56), we have

\[
\sum_{k=0}^{N-1} \tau_k \mathbb{E}[\| d^k \|^2 | \mathcal{F}_{k-1}] \leq 6 \mathbb{E}[V(x^0, z^0)] + \frac{L_{V_f}}{2} \| \nabla F(x^0) - z^0 \|^2 + (L_{V_f} + 2) \hat{\sigma}_x^2,
\]

\[
\sum_{k=1}^{N} \tau_k \mathbb{E}[\| \nabla F(x^k) - z^k \|^2 | \mathcal{F}_{k-1}] \leq L_{V_f}^2 \sum_{k=0}^{N-1} \tau_k \mathbb{E}[\| d^k \|^2 | \mathcal{F}_k] + 2 \hat{\sigma}_x^2.
\]
Combining the above relations with \(\text{(3.27)}\), we obtain \(\text{(4.57)}\).

While the rate of convergence of Algorithm 2 in \(\text{(4.57)}\) is of the same order as in \(\text{(4.49)}\), the former is obtained under a relaxed assumption on the outputs of the stochastic oracle, as stated in Assumption 3. However, in this case, the stepsize \(\beta_k\) depends on the problem parameters (like in other algorithms for smooth stochastic optimization).

We also have the following asymptotic convergence result.

**Theorem 6** Assume that the sequence of stepsizes satisfy \(\text{(3.41)}\). Then a constant \(\bar{a} > 0\) exists such that, for all \(a \in (0, \bar{a})\), with probability 1, every accumulation point \((x^*, z^*)\) of the sequence \(\{x^k, z^k\}\) generated by Algorithm 2 satisfies the conditions:

\[
z^* = \nabla f(x^*), \quad -z^* \in N_{\mathcal{X}}(x^*).
\]

*Proof.* The analysis follows from [16].

## 5 Concluding Remarks

We have presented a single time-scale stochastic approximation method for smooth nested optimization problems. We showed that the sample complexity bound of this method for finding an approximate stationary point of the problem is in the same order as that of the best-known bound for the stochastic gradient method for single-level stochastic optimization problems. Furthermore, our convergence analysis is the same for both unconstrained and constrained cases and does not require batches of samples per iteration. We also presented a simplified parameter-free variant of the NASA method for single level problems, which enjoys the same complexity bound, regardless of the existence of constraints.
