Communicated by Uwe Kaehler

Abstract. In the slice Hardy space over the unit ball of quaternions, we introduce the slice hyperbolic backward shift operator $S_a$ with the decomposition process

$$f = e_a(f, e_a) + B_a * S_a f,$$

where $e_a$ denotes the slice normalized Szegö kernel and $B_a$ the slice Blaschke factor. Iterating the above decomposition process, a corresponding maximal selection principle gives rise to the slice adaptive Fourier decomposition. This leads to a adaptive slice Takenaka–Malmquist orthonormal system.

Keywords. Adaptive Fourier decomposition, Takenaka–Malmquist system, Slice regular function, Quaternion.

1. Introduction

The purpose of this article is to introduce the quaternionic slice hyperbolic backward shift operators in the slice Hardy space $H^2(B)$ of the unit ball of quaternions. At each step of the process we decompose a function $f \in H^2(B)$ into an orthogonal sum of two functions of which one is in the subspace generated by a slice normalized Szegö kernel $e_a$ and the other is in its orthogonal complement expressed by the Blaschke factor and the backward shift operator $S_a$. By iterating the process we decompose a given function $f \in H^2(B)$ into a slice Takenaka–Malmquist orthonormal system.

*Corresponding author.
Our motivation comes from adaptive Fourier decompositions (AFDs) for the holomorphic Hardy spaces of the unit disc and of a half of the complex plane [21]. The type of decompositions provides approximations by suitable linear combinations of parameterized reproducing kernels in the respective Hardy spaces. The decompositions may result in merely an orthonormal system: It may not be a basis but adaptive to the given signal. It, however, achieves fast decomposition through extracting out the greatest energy portion from the orthogonal remainder at each iterative step. Together with the process there arise the Takenaka–Malmquist (TM) orthonormal systems [24]. If instead of the maximal selection principle one uses a set of parameters satisfying the hyperbolic non-separability rule \( \sum_{k=1}^{\infty} (1 - |a_k|) = \infty \), then the decomposition process results in a TM basis. The Fourier basis \( \{ z^n \}_{n=0}^{\infty} \) is a particular case corresponding to all the parameters \( a_n \) being identically zero. Since Takenaka–Malmquist system consists of rational functions, the study falls into the scope of rational approximation [24]. The Takenaka–Malmquist bases can be thought of hyperbolic versions of the Fourier system. The adaptive Fourier decomposition allows repeating selections of the parameters that offers attainability of the best matching pursuit at each step of parameter selection. The adaptive Fourier decomposition methodology facilitates efficient and thus useful sparse representations. It is, in particular, effective when in the underlying Hilbert space there does exist an approximation theory. Adaptive Fourier decomposition with different contexts has undergone substantial developments [3, 4, 19, 20] with ample applications, such as digital signal processing [18], image processing [17], and system identification [25].

In this paper we establish the slice adaptive Fourier decomposition of slice regular functions over quaternions. It is a higher dimensional extension of the subject in the one complex variable case. The slice regular function theory of quaternions was initiated by Gentili and Struppa [12], and soon developed by a number of researchers. See, for instance [6, 9, 15]. This theory generalizes the holomorphic theory of one complex variable to quaternions. It is remarkable that the slice regular function theory relies on the slice structure of quaternions, which is different from the monogenic function theory over Clifford algebras. The great difference among the slice analysis, Clifford analysis, several complex variables is due to the canonical topology in slice analysis distinct to the Euclidean topology; see [9]. The slice theory shows vigorous vitality in non-commutative Clifford algebra [6], and non-associative real alternative algebras [15, 22]. It also has significant applications in differential geometry [13], geometric function theory [11, 23] and operator theory [2, 5, 7].

To state our main results we provide some preliminaries of the slice Hardy space which are mostly adopted from [1, 2]. Here we introduce an equivalent definition. The slice Hardy space \( H^2(\mathbb{B}) \) over the unit ball of the quaternions consists of the slice regular functions \( f : \mathbb{B} \to \mathbb{H} \) satisfying

\[
\| f \| := \left( \frac{1}{4\pi^2} \int_{\partial \mathbb{B}} \frac{1}{|Im(q)|^2} |f(q)|^2 d\sigma \right)^{1/2} < \infty,
\]
where \( d\sigma \) is the Lebesgue surface measure on \( \partial \mathbb{B} \). The polarization identity of this norm provides \( H^2(\mathbb{B}) \) with an inner product so that it becomes a quaternionic Hilbert space with reproducing kernel. Its normalized reproducing kernel is called the slice normalized Szegő kernel, defined as

\[
    e_a(q) := \sqrt{1 - |a|^2}(1 - qa)^{-*},
\]

for a parameter \( a \in \mathbb{B} \) and any \( q \in \mathbb{B} \), where the \(*\)-product is defined by

\[
    (f * g)(q) = \sum_{n=0}^{\infty} q^n \sum_{k=0}^{n} a_k b_{n-k},
\]

for any two slice regular functions

\[
    f = \sum_{n=0}^{\infty} q^n a_n \quad \text{and} \quad g = \sum_{n=0}^{\infty} q^n b_n,
\]

where all \( a_n, b_n \in \mathbb{H} \). Thus, \( f^{-*} \) denote as the inverse of \( f \) under this \(*\)-product.

Based on the \(*\)-product, we introduce the quaternionic slice hyperbolic backward shift operators \( S_a \), which is uniquely determined by the identity

\[
    f = e_a \langle f, e_a \rangle + B_a * S_a f, \quad (1.1)
\]

for any \( a \in \mathbb{B} \). Here \( B_a \) is the slice Möbius transformation, or an order-1 Blaschke product:

\[
    B_a(q) := (1 - qa)^{-*} \frac{a}{|a|}.
\]

It is noted that the notion of the Hardy spaces and the Blaschke factors in relation to slice regular functions have been introduced and studied by researchers, first appearing in [1], and also others, which are summarized in the book [2].

Iterating the construction in (1.1), we achieve an algebraic relation

\[
    f = \sum_{j=1}^{n} T_j \langle f, T_j \rangle + B_n * (S_{a_n} \circ \cdots \circ S_{a_1} f) \quad (1.2)
\]

for arbitrary \( a_1, \ldots, a_n \in \mathbb{H} \), where we denote

\[
    T_n = B_{n-1} * e_{a_n},
\]

and

\[
    B_n = B_{a_1} * B_{a_2} * \cdots * B_{a_n}.
\]

Here \( \{T_n\}_{j=1}^{n} \) is defined to be the slice Takenaka–Malmquist system which constitutes an slice orthonormal system in \( H^2(\mathbb{B}) \) associated with the non-orthogonal set \( \{e_{a_j}\}_{j=1}^{n} \). Decomposition (1.2) can be restated as a Beurling-Lax type relation:

\[
    H^2(\mathbb{B}) = \text{span}\{T_1, \ldots, T_n\} \oplus B_n * H^2(\mathbb{B}). \quad (1.3)
\]

By applying the maximum selection principle, we obtain the slice AFD for quaternionic slice Hardy space functions.
We point out that the slice Hardy space $H^2(\mathbb{B})$ is a quaternionic Hilbert space and it is non-commutative. In the classical case a TM system is identical with the Gram–Schmidt (GS) orthogonalization applied to the corresponding Szegö kernels. However, in our slice case, the GS process is no longer performable since the product among slice regular functions is now $\ast$-product. This brings challenges in establishing a TM system and obtaining a convergence rate.

The paper is organized as follows. In Sect. 2, we recall some basic concepts and results of slice regular functions and the foundation of the slice Hardy space. In Sect. 3, the slice Takenaka–Malmquist orthonormal system is established. In Sect. 4, We introduce the iterative process, the adaptive selecting process, and prove convergence of the slice adaptive Fourier series. In Sect. 5 a convergence rate result is proved. The case of slice Hardy space of the right half plane is outlined in Sect. 6.

2. Preliminary

2.1. Slice Regular Functions

This paper works on slice regular functions over the non-commutative quaternionic field [14]. Firstly, the quaternionic field $\mathbb{H}$ is linearly generated by an orthogonal basis $\{1, e_1, e_2, e_3 := e_1 e_2\}$ of $\mathbb{R}^4$ with the following multiplication rule:

$$e_i e_j + e_j e_i = -2 \delta_{ij}, \quad i, j = 1, 2, 3,$$

where $\delta_{ij}$ equals 1 if $i = j$ and 0 otherwise.

Now we recall some definitions and results of the slice regular function theory. This theory is based on the slice structure of $\mathbb{H}$, i.e.,

$$\mathbb{H} = \bigcup_{I \in S} C_I,$$

where $S$ denotes the set of imaginary units of $\mathbb{H}$, namely,

$$S := \{q \in \mathbb{H} \mid q^2 = -1\},$$

and $C_I$ denotes the slice of $\mathbb{H}$ made through $I$, i.e.,

$$C_I := \{x + yI, \quad x, y \in \mathbb{R}\}.$$

According to the slice structure, any $q \in \mathbb{H}$ can be written as $q = x + yI$ with $x, y \in \mathbb{R}$ and $I \in S$.

**Definition 2.1.** (slice function) Let $\Omega$ be a set in $\mathbb{H}$, and $f$ a quaternion-valued function defined on $\Omega$ that satisfies

$$f(x + yJ) = \frac{1}{2} \left( f(x + yI) + f(x - yI) \right) + \frac{J J}{2} \left( f(x - yI) - f(x + yI) \right),$$

provided $x, y \in \mathbb{R}$ and $I, J \in S$ such that $x \pm yI$ and $x + yJ$ belong to $\Omega$. Then the function $f$ is said to be a slice function on $\Omega$. 

Definition 2.2. (slice regular function) Let $f$ be a slice function defined on a domain $\Omega \subset \mathbb{H}$. For each $I \in S$, let $\Omega_I := \Omega \cap C_I$ and $f_I := f|_{\Omega_I}$ be the restriction of $f$ to $\Omega_I$. The restriction $f_I$ is said to be holomorphic if it has continuous partial derivatives and
\[
\partial_I f_I(x + yI) = \frac{1}{2}(\partial_x + I\partial_y)f_I(x + yI) = 0.
\]
If for each $I \in S$, $f_I$ is holomorphic in $\Omega_I$, then $f$ is called a slice (left) regular function.

Remark 2.3. Similarly, we can define slice right regular functions.

Lemma 2.4. (splitting) Let $I \in S$ and $\Omega_I$ be open in $C_I$. The function $f_I : \Omega_I \to \mathbb{H}$ is holomorphic if and only if, for all $J \in S$ with $J \perp I$ and every $z = x + yI$, there holds
\[
f_I(z) = F(z) + G(z)J,
\]
where $F, G : \Omega_I \to \mathbb{C}_I$ are complex-valued holomorphic functions of one complex variable.

In the slice regular function theory, under the usual multiplication the product of two slice regular functions is no longer slice regular in general. So there comes the $*$-product.

Definition 2.5. ($*$-product) Let $B$ be the Euclidean unit ball of $\mathbb{H}$. Let $f, g : B \to \mathbb{H}$ be slice regular functions and let $f(q) = \sum_{n \in \mathbb{N}} q^n a_n$, $g(q) = \sum_{n \in \mathbb{N}} q^n b_n$ where $a_n, b_n \in \mathbb{H}$ be their power series expansions. The $*$-product of $f$ and $g$ is the slice regular function defined by \[10\]
\[
(f * g)(q) = \sum_{n \in \mathbb{N}} q^n \sum_{k=0}^n a_k b_{n-k}.
\]
The regular conjugate of $f$ is the slice regular function defined by
\[
f^c(q) = \sum_{n \in \mathbb{N}} q^n \overline{a_n}.
\]
The symmetrization of $f$ is defined to be the function
\[
f^s = f * f^c = f^c * f.
\]
Furthermore, if $f \neq 0$, the regular reciprocal of $f$ is the function defined on $B \setminus Z_{f^s}$ as
\[
f^{-*} = \frac{1}{f^s f^c},
\]
where $Z_{f^s}$ is the zero set of $f^s$.

The $*$-product of two slice regular functions is slice regular and it is related to the usual multiplication through the following relations (see [14], Theorem 3.4):
\[
(f * g)(q) = \begin{cases} f(q)g(\tilde{q}), & \text{if } f(q) \neq 0, \\ 0, & \text{otherwise}, \end{cases}
\]
where \( \tilde{q} = f^{-1}(q)qf(q) \in [q] \) with \([q] \) the symmetry of \( q = x + yI \) defined by
\[
[q] := \{ x + yJ \mid J \in S \}.
\]
Furthermore,
\[
f^{-*} \ast g(q) = f^{-1}(\tilde{q})g(\tilde{q}), \quad \forall q \in B \setminus Zf^*,
\]
where \( \tilde{q} = f^c(q)^{-1}qf^c(q) \in [q] \).

A set \( \Omega \subset \mathbb{H} \) is said to be axially symmetry if for any point \( q \in \Omega \), there holds \([q] \subset \Omega\).

**Definition 2.6.** Let \( \Omega \) be an axially symmetric domain in \( \mathbb{H} \). A slice regular function \( f : \Omega \to \mathbb{H} \) such that \( f(\Omega_I) \subset \mathbb{C}_I \) for all \( I \in S \) is called a slice preserving function.

**Remark 2.7.** If \( f \) is a slice function on an axially symmetric domain \( \Omega \), its symmetrization function \( f^s : \Omega \to \mathbb{H} \) is a slice preserving function.

**Theorem 2.8.** (Cauchy’s formula) Let \( f \) be a slice regular function on an open set \( \Omega \subset \mathbb{H} \). If \( U \) is a bounded axially symmetric open set with \( \overline{U} \subset \Omega \) where \( \overline{U} \) is the closure of \( U \) and if \( \partial U_I \) for \( I \in S \) is a finite union of disjoint rectifiable Jordan curves, then for \( q \in U \),
\[
f(q) = \frac{1}{2\pi} \int_{\partial U_I} (s - q)^{-*}ds_I f(s).
\]
where \( ds_I = -Ids \).

### 2.2. The Foundation of the Slice Hardy Space Over \( B \)

In this subsection, we recall the precondition of the slice Hardy space over the unit ball [2]. Let \( B \) be the Euclidean unit ball of \( \mathbb{H} \) and \( T := \partial B \) its boundary. For any \( I \in S \), denote \( T_I := T \cap \mathbb{C}_I \). Let \( L^2(T_I) \) be the function space consisting of Lebesgue measurable slice functions \( f \) defined on \( T \) for which
\[
\frac{1}{2\pi} \int_0^{2\pi} |f_I(e^{it})|^2 dt < \infty.
\]
The splitting lemma provides a power series expansion of \( f_I \), i.e.
\[
f_I(e^{it}) = \sum_{k=-\infty}^{+\infty} e^{ikt} a_k,
\]
where \( a_k \in \mathbb{H} \) satisfies
\[
\sum_{k=-\infty}^{+\infty} |a_k|^2 < \infty.
\]
For any \( f, g \in L^2(T_I) \), the inner product
\[
\langle \cdot, \cdot \rangle : L^2(T_I) \times L^2(T_I) \to \mathbb{H}
\]
is defined by
\[
\langle f_I, g_I \rangle := \frac{1}{2\pi} \int_0^{2\pi} \overline{g_I(e^{it})} f_I(e^{it}) dt.
\]
It is easy to verify that $\langle \cdot, \cdot \rangle$ is an inner product. i.e. for any $f, g, h \in L^2(T_I)$ and $\lambda, \mu \in \mathbb{H}$, there hold

- $\langle f_I \lambda + g_I \mu, h_I \rangle = \langle f_I, h_I \rangle \lambda + \langle g_I, h_I \rangle \mu$.
- $\langle f_I, f_I \rangle \geq 0$, where the equality holds if and only if $f_I = 0$.

Furthermore, there holds the Cauchy–Schwarz inequality, i.e.

$$\left| \langle f_I, g_I \rangle \right|^2 \leq \langle f_I, f_I \rangle \langle g_I, g_I \rangle.$$  

(2.5)

The power series expansion in (2.3) shows that $L^2(T_I)$ is a right $\mathbb{H}$-module. Thus, $L^2(T_I)$ equipped with the inner product $\langle \cdot, \cdot \rangle$ is a right $\mathbb{H}$-module inner product space.

Denote

$$H^2_+(T_I) := \{ f_I(e^{It}) = \sum_{k=0}^{\infty} e^{ikt} a_k : a_k \in \mathbb{H}, \sum_{k=0}^{\infty} |a_k|^2 < \infty \}.$$  

It is a closed subspace of $L^2(\partial \mathbb{B}_I)$. Recall that the Hilbert transformation

$$\tilde{H} : L^2(T_I) \to L^2(T_I)$$

is defined by

$$\tilde{H} f_I(e^{It}) = \sum_{k=-\infty}^{\infty} (-I) \text{sgn}(k) e^{ikt} a_k,$$

where $a_0$ is the coefficient in formula (2.3). Thus, each $f \in H^2(T_I)$ can be represented as

$$f_I = a_0 + f_I + I \tilde{H} f_I.$$  

In fact, $L^2(T_I)$ has the following direct sum decomposition

$$L^2(T_I) = H^2_+(T_I) \oplus H^2_-(T_I),$$

(2.6)

where

$$H^2_-(T_I) := \{ f_I(e^{It}) = \sum_{k=-\infty}^{-1} e^{ikt} a_k : a_k \in \mathbb{H}, \sum_{k=0}^{\infty} |a_k|^2 < \infty \}.$$  

Thus, the function space $H^2(\mathbb{B}_I)$ with $I \in \mathbb{S}$ is the function space consisting of slice regular functions $f$ defined in $\mathbb{B}$ for which

$$\| f_I \|^2 := \sup_{0 \leq r < 1} \frac{1}{2\pi} \int_0^{2\pi} |f_I(re^{It})|^2 dt < \infty.$$  

For any $f \in H^2(\mathbb{B}_I)$, define its radial limit

$$\hat{f}_I(e^{It}) := \lim_{r \to 1} f_I(re^{It}).$$

(2.7)

The limit $\hat{f}_I$ exists almost everywhere.
Theorem 2.9. Let \( f \in H^2(\mathbb{B}_I) \) for some \( I \in \mathbb{S} \). The radial limit of \( f_I \) exists almost everywhere on \( \mathbb{T}_I \). Furthermore, there is an isometric isomorphism
\[
H^2(\mathbb{B}_I) \rightarrow H^2_+(\mathbb{T}_I)
\]
\[ f \mapsto \hat{f}_I. \]

Remark 2.10. For any slice regular function \( f \) and for any \( I, J \in \mathbb{S} \), \( f_I \in H^2(\mathbb{B}_I) \) if and only if \( f_J \in H^2(\mathbb{B}_J) \).

Remark 2.11. The space \( L^2(\mathbb{T}_I) \) can be expressed as a direct sum of the corresponding Hardy spaces, the latter consisting of boundary limits of well-behaved holomorphic functions. Due to this relation, studies of functions of finite energy may use complex analysis methods. This shows the role and importance of Hardy space theory.

3. Slice Rational Orthogonal System

The slice Hardy space we will introduce in this section is equivalent with the one defined in [2], where the reproducing kernel and Blaschke products of the slice Hardy are also studied. In this section we will introduce the slice rational orthogonal system \( \{T_k\}_{k \geq 1} \), in Theorem 3.6, which is an indispensable part of AFD.

Definition 3.1. The slice Hardy space \( H^2(\mathbb{B}) \) consists of slice regular functions \( f \) defined in \( \mathbb{B} \) which satisfies
\[
\|f\|^2 := \frac{1}{4\pi^2} \int_{\partial \mathbb{B}} \frac{1}{|Im(q)|^2} |f(q)|^2 d\sigma(q) < \infty,
\]
where \( d\sigma \) is the surface area element on \( \partial \mathbb{B} \).

Based on the slice technique and cylindrical coordinate transformation [16], we can polarize (3.1) to one slice as following:
\[
\langle f, g \rangle := \frac{1}{4\pi^2} \int_{T^2} \sin \theta_1 d\theta \int_{\partial \mathbb{B}_I(\theta)} \frac{g(x + I(\theta)y)}{Im(q)|^2} f(x + I(\theta)y) dx dy
\]
\[
= \frac{1}{2\pi} \int_{T^2} \sin \theta_1 d\theta \frac{1}{2\pi} \int_0^{2\pi} g(e^{I(\theta)t}) f(e^{I(\theta)t}) dt
\]
\[
= \frac{1}{2\pi} \int_{T^2} \sin \theta_1 d\theta \langle f_I(\theta), g_I(\theta) \rangle,
\]
where \( \theta = (\theta_1, \theta_2) \in T^2 := [0, \pi]^2 \) and
\[
I(\theta) := (e_1, e_2, e_3) \varphi(\theta) \in \mathbb{S}
\]
with
\[
\varphi(\theta) = \left( \begin{array}{c} \cos \theta_1 \\ \sin \theta_1 \cos \theta_2 \\ \sin \theta_1 \sin \theta_2 \end{array} \right).
\]

Notice that \( H^2(\mathbb{B}) \) is a reproducing kernel quaternionic Hilbert space. For any \( a \in \mathbb{B} \), define the slice normalized Szegö kernel as
\[
e_a(q) := e(a, q) := \sqrt{1 - |a|^2(1 - qa)^{-*}}, \quad \forall \ q \in \mathbb{B},
\]
(3.2)
where $-\ast$ is the regular reciprocal in Definition 2.5. Since $(1 - q\bar{a})^s$ does not have zero points, $e_a$ is a left slice regular function over $\mathbb{B}$. Besides, the property of $\ast$-product shows the general conjugation of $e_a$:

$$e_a(q) = \sqrt{1 - |a|^2} (1 - a\bar{q})^{-\ast}, \quad \forall \ q \in \mathbb{B},$$

which is right conjugate slice regular over $\mathbb{B}$. We claim that $e_a$ is the normalized reproducing kernel of $H^2(\mathbb{B})$. In fact,

$$\langle f, e_a \rangle = \frac{1}{2\pi} \int_0^{2\pi} e_a(e^{it})f(e^{it})dt$$

$$= \frac{\sqrt{1 - |a|^2}}{2\pi} \int_{\partial \mathbb{B}} (1 - ae^{-it})^{-\ast}(e^{-it}(1)de^{it})f(e^{it})$$

$$= \frac{\sqrt{1 - |a|^2}}{2\pi} \int_{\partial \mathbb{B}} (1 - a\bar{q})^{-\ast} \bar{q}(-ids)f(q)$$

$$= \frac{\sqrt{1 - |a|^2}}{2\pi} \int_{\partial \mathbb{B}} (q - a)^{-\ast}(-ids)f(q)$$

$$= \sqrt{1 - |a|^2} f(a),$$

where the third equality holds because the function $g(\bar{q}) = \bar{q}$ is a (right) conjugate slice preserving function so that the $\ast$-product reduces to the usual product. The last equality holds owing to the Cauchy integral formula (i.e. Theorem 2.8). Furthermore, since $\sqrt{1 - |a|^2} f(a)$ is independent of the imaginary unit of $q$, we obtain

$$\langle f, e_a \rangle = \sqrt{1 - |a|^2} f(a).$$

**Remark 3.2.** We claim that the operator $S : L^2(\mathbb{T}) \rightarrow L^2(\mathbb{T})$ defined by

$$Sf(q) := \langle f, e(\cdot, q) \rangle$$

is an orthogonal projection operator from $L^2(\mathbb{T})$ to $H^2(\mathbb{B})$, so $e_a$ with $a \in \mathbb{B}$ is actually the Szegö kernel of $H^2(\mathbb{B})$. In fact, the space decomposition (2.6) shows

$$f = f^+ + f^-,$$

where $f^+ \in H^2_+(\mathbb{T})$ and $f^- \in H^2_-(\mathbb{T})$ and then the Cauchy formula shows

$$Sf(q) = f^+(q) \in H^2(\mathbb{B}).$$

Besides, the conjugate operator of $S$ is

$$S^* f(q) := \langle f, \overline{e(q, \cdot)} \rangle.$$

Since $e(\cdot, q) = \overline{e(q, \cdot)}$, we have

$$S^* = S.$$

Denote the class of slice normalized Szegö kernels as:

$$\mathcal{D} := \{ e_a | a \in \mathbb{B} \}.$$
Theorem 3.3. $\mathcal{D}$ is a dictionary of $H^2(\mathbb{B})$, i.e.
\[
\overline{\text{span}}_{\mathbb{H}} \{ e_a | a \in \mathbb{B} \} = H^2(\mathbb{B}).
\]
Here the left-hand-side represents the closure of the right $\mathbb{H}$-module linear
subspace spanned by finite linear combinations of elements in $\mathcal{D}$.

Proof. If $f \in \overline{\text{span}}_{\mathbb{H}} \{ e_a | a \in \mathbb{B} \}$, then the reproducing property of $e_a$ tells us that
\[
f(a) = 0
\]
for any $a \in \mathbb{B}$. This means $f = 0$. □

Remark 3.4. Notice that for each $I \in S$,
\[
\mathcal{D}_I := \{ e_a | a \in \mathbb{B}_I \}
\]
is also a dictionary of $H^2(\mathbb{B})$ as the definition of slice function shows. However,
its slice Takenaka–Malmquist system given by (3.4) with coefficients in $\mathbb{B}_I$ is
not a basis of $H^2(\mathbb{B})$.

For every $a \in \mathbb{B}$, the Blaschke factor (or the Möbius transformation) $B_a$
is a slice regular function in $\mathbb{B}$ defined as
\[
B_a(q) := (1 - qa)^{-*} (a - q) \frac{a}{|a|}.
\]

Proposition 3.5. [2] Let $a \in \mathbb{B}$. The Blaschke factor $B_a$ has the following properties:
\begin{itemize}
  \item it takes the unit ball $\mathbb{B}$ to itself;
  \item it takes the boundary of the unit ball to itself;
  \item it has a unique zero point $a$.
\end{itemize}

A Blaschke product is defined to be the $*$- product of a finite number
of Blaschke factors (also see ([2])):
\[
B_k(q) := \prod_{j=1}^{k} (1 - qa_j)^{-*} (a_j - q) \frac{a_j}{|a_j|},
\]
where $a_k \in \mathbb{B}$ for any $k \in \{1, 2, \cdots \}$.

In the unit ball $\mathbb{B}$, the slice rational orthogonal system, i.e., the slice
TM system, consists of weighted Blaschke products, i.e. for any $k \geq 1$,
\[
T_k := B_{k-1} * e_{a_k}. \quad (3.4)
\]

Theorem 3.6. $\{ T_k \}_{k \geq 1}$ is an orthonormal system.

Proof. By definition, for any $k \geq 1$ and $I \in S$,
\[
\langle (T_k)_I, (T_k)_I \rangle = \frac{1}{2\pi} \int_{0}^{2\pi} \overline{B_{k-1} * e_k(e^{It})} B_{k-1} * e_k(e^{It}) dt. \quad (3.5)
\]
Equation (2.1) shows
\[
B_{k-1} * e_k(e^{It}) = B_{k-1}(e^{It})e_k(e^{Jt}),
\]
where \( J \in S \) such that \( e^{Jt} = B_k^{-1}(e^{It})e^{It}B_k(e^{It}) \). So equation (3.5) becomes

\[
\langle (T_k)I, (T_k)I \rangle = \frac{1}{2\pi} \int_0^{2\pi} \frac{e_k(e^{Jt})}{e_k(e^{Jt})} B_{k-1}(e^{It})B_{k-1}(e^{It})e_k(e^{It})dt.
\]

Proposition 3.5 implies that

\[
B_{k-1}(e^{It})B_{k-1}(e^{It}) = |B_{k-1}(e^{It})|^2 = 1.
\]

By change of variables, the Cauchy integral formula shows

\[
\langle (T_k)I, (T_k)I \rangle = \frac{1}{2\pi} \int_0^{2\pi} e_k(e^{Jt})e_k(e^{Jt})dt
= \sqrt{1 - |a_k|^2} \int_{\partial \mathbb{B}_J} (q - a_k)^{-*}(-Jds) e_k(q)
= \sqrt{1 - |a_k|^2} e_k(a_k)
= 1.
\]

Since the result is independent of imaginary \( I \), we obtain

\[
\langle T_k, T_k \rangle = 1.
\]

Now we consider the case of different indices with \( 1 \leq l < k \),

\[
\langle (T_k)I, (T_l)I \rangle = \frac{1}{2\pi} \int_0^{2\pi} B_{l-1} * e_l(e^{It})B_{k-1} * e_k(e^{It})dt.
\]

There we reformulate \( B_{k-1} * e_k \) as

\[
B_{k-1} * e_k := B_{l-1} * g,
\]

where

\[
g(q) = \left( \prod_{j=l}^{k-1} (1 - q \bar{a}_j) ^{-*} (a_j - q) \frac{a_j}{|a_j|} \right) e_k(q).
\]

As before,

\[
B_{l-1} * g(e^{It}) = B_{l-1}(e^{It})g(e^{Kt}),
\]

where \( K \in S \) such that \( e^{Kt} = B_l^{-1}(e^{It})e^{It}B_1(e^{It}) \). Notice that

\[
B_{l-1} * e_l(e^{It}) = B_{l-1}(e^{It})e_l(e^{Kt}).
\]

Then equation (3.6) becomes

\[
\langle (T_k)I, (T_l)I \rangle = \frac{1}{2\pi} \int_0^{2\pi} e_l(e^{Kt}) B_{l-1}(e^{It})B_{l-1}(e^{It})g(e^{Kt})dt.
\]

Similarly, we have

\[
|B_{l-1}(e^{It})|^2 = 1.
\]
Again by the change of variables, we apply the Cauchy integral theorem to get
\[
\langle (T_k)_I, (T_l)_I \rangle = \frac{1}{2\pi} \int_0^{2\pi} e^{i(Kt)}g(e^{Kt})dt
\]
\[
= \sqrt{1 - |a|^2} \int_{\partial B_K} (q - a_l)^{-*}(-Kds)g(q)
\]
\[
= \sqrt{1 - |a|^2}g(a_l)
\]
\[
= 0,
\]
which deduces that
\[
\langle T_k, T_l \rangle = 0.
\]
This completes the proof. □

4. Slice Adaptive Fourier Decomposition

In last section, we have introduced a revised slice Hardy space \(H^2(\mathbb{B})\) which is a reproducing kernel quaternionic Hilbert space. Based on this, a slice rational orthogonal system \(T_k\) for any \(k \geq 1\) in the unit ball \(\mathbb{B}\) is established. So, we are ready for the AFD algorithm.

In this section, we intend to adaptively decompose functions in the slice Hardy space into the subspace spanned by \(\{T_k\}_{k \geq 1}\) as following: For any \(f \in H^2(\mathbb{B})\) and \(a_1 \in \mathbb{B}\), there is an equality
\[
f(q) = e_{a_1}(q)\langle f, e_{a_1} \rangle + B_{a_1}^* S_{a_1} f,
\]
where
\[
S_{a_1} f := B_{a_1}^* \left( f(q) - e_{a_1}(q)\langle f, e_{a_1} \rangle \right).
\]
Denote
\[
r_2(q) := f(q) - e_{a_1}(q)\langle f, e_{a_1} \rangle
\]
as the standard remainder and
\[
f_2(q) := S_{a_1} f
\]
as the reduced remainder. By setting \(f_1 = f\), we have
\[
f_1(q) = e_{a_1}(q)\langle f_1, e_{a_1} \rangle + B_{a_1}^* f_2(q).
\]
Notice that \(a_1\) is a removable singularity of \(r_2\). This is because \(a_1\) is a common zero point of function \(r_2\) and Blaschke factor \(B_{a_1}\). In fact, Proposition 3.5 shows \(B_{a_1}\) has the unique zero \(a_1\). Hence, \(f_2\) is a slice regular function in \(\mathbb{B}\). Meanwhile, by the right \(\mathbb{H}\)-linear properties of the inner product \(\langle \cdot, \cdot \rangle\), we have
\[
\langle e_{a_1}(f_1, e_{a_1}), r_2 \rangle = \langle e_{a_1}(f_1, e_{a_1}), f_1 - e_{a_1}(f_1, e_{a_1}) \rangle
\]
\[
= \langle e_{a_1}(f_1, e_{a_1}), f_1 \rangle - \langle e_{a_1}(f_1, e_{a_1}), e_{a_1}(f_1, e_{a_1}) \rangle
\]
\[
= \langle e_{a_1}, f_1 \rangle \langle f_1, e_{a_1} \rangle - \langle f_1, e_{a_1} \rangle \langle e_{a_1}, e_{a_1} \rangle \langle f_1, e_{a_1} \rangle (4.1)
\]
\[
= 0.
\]
This deduces that
\[ \|f_2(q)\|^2 = \|r_2(q)\|^2 = \|f_1(q)\|^2 - |\langle f_1, e_{a_1} \rangle|^2 < +\infty, \]
where the first equality holds as shown in the proof of Theorem 3.6. Thus, we have \( f_2 \in H^2(\mathbb{B}) \).

Now we can apply the iterative process:
\[
f_1(q) = e_{a_1}(q)\langle f_1, e_{a_1} \rangle + B_{a_1} * f_2(q) \]
\[
= e_{a_1}(q)\langle f_1, e_{a_1} \rangle + B_{a_1} * (e_{a_2}(q)\langle f_2, e_{a_2} \rangle + B_{a_2} * f_3(q)) \]
\[
= T_1(q)\langle f_1, e_{a_1} \rangle + T_2(q)\langle f_2, e_{a_2} \rangle + B_{a_1} * B_{a_2} * f_3(q) \]
\[
= T_1(q)\langle f_1, e_{a_1} \rangle + T_2(q)\langle f_2, e_{a_2} \rangle + T_3(q)\langle f_3, e_{a_3} \rangle + B_{a_1} * B_{a_2} * B_{a_3} * f_4(q) \]
\[
= \cdots \]

Theorem 3.6 shows that in the decomposition (1.2) the first \( n \) terms are orthogonal to each other, so we just need to show the orthogonality between each of the \( n \) summed terms and the remainder term. This can be done by following the same method as in the proof of Theorem 3.6.

The orthogonality implies the following energy equality:
\[
\|f_1(q)\|^2 = |\langle f_1, e_{a_1} \rangle|^2 + |\langle f_2, e_{a_2} \rangle|^2 + \cdots + |\langle f_k, e_{a_k} \rangle|^2 + \|f_{k+1}(q)\|^2. \tag{4.3} \]

Now we have had a decomposition of \( f \in H^2(\mathbb{B}) \). The next thing we care about is whether it is convergent and how fast it converges as \( k \to \infty \). Clearly, the answer relies on the choice of \( a_n \). Our purpose is to find a suitable parameter \( a_n \) at every \( n \)-th step such that the corresponding normalized Szegö kernel \( e_{a_n} \) extracts out the largest possible energy portion from the reduced remainder \( f_n \). The premise is that the maximal choice must exist.

**Theorem 4.1.** (maximum selection principle) For any \( f \in H^2(\mathbb{B}) \), there exists an element \( a \in \mathbb{B} \) such that
\[
|\langle f, e_a \rangle| = \max_{b \in \mathbb{B}} |\langle f, e_b \rangle|. \]

**Proof.** We only need to prove that
\[
\lim_{|a| \to 1} |\langle f, e_a \rangle| = \sqrt{1 - |a|^2} |f(a)| = 0. \]
In fact, Theorem 2.9 implies that there exists a polynomial \( g \) defined in the closure of \( \mathbb{B} \) such that
\[
\|f - g\| < \frac{\varepsilon}{2}. \]
The inner product is then divided into two parts:
\[
\langle f, e_a \rangle = \langle f - g, e_a \rangle + \langle g, e_a \rangle. \]
The Cauchy–Schwarz inequality (2.5) implies
\[
|\langle f - g, e_a \rangle| \leq \|f - g\| < \frac{\varepsilon}{2}. \]
Now let $C$ be any but fixed bound of $g$ on the closed unit disc. When $|a|$ is sufficiently close to 1, there follows

$$|\langle g, e_a \rangle| = \sqrt{1 - |a|^2} |g(a)| \leq C \sqrt{1 - |a|^2} < \frac{\varepsilon}{2}.$$  

Combining the above two estimates, the proof is complete. \hfill \Box

**Lemma 4.2.** With the notation $f_n, r_n, T_n, e_{a_n}$ defined in the text for $n \geq 1$ there hold

$$\langle f_n, e_{a_n} \rangle = \langle r_n, T_n \rangle = \langle f, T_n \rangle.$$

**Proof.** For the first equality, recall that

$$r_n = B_{n-1} \ast f_n, \quad T_n = B_{n-1} \ast e_{n}.$$  

Following the proof of Theorem 3.6, we obtain

$$\langle r_n, T_n \rangle = \langle B_{n-1} \ast f_n, B_{n-1} \ast e_{n} \rangle = \langle f_n, e_{a_n} \rangle.$$  

For the second equation, Theorem 3.6 shows

$$\langle T_k, T_n \rangle = 0, \quad 1 \leq k < n.$$  

Hence, the iteration formula (4.2) deduce

$$\langle f, T_n \rangle = \langle r_n, T_n \rangle.$$  

\hfill \Box

**Theorem 4.3.** Let $f \in H^2(\mathbb{B})$. If for every $n \geq 1$, the parameters $a_n$ is chosen according to the maximal selection principle in Theorem 4.1, then

$$f = \sum_{n=1}^{\infty} T_n \langle f_n, e_{a_n} \rangle = \sum_{n=1}^{\infty} T_n \langle f, T_n \rangle.$$  

**Proof.** In the last two sections, we have introduced the slice Hardy space $H^2(\mathbb{B})$ of the slice regular functions over the quaternion field. When equipped with the inner product $\langle \cdot, \cdot \rangle$, it is a quaternionic Hilbert space which is non-commutative. By virtue of the Cauchy formula, we obtained the slice normalized Szegö kernel $\{e_a\}_{a \in \mathbb{B}}$. Together with $e_a$, the slice Blaschke products and $\ast$-product, we established the theory of TM systems $\{T_k\}_{k \geq 1}$ in the slice regular Hardy space. With these preparations and the maximum selection principle we can translate the proof of Theorem 2.2 in [21] word by word to get the counterpart convergence result in the slice regular Hardy space context. \hfill \Box
5. The Convergence Rate

In this section, we prove a convergence rate result for slice adaptive Fourier decomposition. We consider the convergence rate issue in a subclass of $H^2(\mathbb{B})$, defined by:

$$H^2(\mathcal{D}, M) := \{ f \in H^2(\mathbb{B}) : f = \sum_{k=1}^{\infty} e_{b_k} c_k, e_{b_k} \in \mathcal{D}, \sum_{k=1}^{\infty} |c_k| \leq M \},$$

where $\mathcal{D}$ is the dictionary consisting of the slice normalized Szegö kernels and $M$ is a positive constant.

Lemma 5.1. If $f \in H^2(\mathcal{D}, M)$, then $\|f\| \leq M$.

Proof. Since $f \in H^2(\mathcal{D}, M)$, there exist a quaternion series $\{c_k\}_{k \geq 1}$ and a function series $\{e_{b_k}\}_{k \geq 1} \in \mathcal{D}$ such that

$$f = \sum_{k=1}^{\infty} e_{b_k} c_k, \quad \text{with} \quad \sum_{k=1}^{\infty} |c_k| \leq M.$$ 

Thus we obtain

$$\|f\|^2 = |\langle f, f \rangle| = \left| \langle f, \sum_{k=1}^{\infty} e_{b_k} c_k \rangle \right| \leq \sum_{k=1}^{\infty} |\langle f, e_{b_k} \rangle| |c_k| \leq \|f\| \sum_{k=1}^{\infty} |c_k| \leq M \|f\|,$$

where the second inequality holds due to the Cauchy–Schwarz inequality (2.5).

□

Lemma 5.2. [8] Let $A$ be a positive constant and $\{d_m\}_{m=1}^{\infty}$ be a series of non-negative numbers satisfying

$$d_1 \leq A, \quad d_{m+1} \leq d_m \left(1 - \frac{d_m}{A}\right),$$

then for every positive integer $m$, we have

$$d_m \leq \frac{A}{m}.$$ 

Now we can show that the convergence rate is about $O(m^{-1/2})$ in the space $H^2(\mathcal{D}, M)$.

Theorem 5.3. If $f \in H^2(\mathcal{D}, M)$, then

$$\|r_m\| \leq \frac{M}{\sqrt{m}}.$$
Proof. The proof follows the same route as for the classical complex Hardy space. However, we write down the proof since there are details which make it not a direct translation.

Since \( f \in H^2(D, M) \), there exist \( \{c_k\}_{k \geq 1} \in \mathbb{H} \) and \( \{b_k\}_{k=1}^{\infty} \in \mathbb{B} \) such that

\[
f = \sum_{k=1}^{\infty} e_{b_k} c_k, \quad \text{with} \quad \sum_{k=1}^{\infty} |c_k| \leq M. \tag{5.1}
\]

It follows from (4.2), (4.3), and Lemma 4.2 that

\[
\|r_{m+1}\|^2 = \|r_m\|^2 - |\langle f_m, e_{a_m} \rangle|^2 = \|r_m\|^2 - |\langle r_m, T_m \rangle|^2. \tag{5.2}
\]

Now we consider the second term in the right side of equality (5.2). By applying the maximum selection principle of the \( m \)-th step, Lemma 4.2 and the reproducing property of \( e_{a, w} \), we have

\[
|\langle r_m, T_m \rangle| = \sup_{a \in \mathbb{B}} |\langle r_m, T_{\{a_1, \ldots, a_{m-1}, a\}} \rangle|
\]

\[
= \sup_{a \in \mathbb{B}} |\langle f_m, e_a \rangle|
\]

\[
= \sup_{a \in \mathbb{B}} \sqrt{1 - |a|^2} |B_{m-1}^{-1} r_m(a)|
\]

\[
= \sup_{a \in \mathbb{B}} \sqrt{1 - |\hat{a}|^2} |B_{m-1}^{-1}(\hat{a})||r_m(\hat{a})|
\]

\[
\geq \sup_{b_k} \sqrt{1 - |\hat{b_k}|^2} |B_{m-1}^{-1}(\hat{b_k})||r_m(b_k)|
\]

\[
\geq \sup_{b_k} \sqrt{1 - |b_k|^2} |r_m(b_k)|
\]

\[
\geq \sup_{b_k} \sqrt{1 - |b_k|^2} |r_m(b_k)|, \tag{5.3}
\]

where the fourth equality holds because of formula (2.2) with

\[
\hat{a} = B_{m-1}^{c}(a)^{-1} a B_{m-1}^{c}(a) \in [a].
\]

In the first inequality, we consider the set \( \{[b_k]_{k \geq 1}\} \) which is the symmetry of the set \( \{b_k\}_{k \geq 1} \).

We claim that

\[
\sup_{b_k} \sqrt{1 - |b_k|^2} |r_m(b_k)| \geq \frac{1}{M} \|r_m\|^2.
\]

In fact, by applying the orthogonal iterative process of \( f \), we obtain

\[
\langle r_m, r_m \rangle = |\langle r_m, f \rangle - \langle r_m, \sum_{k=1}^{m-1} T_k (f_k, e_{a_k}) \rangle| = |\langle r_m, f \rangle|.
\]
The equation (5.1) and the reproducing property of $e_{b_k}$ give

$$\left| \langle r_m, f \rangle \right| = \left| \langle r_m, \sum_{k=1}^{\infty} e_{b_k} c_k \rangle \right|$$

$$\leq M \sup_{b_k} \left| \langle r_m, e_{b_k} \rangle \right|$$

$$= M \sup_{b_k} \sqrt{1 - |b_k|^2} |r_m(b_k)|,$$

(5.4)

The claim is hence verified.

By substituting (5.4) and (5.3) into equality (5.2), we have

$$\|r_{m+1}\|^2 \leq \|r_m\|^2 \left(1 - \frac{\|r_m\|^2}{M^2}\right).$$

Applying Lemma 5.2, we obtain

$$\|r_m\|^2 \leq \frac{M^2}{m}. \quad \Box$$

6. The Slice Hardy Space Over $\mathbb{H}^+$

The slice Hardy space over $\mathbb{H}^+$ has also been studied in [2]. Again, we use an equivalent definition. Let $H^+$ be the right half plane of $\mathbb{H}$, i.e.

$$H^+ := \{ q \in \mathbb{H} \mid \text{Re}(q) > 0 \}.$$

In this section, we just list the corresponding results of the slice Hardy space over $H^+$, for which the proofs are similar to those for the slice Hardy space over $\mathbb{B}$.

Definition 6.1. The slice Hardy space $H^2(\mathbb{H}^+)$ consists of slice regular functions $f$, which satisfies

$$\|f\|^2 := \frac{1}{2\pi} \int_{T^2} \sin \theta_1 \, d\theta_1 \int_{-\infty}^{+\infty} |f(I(\theta)y)|^2 \, dy < \infty,$$

where $\theta = (\theta_1, \theta_2) \in T^2 = [0, \pi]^2$. Furthermore, $H^2(\mathbb{H}^+)$ is a quaternionic Hilbert space.

Denote by $\langle \cdot, \cdot \rangle$ the inner product with the induced norm $\| \cdot \|$.

For any $a \in \mathbb{H}^+$, the slice normalized Szegö kernel is a left slice regular function over $\mathbb{H}^+$, defined as

$$e_a(q) := \sqrt{\frac{\text{Re}(a)}{\pi}} (q + \bar{a})^{-*},$$

where $-*$ is the regular reciprocal in Definition 2.5 and $\text{Re}(a)$ is the real part of $a \in \mathbb{H}$. Then $e_a$ is a reproducing kernel of $H^2(\mathbb{H}^+)$, i.e.

$$\langle f, e_a \rangle = \sqrt{4\pi \text{Re}(a)} f(a).$$

(6.1)
Besides, the slice normalized Szegö kernel $e_\alpha$ is a dictionary of $H^2(\partial \mathbb{H}^+)$, i.e.
$$\text{span}_\mathbb{H} \{e_\alpha | \alpha \in \mathbb{H}\} = H^2(\partial \mathbb{H}^+),$$

The Blaschke product is
$$B_k(q) := \prod_{j=1}^{k} (q + \bar{a}_j)^{-*} (q - a_j),$$
where $a_k \in \mathbb{H}_+$ for any $k \in \{1, 2, \cdots \}$.

In the right half plane $\mathbb{H}_+$, the slice rational orthogonal system (i.e. the slice Takenaka–Malmquist system) consists of weighted Blaschke product, i.e. for any $k \geq 1$,
$$T_k := B_{k-1} * e_k.$$

**Theorem 6.2.** $\{T_k\}_{k \geq 1}$ is a normal orthogonal system, i.e.
$$\begin{align*}
\langle T_k, T_k \rangle &= 1, \quad k \geq 1, \\
\langle T_k, T_l \rangle &= 0, \quad 1 \leq l < k.
\end{align*}$$

Now we consider the slice adaptive Fourier decomposition. For any $f \in H^2(\mathbb{H}^+)$ and $a_1, a_2, a_3 \cdots \in \mathbb{H}^+$, there is an iterative process:

$$f_1(q) = e_{a_1}(q) \langle f_1, e_{a_1} \rangle + B_{a_1} * f_2(q)$$
$$= e_{a_1}(q) \langle f_1, e_{a_1} \rangle + B_{a_1} * (e_{a_2}(q) \langle f_2, e_{a_2} \rangle + B_{a_2} * f_3(q))$$
$$= T_1(q) \langle f_1, e_{a_1} \rangle + T_2(q) \langle f_2, e_{a_2} \rangle + B_{a_1} * B_{a_2} * f_3(q)$$
$$= T_1(q) \langle f_1, e_{a_1} \rangle + T_2(q) \langle f_2, e_{a_2} \rangle + B_{a_1} * B_{a_2} * (e_{a_3}(q) \langle f_3, e_{a_3} \rangle + B_{a_3} * f_4(q))$$
$$f_1(q) = T_1(q) \langle f_1, e_{a_1} \rangle + T_2(q) \langle f_2, e_{a_2} \rangle + T_3(q) \langle f_3, e_{a_3} \rangle + B_{a_1} * B_{a_2} * B_{a_3} * f_4(q)$$
$$= \cdots$$

Orthogonality of the Takenaka–Malmquist system $\{T_k\}_{k \geq 1}$ implies the following energy relation:
$$|f_1(q)|^2 = |\langle f_1, e_{a_1} \rangle|^2 + |\langle f_2, e_{a_2} \rangle|^2 + \cdots + |\langle f_k, e_{a_k} \rangle|^2 + |f_{k+1}(q)|^2.$$

**Theorem 6.3.** For any $f \in H^2(\mathbb{H}^+)$, there exists an element $a \in \mathbb{H}^+$ such that
$$|\langle f, e_a \rangle| = \max_{b \in \mathbb{H}^+} |\langle f, e_b \rangle|.$$ 

**Theorem 6.4.** Let $f \in H^2(\mathbb{H}^+)$. If for every $n \geq 1$ the parameters $a_n$ in relation to the reduced remainder function $f_n$ is chosen according to Theorem 6.3, then
$$f = \sum_{n=1}^{\infty} T_n \langle f, e_{a_n} \rangle = \sum_{n=1}^{\infty} T_n \langle f, T_n \rangle.$$ 

Denote
$$H^2(\mathcal{D}, M) := \{f \in H^2(\mathbb{H}^+) : f = \sum_{k=1}^{\infty} e_{b_k} c_k, \quad e_{b_k} \in \mathcal{D}, \quad \sum_{k=1}^{\infty} |c_k| \leq M\},$$
where $\mathcal{D}$ is the dictionary consisting of the slice normalized Szegö kernels and $M$ is a positive constant. Then we have the following
Theorem 6.5. If $f \in H^2(\mathcal{D}, M)$, then
\[ \|r_m\| \leq \frac{M}{\sqrt{m}}. \]
