THE 3x + 1 SEMIGROUP

DAVID APPLEGATE AND JEFFREY C. LAGARIAS

Abstract. The 3x + 1 semigroup is the multiplicative semigroup $S$ of positive rational numbers generated by $\{\frac{4k+1}{3k+2} : k \geq 0\}$ together with $\{2\}$. This semigroup encodes backwards iteration under the 3x + 1 map, and the 3x + 1 conjecture implies that it contains every positive integer. This semigroup is proved to be the set of positive rationals $\frac{a}{b}$ in lowest terms with $b \not\equiv 0 \pmod{3}$, and so contains all positive integers.

1. Introduction

The 3x + 1 problem concerns the behavior under iteration of the 3x + 1 function $T : \mathbb{Z} \to \mathbb{Z}$ given by

$$T(n) = \begin{cases} \frac{n}{2} & \text{if } n \equiv 0 \pmod{2} \\ \frac{3n+1}{2} & \text{if } n \equiv 1 \pmod{2} \end{cases}$$

The 3x + 1 Conjecture asserts that for each $n \geq 1$, some iterate $T^{(k)}(n) = 1$. This is a notoriously hard problem, work on which is surveyed in Lagarias [2] and Wirsching [8]. It has been verified for all $n < 2.8 \times 10^{17}$ (see Oliveira e Silva [4] and Roosendaal [6]) but remains unsolved.

Recently H. Farkas [1] proposed an interesting weakening of the 3x + 1 problem, as follows. Let $S$ denote the multiplicative semigroup of positive rational numbers generated by $\{\frac{n}{T(n)} : n \geq 0\}$, i.e. by 2 and by $\{\frac{2k+1}{3k+2} : k \geq 0\}$. We call $S$ the 3x + 1 semigroup, and write

$$S := \langle \frac{1}{2}, \frac{3}{5}, \frac{5}{8}, \frac{7}{11}, \ldots \rangle.$$ 

H. Farkas formulated the following conjecture.
**Weak 3x+1 Conjecture.** The 3x+1 semigroup $S$ contains every positive integer.

The semigroup $S$ encodes inverse iteration by the 3x+1 function. That is, the semigroup $S$ contains $1 = 2 \cdot \frac{1}{2}$, and has the property that if $T(n) \in S$, then also $n \in S$, because each $\frac{n}{T(n)}$ is a generator of $S$. It follows that if the 3x+1 iteration eventually takes $n$ to 1, then $n$ belongs to $S$. Thus the 3x+1 conjecture implies the weak 3x+1 conjecture.

The weak 3x+1 conjecture appears a potentially easier question to resolve than the 3x+1 conjecture, since the semigroup $S$ permits some representations of integers as products of generators not corresponding to 3x+1 iteration. Indeed, the object of this paper is to prove the following result characterizing all elements of the 3x+1 semigroup, which implies the weak 3x+1 conjecture.

**Theorem 1.1.** The 3x+1 semigroup $S$ equals the set of all positive rationals $\frac{a}{b}$ in lowest terms having the property that $b \not\equiv 0 \pmod{3}$. In particular, it contains every positive integer.

In order to prove this result, we shall need to study the inverse semigroup $W := S^{-1}$ generated by $\{ \frac{T(n)}{n} : n \geq 1 \}$, i.e. by $\frac{1}{2}$ and by $\{ \frac{3k+2}{2k+1} : n \geq 0 \}$. That is,

$$W := S^{-1} = \langle \frac{1}{2}, \frac{2}{1}, \frac{5}{3}, \frac{8}{5}, \ldots \rangle.$$ 

We call this semigroup the *wild semigroup*, following the terminology used in a paper [3] of the second author, which was inspired by the novel “The Wild Numbers” ([7]). The paper [3] formulated the following conjecture.

**Wild Numbers Conjecture.** The integers in the wild semigroup $W$ consist of all integers $m \geq 1$ with $m \not\equiv 0 \pmod{3}$. Equivalently, the 3x+1 semigroup $S$ contains all unit fractions $\frac{1}{m}$ such that $m \not\equiv 0 \pmod{3}$.

Theorem [1.1] is equivalent to the truth of both the weak 3x+1 conjecture and the wild numbers conjecture. In [3] the two conjectures were shown to be equivalent,
so to deduce Theorem 1.1 it would suffice to prove either one of them separately. However in the approach taken here we consider them together, and prove them simultaneously using an inductive method in which the truth of the conjectures to given bounds implies their truth to a larger bound. We use a see-saw method that increases the bound first of one, then the other.

In §2 we show the relevance of the 3x + 1 iteration to the weak 3x + 1 conjecture. This is the new ingredient introduced here relative to [3]. In §3 we then prove properties of integers in $W$ and in §4 we complete the argument for Theorem 1.1.

2. Modified 3X + 1 iterations

To prove the weak 3x + 1 conjecture by induction on the size of the integer $m$, it would suffice to prove that under forward iteration of the 3x + 1 map starting at a given $m \geq 2$, we eventually arrive at a smaller integer $m'$, which would belong to the semigroup $S$ by the induction hypothesis. The sequence of reverse 3x + 1 iterates going from $m'$ back to $m$ are multiplications by elements of $S$, and this would establish that $m \in S$. However, if this argument could be carried out, it would prove more, namely the 3x + 1 conjecture itself. Since this problem seems out of reach, we considered a modification of this approach.

We take advantage of the fact that the 3x + 1 iteration decreases “almost all” integers, in the sense of [2, Theorem A]. We recall that forward iteration of the 3x + 1 function $T(\cdot)$ for $j$ steps is known to decrease the value of an integer $n$ in most congruence classes $n \pmod{2^j}$. Recall that the first $j$ steps of the 3x + 1 iteration are uniquely determined by the class $n \pmod{2^j}$ and that every symbol pattern of even and odd integers of length $j$ occurs in some trajectory of length $j$, cf. Lagarias[2, Theorem B]. A residue class $s \pmod{2^j}$ is said to have a strong stopping time $k \leq j$ if the smallest integer $s \geq 2$ in the residue class decreases after $k$ steps of iteration. This property is then inherited by all members $\geq 2$ of the residue class. As $j$ increases the fraction of integers not having a strong stopping time goes to zero, but there still remain exponentially many residue classes $(\pmod{2^j})$ not having this decreasing property ([2, Theorems C and D]).
The semigroup $\mathcal{S}$ permits the possibility of going “uphill” by taking an initial value $n$ to a value $mn$ via some integer multiplier $m$, provided $m \in \mathcal{S}^{-1} = \mathcal{W}$. That is, if $\frac{1}{m} \in \mathcal{S}$ and if we know $mn \in \mathcal{S}$ then we may deduce $n = \frac{1}{m} \cdot mn \in \mathcal{S}$.

We pay a price in going “uphill” of increasing the initial size of the integer, but in doing so we may move from a “bad” residue class $s \pmod{2^j}$ to a “good” residue class $ms \pmod{2^j}$ which under iteration results in such a large decrease in the size of the number that it overcomes the added multiplicative factor $m$ and arrives at an integer smaller than $n$ in $\leq j$ steps. One can use this procedure only for $j$ steps ahead because the members of the residue class only possess the same symbolic dynamics for $j$ steps, and we wish the property of decrease to hold for all members of the residue class. If so, we can carry out the induction step for all integers in this particular “bad” residue class $s \pmod{2^j}$. Another variation of this idea is to multiply by various $m$‘s in the middle of the first $j$ steps of the iteration; there is no reason why the multiplication must be done only at the first step, one may still gain by switching the residue class in the middle of the iteration.

One can now ask: is there a finite $j$ and a finite list $\{m_1, m_2, \cdots, m_r\}$ of integer elements in $\mathcal{W}$ such that suitable multiplications by elements of this list will decrease elements in every residue class $\pmod{2^j}$ in this fashion? If so, this would yield a proof of the weak $3x + 1$ conjecture by induction on $n$.

This approach comes very close to succeeding, but there is an obstruction that in principle prevents it from succeeding. We found by computer search, for small values of $j$, multiplier lists that established decrease for every residue class $\pmod{2^j}$ except for the class $-1 \pmod{2^j}$. These searches revealed that the class $-1 \pmod{2^j}$ resisted elimination for $12 \leq j \leq 30$. We then looked for and found the following proof that the class $-1 \pmod{2^j}$ can never be eliminated by this method. The iterates of a positive integer $n$ in the congruence class $-1 \pmod{2^j}$ will behave exactly the same way as $-1$ does for the first $j$ steps, allowing multipliers. We may write the $j$-th iterate of $-1$ obtained using multipliers as $m_1 m_2 \cdots m_j a(-1) + b$, in which $m_k$ is the multiplier used at the $k$-th step (we allow $m_k = 1$), $a$ is a power of $3$, and $b$ is a positive integer. For this multiplier sequence any $n \equiv -1 \pmod{2^j}$ will map
to \( \frac{m_1 m_2 \cdots m_j a + b}{2^j} \) after \( j \) steps. However we must have

\[
\frac{(m_1 m_2 \cdots m_j) a (-1) + b}{2^j} \leq -1,
\]

because all iterates of \(-1\), times multipliers, remain negative. Rearranging this inequality gives

\[
(m_1 m_2 \cdots m_j) a \geq 2^j + b.
\]

Now, for positive \( n \), multiplying both sides by \( \frac{n}{2^j} \) yields

\[
\frac{(m_1 m_2 \cdots m_j) a n + b}{2^j} \geq n + \frac{b(n + 1)}{2^j} > n.
\]

It follows that decrease cannot have occurred after \( j \) steps, and an argument for no decrease at any intermediate step is similar.

We conclude that to get an inductive proof of the weak \( 3x + 1 \) conjecture along these lines, a new method will be needed to handle integers in the “bad” congruence class \(-1 \pmod{2^j}\), and it will be necessary to consider an infinite set of multipliers in \( W \).

We now prove the decrease mentioned above for all residue classes \((\text{mod } 4096)\) except the class \(-1 \pmod{4096}\), using a fixed finite set \( H \) of multipliers given below; these are residue classes \((\text{mod } 2^j)\) for \( j = 12 \). In what follows it will be important that the decrease is by a constant factor strictly smaller than one. In §3 we will verify the hypothesis \( H \subset W \) made in this lemma.

**Lemma 2.1.** If \( H = \{5, 7, 11, 13, 23, 29, 43\} \subset W \), then for every integer \( x > 1 \) with \( x \not\equiv -1 \pmod{4096} \) there exists \( s \in W \) such that \( sx \in \mathbb{Z} \) and \( sx \leq \frac{76}{73} x \).

**Proof.** This is established case by case in Tables 1 and 2. Every path shown consists of iterations of \( T(\cdot) \) and multiplications by integers in \( H \), and thus consists of iterations of multiplications by elements of \( W \). The iteration takes \( k \) steps, where \( k \) is the given number of bits, and for integers \( n \) in the class \( s \pmod{2^k} \), one has

\[
T^{(k)}(n) = c(s)n + d(s),
\]

with

\[
c(s) = \frac{3^l m_1 m_2 \cdots m_k}{2^k},
\]

Table 2. Decreasing weak $3x + 1$ paths, for $x \equiv 15 \mod 16$. 
in which the \( m_i \) are the multipliers at each step and \( l \) is the number of odd elements in the resulting trajectory, and \( d(s) \geq 0 \). The quantity \( c(s) \) is the “asymptotic ratio” reported in the second column of the tables.

The “class bits” presented in these tables are binary strings comprising the binary expansion of the residue class written in reverse order. The set of these binary strings together form a prefix code which by inspection certifies that every residue class \((\text{mod } 4096)\) is covered except \(-1 \pmod{4096}\). The data on the far right in the table gives the action on the smallest positive element in the congruence class (resp. second smallest element for the class containing \( n = 1 \)). In each case the factor of decrease on all elements of the progression (excluding the element \( n = 1 \)), reported as the “worst-case ratio” in the table, is that given by the decrease on this particular element.

\[ \square \]

To deal with the residue class \(-1 \pmod{2^j}\), we next show that there always exists a simple (but infinite) sequence of multipliers having the property that, starting from \( n \equiv -1 \pmod{2^j} \), with \( n > 0 \) one arrives at a final integer \( n' \) that is only slightly larger than the initial starting point \( n \). We will later make use of this to eliminate the congruence class \(-1 + 2^j \pmod{2^{j+1}}\), in an induction on \( j \).

**Lemma 2.2.** Let \( x, k, \) and \( j \) be positive integers such that \( x \equiv -1 \pmod{2^k} \), with \( 1 \leq j \leq k \) and \( j \equiv 1, 5 \pmod{6} \). Then the multiplier \( m = \frac{2^{j+1}}{3} \) is an integer satisfying \( m \equiv 1, 5 \pmod{6} \), with the property that the \( j \)-th iterate of \( mx \) satisfies the bound

\[
T^j(mx) = x + \frac{x + 1}{2^j} \leq \frac{2^j + 2}{2^j} x,
\]

and \( T^j(mx) \equiv -1 \pmod{2^{k-j}} \). If in addition \( x \not\equiv -1 \pmod{2^{k+1}} \), then \( T^j(mx) \not\equiv -1 \pmod{2^{k+1-j}} \).

**Proof.** Since \( j \equiv 1, 5 \pmod{6} \), \( 2^j \equiv 2, 5 \pmod{9} \), so \( m = \frac{2^{j+1}}{3} \) is an odd integer and \( m \not\equiv 0 \pmod{3} \). Since \( mx \equiv -m \pmod{2^k} \), \( mx \) is odd, so

\[
T(mx) = \frac{3mx + 1}{2} = \frac{2^j x + x + 1}{2}.
\]
THE 3x + 1 SEMIGROUP

Since $x \equiv -1 \pmod{2^k}$ and $k \geq j$, $2^j x + x + 1 \equiv 0 \pmod{2^j}$. Thus

$$T^j(mx) = \frac{2^j x + x + 1}{2^j} = x + \frac{x + 1}{2^j}.$$

$$\frac{x + 1}{2^j} \equiv 0 \pmod{2^{k-j}}$$

so $T^j(mx) \equiv -1 \pmod{2^{k-j}}$. If in addition $x \not\equiv -1 \pmod{2^{k+1}}$, then $\frac{x + 1}{2^j} \not\equiv 0 \pmod{2^{k+1-j}}$, so $T^j(mx) \neq -1 \pmod{2^{k+1-j}}$. \qed

To make use of Lemma 2.2 in an inductive proof, we need to establish that after using it on $n$ to obtain $n' = T^j(n)$ a single $3x + 1$ iteration applied to $n'$ produces an integer $n''$ smaller than $n$. This is the aim of the following lemma, which gives an inductive method of eliminating the class $-1 + 2^j \pmod{2^{j+1}}$ using a suitable integer multiplier $m$, assuming that $m$ is a wild integer.

**Lemma 2.3.** Suppose $H \subset W$. Let $x \equiv -1 \pmod{2^k}$ and $x \not\equiv -1 \pmod{2^{k+1}}$, for a fixed $k \geq 12$. Now choose $j$ so that $j \equiv 1 \pmod{6}$ and $k - 10 \leq j \leq k - 5$. Then $m = (2^j + 1)/3$ is an integer, and if $m \in W$, then there exists $s \in W$ such that $sx \in \mathbb{Z}$ and $sx \leq \frac{1235}{1264} x$.

**Proof.** First, note that for all $k \geq 12$, since $j \equiv 1 \pmod{6}$ and $j \geq k - 10 \geq 2$, we have $j \geq 7$. From Lemma 2.2, $m \in \mathbb{Z}$ and $T^j(mx) = x + \frac{x + 1}{2^j}$, so there exists $s_1 \in W$ such that $s_1 mx \in \mathbb{Z}$, $s_1 mx = x + \frac{x + 1}{2^j}$, $s_1 mx \equiv -1 \pmod{2^{k-j}}$, and $s_1 mx \not\equiv -1 \pmod{2^{k+1-j}}$. But $k - j \leq 10$, so $s_1 mx \not\equiv -1 \pmod{2^{11}}$. Thus from Lemma 2.2 there exists $s_2 \in W$ such that $s_2(s_1 mx) \in \mathbb{Z}$ and $s_2(s_1 mx) \leq 76/79(s_1 mx)$. Now $j \geq 7$ and the bound of Lemma 2.2 gives

$$x + \frac{x + 1}{2^j} \leq \frac{2^j + 2}{2^j} x \leq \frac{130}{128} x,$$

so that $s_2 s_1 mx \leq \frac{76}{79} \frac{130}{128} x = \frac{1235}{1264} x$. \qed

3. **Wild Integers**

The wild integers are the integers in the wild semigroup $W$. The “multiplier” approach begun in §2 required the use of multipliers that are wild integers, and indicated that in taking this approach one would need to consider an infinite set of multipliers. This in turn seems to require understanding the complete structure.
of the integer elements in \( W \), which leads to investigation of the wild numbers conjecture.

In this section we establish properties of wild integers, giving criteria for establishing their existence. We first show that the elements in \( H \) in \( \S 2 \) are wild integers. Here we write \( g(n) = \frac{3n+2}{2n+1} \).

**Lemma 3.1.** The set \( H = \{5, 7, 11, 13, 23, 29, 43\} \) is contained in the wild semigroup \( W = S^{-1} \).

**Proof.** Table 3 below gives certificates showing that the elements in \( H \) belong to \( W \), representing them in terms of the generators of \( W \). The table uses the notation \( g(n) = \frac{3n+2}{2n+1} \), for \( n \geq 1 \). Aside from \( p = 5 \), these identities were found by computer search by Allan Wilks, see \( \S 2 \) of [3]. \( \square \)

The following lemma uses the truth of the weak \( 3x + 1 \) conjecture on an initial interval to extend the range on which the wild numbers conjecture holds.

**Lemma 3.2.** Suppose that the weak \( 3x + 1 \) conjecture holds for \( 1 \leq n \leq 2^j - 2 \) and that the wild numbers conjecture holds for \( 1 \leq m \leq 2^j - 1 \), with \( j \geq 16 \). Then the wild numbers conjecture holds for \( 1 \leq m \leq 2^{j+1} - 1 \).

**Proof.** It suffices to prove that every prime \( q \) with \( \frac{2^j - 1}{189} < q \leq \frac{2^{j+1} - 1}{189} \) lies in \( W \). Proceeding by induction on increasing \( q \), we may assume every prime \( p \) with \( 3 < p < q \) lies in \( W \). It now suffices to prove: There exists a positive integer \( n \leq 2^j - 2 \) with \( nq \in W \). For if so, then the induction hypothesis implies that \( n \in S \) so that \( q = \frac{1}{n} \cdot nq \in W \). In establishing this we will consider only those \( n \) such that \( nq \equiv -1 \pmod{9} \). Then \( nq = 3l + 2 \) for some positive integer \( l \), and \( nq = t \cdot (2l + 1) \) where \( t = \frac{3l+2}{2l+1} \in W \). Thus it will suffice to show \( 2l + 1 \in W \).

To carry this out, define \( a \) as the least positive residue with \( aq \equiv -1 \pmod{9} \), so that \( 0 < a < 9 \). For \( n \) in the arithmetic progression \( n = 9k + a \), setting \( nq = 3l + 2 \), we have

\[
2l + 1 = 2\left(\frac{nq-2}{3}\right) + 1 = \frac{2}{3}((9k + a)q - 2) + 1 = 6qk + r, \quad \text{with} \quad r := \frac{2aq - 1}{3}.
\]
Then every integer \( k \) needs to find a suitable value of \( \gcd(r, q) \equiv 1 \pmod{6} \). Let \( \Sigma \) denote the set of 6-smooth integers. For each prime \( q \) there exists an integer \( 1 \leq q \leq 6q \) such that \( 6qk + r \in \mathcal{W} \).

Define a positive integer to be \( q \)-smooth if all its prime factors are smaller than \( q \). Let \( \Sigma_q \) denote the set of \( q \)-smooth integers \( s \) with \( 0 < s < 6q \) and \( \gcd(s, 6q) = 1 \). Then every \( s \in \Sigma_q \) is a product of primes \( p \) with \( 5 \leq p < q \), and the induction
hypothesis implies that \( s \in W \).

**Claim.** If \( q \geq 256 \) then \( |\Sigma_q| > q - 1 \).

Assuming the claim is true, we can apply it in our situation because \( q > 2^{15.1/189} \geq 2^{16.1/189} > 346 \). The claim implies that \( \Sigma_q \) contains more than half of the invertible residue classes (mod \( 6q \)), since \( \phi(q) = 2(q-1) \). Therefore in the group of invertible residue classes (mod \( 6q \)), the sets \( \Sigma_q \) and \( r \cdot \Sigma_q^{-1} \) must meet, since each contains more than half of the classes. Therefore \( s_1 \equiv r \cdot s_2^{-1} \pmod{6q} \), for some \( s_1, s_2 \in \Sigma_q \).

Now \( s_1 s_2 \equiv r \pmod{6q} \), and we may define \( k \geq 0 \) by setting \( s_1 s_2 = 6qk + r \). Since each \( s_i \in \Sigma_q \subseteq \mathbb{W} \) we have \( 6qk + r \in \mathbb{W} \). Since \( s_1, s_2 < 6q \) we find that \( k < 6q \), as required. Thus the proof of Lemma 3.2 will be complete once the claim is established.

To prove the claim, since \( \phi(6q) = 2q - 2 \) we may reformulate it as the assertion: **there are at most** \( q - 2 \) **invertible residue classes below** \( 6q \) **which are not** \( q \)-**smooth.**

The non-\( q \)-smooth numbers below \( 6q \) relatively prime to \( q \) consist of the primes \( q' \) with \( q < q' < 6q \) together with the integers \( 5q' \) where \( q' \) is prime with \( q < q' < 6q \).

Thus we must show that for \( q > 256 \),

\[
(2) \quad (\pi(6q) - \pi(q)) + \pi(6q) - \pi(q) \leq q - 2.
\]

The left side of (2) is \( O(\frac{x}{\log x}) \) by the prime number theorem, so (2) holds for all sufficiently large \( q \); it remains to establish the specific bound. We use explicit inequalities for prime counting functions due to Rosser and Schoenfeld [5, Theorems 1 and 2], which state that for all \( x \geq 17 \),

\[
(3) \quad \frac{x}{\log x} < \pi(x) < \frac{x}{\log x - \frac{3}{2}},
\]

and also that, for all \( x \geq 114 \),

\[
\pi(x) < \frac{5}{4} \frac{x}{\log x}.
\]

The first of these inequalities gives

\[
\pi(6x) \leq \frac{6x}{\log(6x) - \frac{3}{2}} \leq \frac{6x}{\log x}
\]
since $\log 6 \geq \frac{3}{2}$. The second gives, for $x \geq 256$,

$$\pi(\frac{6}{5}x) < \frac{5}{4} \left( \frac{\frac{6}{5}x}{\log(\frac{6}{5}x)} \right)$$

$$< \frac{3}{2} \frac{x}{\log x} \left( \frac{\log x + \log \frac{6}{5}}{\log x + \log \frac{6}{5}} \right)$$

$$< \frac{3}{2} \frac{x}{\log x} \left( 1 - \frac{1}{\log x + \log \frac{6}{5}} \right)$$

$$< \frac{3}{2} \frac{x}{\log x} - 2,$$

where we used $\log \frac{6}{5} > \frac{1}{5}$, and $x \geq 256$ was used at the last step. Combining these bounds gives, for $x \geq 256 > e^{11/2}$,

$$\pi(6x) + \pi(\frac{6}{5}x) - 2\pi(x) < \frac{11}{2} \frac{x}{\log x} - 2 \leq x - 2,$$

which proves the claim. \qed

4. COMPLETION OF PROOFS

Proof of Theorem 1.1. The theorem is equivalent to the truth of the weak $3x + 1$ conjecture and the wild numbers conjecture. Together these two conjectures imply that the semigroup $S$ contains all rationals $\frac{a}{b} = a \cdot \frac{1}{b}$ with $b \not\equiv 0 \pmod{3}$. However $S$ contains no rational $\frac{a}{b}$ in lowest terms with $b \equiv 0 \pmod{3}$, because no generator of $S$ contains a multiple of 3 in its denominator. Conversely, if $S$ contains all such rationals, then both conjectures hold.

We prove the weak $3x + 1$ conjecture and wild numbers conjecture simultaneously by induction on $k \geq 12$, using the following three inductive hypotheses.

(1) For each integer $x > 1$ with $x \not\equiv -1 \pmod{2^k}$ there is an element $s \in W$ such that $sx$ is an integer and $sx \leq \frac{1235}{1264}x$.

(2) The weak $3x + 1$ conjecture is true for $1 \leq n \leq 2^k - 2$.

(3) The wild integers conjecture is true for $1 \leq m \leq \frac{4^k - 1}{189}$.

We treat the induction step first, and the base case afterwards. We suppose the inductive hypotheses hold for some $k \geq 12$, and must show show they then hold for $k + 1$. 
Hypotheses (2) and (3) for $k$ permit Lemma 3.2 to apply, whence for $k \geq 16$ we conclude that inductive hypothesis (3) holds for $k+1$. For the remaining cases $12 \leq k \leq 15$ we verify inductive hypothesis (3) for $k+1$ directly by computation, which is included in the base case below.

Inductive hypothesis (1) for $k$ gives that all elements smaller than $2^{k+1} - 1$ except possibly $2^k - 1$ can be decreased by multiplication by an element of $W$ to a smaller integer. We wish to apply Lemma 2.3 to show that all elements in the congruence class $-1 + 2^k \pmod{2^{k+1}}$ can also be decreased by multiplication by an element of $W$ to an integer smaller by the multiplicative factor $\frac{1235}{1264}$. First, Lemma 3.1 shows that the elements of $H$ belong to $W$, establishing one hypothesis of Lemma 2.3. Second, the other multiplier $m = \frac{2^j + 1}{3}$ in the hypothesis of Lemma 2.3 has $j = k - 5 - (k \pmod{6})$, and satisfies $m \leq \frac{2^{(k+1)-6}+1}{3} \leq \frac{2^{k+1}-1}{189}$, so $m \in W$ by inductive hypothesis (3), which is already established to hold for $k+1$. Thus all the hypotheses of Lemma 2.3 are satisfied, and its conclusion verifies the inductive hypothesis (1) for $k+1$.

Next, inductive hypothesis (1) for $k+1$ establishes the decreasing property for all integers $1 < n \leq 2^{k+1} - 2$, hence the weak $3x+1$ conjecture follows for all integers in this range. This verifies inductive hypothesis (2) for $k+1$, and so completes the induction step.

It remains to treat the base case, which is $k = 12$ for hypotheses (1) and (2), and $k = 16$ for hypothesis (3). For $k = 12$ inductive hypothesis (1) is verified by Lemma 2.1. The inductive hypothesis (2) for $k = 12$ is verified by the fact that the $3x+1$ conjecture has been checked over the range $1 \leq n \leq 2^{12} = 4096$.

Finally we must verify inductive hypothesis (3) for $k = 16$. This requires verifying the wild numbers conjecture for $1 \leq m \leq \frac{2^{16} - 1}{189} = \frac{65535}{189} < 400$. It suffices to do this for all primes below 400, except $p = 3$. Representations in the generators of $W$ for all such primes below 50, are given in [3]. (Table 3 gives representations for some of these primes.) For primes $50 \leq p \leq 400$, one can check the criterion by computer using the method of Lemma 3.2, finding by computer search a $q$-smooth number in the appropriate arithmetic progression, for each prime $q$ in the interval,
and using the truth of the $3x + 1$ conjecture for $1 < x < 10^5$. In fact, this $q$-smooth calculation can be carried out by computer for every $q$ with $11 < q < 400$, and only the certificates for $p = 5, p = 7, p = 11$ in Table 3 are needed to begin the induction. As an example, for $q = 13$ we have $a = 2$ and $r = \frac{2aq - 1}{3} = 17$, and the arithmetic progression $78k + 17$ contains $875 = 5^3 \cdot 7$. □

5. Concluding Remarks

The proofs in this paper are computer-intensive. Computer experimentation played an important role in the discovery of the patterns underlying the induction. This included the efficacy of using multipliers to eliminate congruence classes $(\text{mod } 2^k)$ in §2, and in uncovering the existence of the “intractable” residue class $-1 \pmod{2^k}$. If one had studied the problem without using the computer, the “intractable” case $-1 \pmod{2^k}$ could have been uncovered first, and this might have discouraged further investigation of this proof approach. It was also important to have the evidence detailed in [3], which provided a strong element of confidence in the truth of the weak $3x + 1$ conjecture and wild numbers conjecture.

Extensive computations were needed to find the data in the tables. Once found, this data in the tables provides “succinct certificates” for checking correctness of the congruence class properties, which can be verified by hand. Similarly the induction step is in principle checkable by hand.

The proof methods developed in this paper should apply more generally in determining the integers in various multiplicative semigroups of rationals having a similar nature.

Acknowledgments. The authors thank Allan Wilks for helpful computations concerning the wild semigroup in Lemma 3.1. They thank the reviewer for many useful comments, including a suggested revision of the proof of Lemma 3.2 incorporated in this version. The second author did most of his work on this paper while employed at AT&T Labs.
