Drucker, Thomas Münzel, Andreas Daiber, Sebastian Steven

OBJECTIVE: Cardiovascular outcome trials demonstrated that GLP-1 (glucagon-like peptide-1) analogs including liraglutide reduce the risk of cardiovascular events in type 2 diabetes mellitus. Whether GLP-1 analogs reduce the risk for atherosclerosis independent of glycemic control is challenging to elucidate as the GLP-1R (GLP-1 receptor) is expressed on different cell types, including endothelial and immune cells.

APPROACH AND RESULTS: Here, we reveal the cardio- and vasoprotective mechanism of the GLP-1 analog liraglutide at the cellular level in a murine, nondiabetic model of arterial hypertension. Wild-type (C57BL/6J), global (Glp1r−/−), as well as endothelial (Glp1r flox/flox Cdh5 cre) and myeloid cell–specific knockout mice (Glp1r flox/flox LysM cre) of the GLP-1R were studied, and arterial hypertension was induced by angiotensin II. Liraglutide treatment normalized blood pressure, cardiac hypertrophy, vascular fibrosis, endothelial dysfunction, oxidative stress, and vascular inflammation in a GLP-1R–dependent manner. Mechanistically, liraglutide reduced leukocyte rolling on the endothelium and infiltration of myeloid Ly6G− Ly6C+ and Ly6G+ Ly6C+ cells into the vascular wall. As a consequence, liraglutide prevented vascular oxidative stress, reduced S-glutathionylation as a marker of eNOS (endothelial NO synthase) uncoupling, and increased NO bioavailability. Importantly, all of these beneficial cardiovascular effects of liraglutide persisted in myeloid cell GLP-1R-deficient (Glp1r flox/flox*LysM cre) mice but were abolished in global (Glp1r−/−) and endothelial cell–specific (Glp1r flox/flox*Cdh5 cre) GLP-1R knockout mice.

CONCLUSIONS: GLP-1R activation attenuates cardiovascular complications of arterial hypertension by reduction of vascular inflammation through selective actions requiring the endothelial but not the myeloid cell GLP-1R.

VISUAL OVERVIEW: An online visual overview is available for this article.

Key Words: angiotensin II, glucagon-like peptide-1 receptor, hypertension, inflammation, liraglutide, oxidative stress

Arterial hypertension is one of the leading risk factors for atherosclerosis, which culminates in thromboembolic events such as myocardial infarction or stroke and thereby represents a leading cause of global mortality and morbidity with severe disability. Basic research and clinical trials provide substantial evidence for a key role of inflammation in arterial hypertension. In experimental studies, depletion of inflammatory cells in ATII (angiotensin II)-infused mice prevented increased blood pressure and endothelial dysfunction. Furthermore, the CANTOS trial (Canakinumab Antiinflammatory Thrombosis Outcome Study) revealed that...

Highlights

• In the present study, we reveal in a mouse model of arterial hypertension:
  • that GLP-1 (glucagon-like peptide-1) analogs reduce blood pressure and protect endothelial function independent of glucose control;
  • that GLP-1 analogs avoid uncoupling of eNOS (endothelial NO synthase) by reduction of vascular inflammation and oxidative stress;
  • that these protective effects by GLP-1 analogs require the endothelial but not myeloid cell GLP-1 receptor.

the mechanisms are not fully understood, reduction of inflammation has been suggested to play an important role for cardiovascular protection by GLP-1 analogs. Multiple experimental studies have shown that native GLP-1 and pharmacological GLP-1R agonists reduce cardiac and vascular inflammation (for review, see Drucker et al11). Our group demonstrated that the GLP-1 analog liraglutide improves survival in lipopolysaccharide-induced endotoxemia by improving vascular function and reducing systemic and vascular inflammation12 and that these protective effects are lost in global Glp1r−/− mice with sepsis.13 In cell culture experiments, Krasner et al14 showed that liraglutide lowers the induction of VCAM-1 (vascular cell adhesion molecule-1) and E-cadherin by lipopolysaccharide and reduces adhesion of THP-1 (Tohoku hospital pediatrics-1) monocytes to human aortic endothelial cells. Furthermore, animal studies revealed that GLP-1R agonists, including native GLP-1, exendin-4, and liraglutide, attenuate the development of atherosclerosis in murine models.11 GLP-1R agonists are known to reduce white blood cell infiltration and adhesion to the vascular wall in mouse models of atherosclerosis and cardiac dysfunction.15–17 However, the precise mechanism(s) mediating the cardiovascular protective effects of GLP-1 remains poorly understood, and their elucidation is complicated by the fact that the canonical GLP-1R is expressed on several cell types in the vasculature, heart, and on immune cells.15,16,19 Additionally, analysis of GLP-1R expression is complicated by poor specificity and sensitivity of many antibodies (for review see Pujadas et al20). Previous studies reported an essential role of myeloid cells4 and endothelial activation together with eNOS (endothelial NO synthase) dysfunction for the pathogenesis of hypertension.21 To pursue the underlying mechanisms, we have now studied genetic mouse models inactivating the Glp1r in myeloid or endothelial cell lineages.

Here, we show that liraglutide confers antioxidant and anti-inflammatory effects through mechanisms requiring the endothelial GLP-1R. These findings may have relevance for ongoing efforts directed at understanding anti-inflammatory treatment of cardiovascular disease with the monoclonal antibody canakinumab, targeting IL (interleukin)-1β, reduces major adverse cardiovascular events by 15% compared with placebo in patients with atherosclerotic cardiovascular disease.3 Thus, anti-inflammatory therapy has the potential to significantly lower rates of recurrent cardiovascular events.

GLP-1 (glucagon-like peptide-1) is a peptide hormone with known anti-inflammatory properties that was first discovered as a regulator of insulin release from β-cells in the pancreas, and synthetic analogs of GLP-1 are used for the treatment of type 2 diabetes mellitus. Clinical trials of GLP-1 analogs were designed to test the cardiovascular safety in patients with diabetes mellitus. Unexpectedly, long-acting GLP-1R (GLP-1 receptor) agonists reduced the risk of cardiovascular events in subjects with type 2 diabetes mellitus, with similar risk reduction (eg, LEADER trial [Liraglutide Effect and Action in Diabetes Evaluation of Cardiovascular Outcome Results] hazard ratio, 0.87 [95% CI 0.78–0.97] P = 0.01) as observed for IL-1β blockade by canakinumab (hazard ratio, 0.85 [95% CI 0.74–0.98] P = 0.21).3,6,7 Other clinical trials investigating the effects of GLP-1 on cardiovascular disease demonstrated cardiovascular protective effects after myocardial infarction,4 reduction of blood pressure,9 and an improvement of endothelial dysfunction.10 Although
clinical observations linking GLP-1R agonists to reduction of major adverse cardiovascular events.

**MATERIALS AND METHODS**

The authors declare that all supporting data are available within the article and its online-only Data Supplement.

**Animals and In Vivo Treatment**

All animals were treated in accordance with the Guide for the Care and Use of Laboratory Animals as adopted by the US National Institutes of Health and approval was granted by the Ethics Committee of the University Hospital Mainz and the Landesuntersuchungsamt Rheinland-Pfalz (Koblenz, Germany; permit number: 23 177-07/G 17-1-050). The studies were performed in male C57BL/6J, global Glp1r<sup>−/−</sup>,<sup>22</sup> and endothelial (Glp1r<sup>flox/flox</sup>×Cdh5<sup>cre</sup>, Glp1r<sup>ec<sup>−/−</sup></sup>) as well as myelomonocytic (Glp1r<sup>flox/flox</sup>×LysM<sup>cre</sup>, Glp1r<sup>my</sup><sup>−/−</sup>) cell–specific GLP-1R knockout mice (8–12 weeks old). According to Payne et al.,<sup>23</sup> a nonspecific cre recombinase activity has been noted in hematopoietic cells for the Cdh5<sup>cre</sup> alleles. In the recent study, unintended deletion of the GLP-1R in Glp1r<sup>−/−</sup> mice other than endothelial cells was excluded by evaluation of Glp1r mRNA in mouse white blood cells (Figure IIIF in the online-only Data Supplement). Animals were housed under a 12-hour light/dark cycle in the institutional animal facility with free access to standard diet and water. Effects of sexual hormones on vascular function are known. To exclude the latter effects in the present study, experiments were performed in male mice only. For detailed description, see online-only Data Supplement.

**Detection of Oxidative Stress**

Oxidative stress was detected in whole blood, heart, and vascular tissue.<sup>26,27</sup> For detailed description, see online-only Data Supplement.

**Noninvasive Blood Pressure Recordings**

Noninvasive blood pressure recording was performed by tail-cuff to determine systolic blood pressure with a Coda Monitor System (Kent Scientific), which has been validated against telemetry monitoring.<sup>28</sup> For detailed description, see online-only Data Supplement.

**S-Glutathionylation of eNOS and Western Blotting**

eNOS was immunoprecipitated, and the precipitate was subsequently immunoblotted for S-glutathionylation.<sup>29</sup> For detailed description, see online-only Data Supplement.

**Electron Paramagnetic Resonance Spectroscopy**

Electron paramagnetic resonance spectroscopy was used to assess aortic NO synthesis/bioavailability using colloid Fe(II)-diethyldithiocarbamate (Fe(DETC)) as spin trap.<sup>30</sup> For detailed description, see online-only Data Supplement.

**Determination of Nitrate and Nitrite**

Nitrate and nitrite were measured by ENO-20 NOx analyzer (Eicom Corporation, Tokyo, Japan), based on the liquid chromatography method with postcolumn derivatization with Griess reagent.<sup>31</sup> For detailed description, see online-only Data Supplement.

**Intravital Fluorescence Microscopy**

A real-time imaging software (NIS Elements, Nikon) was used for image acquisition and analysis. Cell recruitment was quantified in 6 fields of view (100μm×150μm) per femoral vein.<sup>32</sup> For detailed description, see online-only Data Supplement.

**Isometric Tension Recordings**

For vascular reactivity studies, 4 mm thoracic aortic rings free of perivascular fat were mounted on force transducers in organ bath chambers and preconstricted with prostaglandin F<sub>2α</sub> (2 μM) to reach ≈80% of the maximal tone induced by KCl bolus. Concentration-relaxation curves were recorded in response to the endothelium-dependent vasodilator acetylcholine (1 nM–3.3 μM).<sup>33</sup>

**Reverse Transcription Polymerase Chain Reaction**

The acid guanidinium thiocyanate-phenol-chloroform extraction method was used for RNA isolation.<sup>24</sup> For detailed description see online-only Data Supplement.

**Statistics**

Data are expressed as means±SEM. Statistical calculations were performed with GraphPad Prism 7 (GraphPad Software, Inc). The unpaired Student t test was used after testing for normality and equal variance (Shapiro-Wilk test) to compare 2 groups. One-way ANOVA and Bonferroni or Tukey post hoc test were used to compare multiple groups if the data followed a normal distribution, otherwise nonparametric Kruskal-Wallis and Dunn post hoc tests were used. Two-way ANOVA (with Bonferroni correction for comparison of multiple means) was used for comparisons of vasodilator potency and efficacy in response to the endothelium-dependent vasodilator acetylcholine. A limitation of the study is a reduced sample size in some experiments in which only 3 to 4 animals were used. P<0.05 were considered statistically significant and marked by asterisks (*P<0.05; **P<0.01; ***P<0.001; ****P<0.0001).

**RESULTS**

**Liraglutide Improves Blood Pressure and Cardiac Hypertrophy in ATII-Induced Arterial Hypertension Independent of Glucose/Insulin Modulation**

Chronic ATII infusion in C57BL/6J mice increased systolic blood pressure associated with development of cardiac hypertrophy. These effects of ATII infusion were completely normalized by administration of the GLP-1 analog liraglutide (Figure 1A through 1C). Liraglutide led to a significant reduction in body weight after 7 days of treatment, whereas ATII infusion alone showed no significant effect.
on body weight (Figure 1D). Neither ATII infusion nor liraglutide treatment had any significant effect on glucose homeostasis, as assessed by unaltered blood glucose and plasma insulin levels after an oral glucose tolerance test (Figure 1E and 1F, Figure 1H and II in the online-only Data Supplement). Expression of \textit{Glp1r} mRNA in aorta was not affected by ATII but was significantly elevated in response to liraglutide treatment (Figure IA in the online-only Data Supplement). Thus, liraglutide reduces blood pressure without impacting glucose homeostasis in nondiabetic mice with ATII-induced arterial hypertension, leading to amelioration of cardiac hypertrophy.

**Liraglutide Reduces Cardiac and Whole Blood Oxidative Stress by Suppression of Inflammation and NADPH Oxidase Activity in ATII-Induced Arterial Hypertension**

Hypertensive mice had significantly higher levels of reactive oxygen species in whole blood and cardiac tissue, accompanied by elevated levels of 3-NT (3-nitrotyrosine) positive proteins in the heart, all of which were reduced by liraglutide treatment (Figure 2A through 2C). In addition, liraglutide significantly decreased ATII-induced oxidative stress in cardiac tissue caused by an increase of Nox (NADPH oxidase) activity (Figure 2D), reduced elevated levels of ADMA (asymmetrical dimethylarginine) known to promote dysregulation of the eNOS (Figure 2E), and attenuated F4/80 expression in cardiac tissue as an indicator for infiltration of immune cells into the heart (Figure 2F). Thus, liraglutide reduces cardiac oxidative stress in ATII-induced hypertensive heart disease.

**Liraglutide Improves ATII-Induced Endothelial Dysfunction and Vascular Fibrosis by Reduction of Vascular Oxidative Stress and Recoupling of eNOS**

ATII-infused mice exhibited impaired endothelial function, and Sirius red staining revealed significant vascular fibrosis,
a contributor to vascular stiffness. Treatment with liraglutide reduced the development of adverse vascular effects in ATII-treated mice (Figure 3A and 3D), whereas liraglutide treatment had no effect on vascular function in nonhypertensive animals (Figure IB in the online-only Data Supplement). ATII-infused mice showed eNOS uncoupling as revealed by a marked increase in S-glutathionylation of the enzyme and further supported by L-NAME (L-NG-nitroarginine methyl ester) inhibitable endothelial dihydroethidium staining (Figure 3B and 3C), consistent with the extent of endothelial dysfunction (Figure 3A) and impaired NO bioavailability (Figure 3E). These adverse effects of ATII infusion were all normalized by liraglutide treatment (Figure 3A through 3E). Plasma levels of nitrate (NO₃⁻) were increased in hypertensive mice, indicative of pronounced oxidative break-down of NO and/or iNOS (inducible NO synthase) activity, which was further supported by increased mRNA expression of Nox2 and iNOS (or Nos2) in the aorta of ATII-infused mice (Figure 3F through 3H). Liraglutide administration significantly reduced the inflammatory burden reflected by lowered Nox2 and Nos2 mRNA levels in aorta and attenuated nitrate plasma levels (Figure 3F through 3H). Thus, the GLP-1 analog liraglutide displays antioxidant and anti-inflammatory properties that help to prevent eNOS uncoupling, resulting in higher NO bioavailability and vascular protection in arterial hypertension.

Liraglutide Ameliorates ATII-Induced Inflammation of the Vasculature by Prevention of Ly6G⁻Ly6C⁻ and Ly6G⁺ Ly6C⁺ Cell Infiltration to the Vessel Wall

Intravital microscopy visualized a trend of increased rolling of leukocytes at the inner vascular wall in ATII-infused mice. Liraglutide administration significantly suppressed
rolling of leukocytes in arterial hypertension (Figure 4A). Representative videos of intravital microscopy are available in the online-only Data Supplement. In support of an enhanced inflammatory phenotype in the aorta of hypertensive mice, nuclear factor κB (NF-κB; Figure 4B), tumor necrosis factor alpha (Tnfa) mRNA, and IL-1β protein expression, as well as transforming growth factor beta (Tgfb) and interferon gamma (Ifng) mRNA expression (Figure IC through IF in the online-only Data Supplement) were markedly upregulated upon ATII infusion. Furthermore, mRNA transcripts corresponding to Vcam1, intercellular adhesion molecule-1 (Icam1) and Selp, encoding adhesion molecules (VCAM-1, ICAM-1 and P-selectin) and known downstream targets of NF-κB, were strongly upregulated in the aortas of ATII-infused mice (Figure 4C through 4E). This proinflammatory cascade responsible for leukocyte adhesion and migration was mitigated by liraglutide treatment (Figure 4B through 4E, Figure IC through IF in the online-only Data Supplement). Immunohistochemical staining of blood vessels

Figure 3. Liraglutide (Lira) improves ATII (angiotensin II)-induced endothelial dysfunction and vascular fibrosis by recoupling of eNOS (endothelial NO synthase) and reduction of vascular oxidative stress.

A, In wild-type mice (C57BL/6J), vascular function was evaluated by endothelium (E)-dependent (acetylcholine [ACh]) relaxation of aortic rings (isometric tension studies). Two-way ANOVA and Bonferroni multiple comparison test; N=16–28 animals per group. B, S-glutathionylation of eNOS as a readout for uncoupling of the enzyme was measured by using a specific glutathione antibody (GSH) after immunoprecipitation of eNOS. Representative Western blot images are shown below the densitometric analysis. C, The specific NOS-inhibitor L-NAME (L-N^G-nitroarginine methyl ester) was used in aortic cryosections stained with dihydroethidium (DHE) to detect reactive oxygen species (ROS) and to uncover eNOS uncoupling. Representative photomicrographs are shown below the densitometric analysis. Green, laminae (autofluorescence); red fluorescence, superoxide formation. D, Representative (out of 3–4) Sirius red stainings of aorta are shown to demonstrate vascular fibrosis. E, Electron paramagnetic resonance spectroscopy revealed NO levels in aorta. Representative electron paramagnetic resonance spectroscopy (EPR) spectra showing the resulting iron-nitrosyl triplet signal are shown besides the quantification bar graph. F, High-performance liquid chromatography (HPLC) was used to detect nitrate (NO_3^-) in plasma. Representative chromatograms are shown besides the quantification bar graph. G and H, NADPH oxidase 2 (Nox2) and inducible NO synthase (iNOS/Nos2) mRNA expression was measured by quantitative reverse transcription polymerase chain reaction in aortic tissue. One-way ANOVA and Bonferroni multiple comparison test; N=4 (B), 8 without and 3 with L-NAME (C), 3–6 (E), 4 (F), and 4–6 (G and H). Data are means±SEM. *P<0.05; **P<0.01; ***P<0.001; ****P<0.0001.
revealed high expression of Ly6B.2 as an indicator for vascular inflammation in ATII-infused mice, which was normalized by liraglutide treatment (Figure 4F). Using flow cytometry, we identified specific subsets of immune cells, namely Ly6G-Ly6C+ inflammatory monocytes and Ly6G+Ly6C+ neutrophils, that infiltrated into the vascular wall of hypertensive animals, findings attenuated by liraglutide administration (Figures 4G and 4H). Thus, liraglutide ameliorates ATII-induced rolling and infiltration of leukocytes by downregulation of central proinflammatory mediators (NF-κb, TNF-α, and IL-1β) with concomitant reduced expression of adhesion molecules (VCAM-1, ICAM-1, and P-selectin).

**Canonical GLP-1R Expressed on Endothelial Cells, Not on Myeloid Cells, Is Essential for Cardiovascular Protection by Liraglutide.**

Global *Glp1r*−/− mice exhibited impaired endothelial function compared to C57BL/6J mice, which was further deteriorated by ATII infusion; treatment with liraglutide did
not improve acetylcholine-dependent vasodilation in the absence of a functional canonical GLP-1R (Figure 5A). Similarly, liraglutide did not reduce vascular oxidative stress in ATII-infused Glp1r–/– mice (Figure 5B). Furthermore, liraglutide failed to normalize and even deteriorated levels of aortic Nox2, Nos2, and Tnfa mRNA as well as cardiac Nox2 activity in ATII-infused Glp1r–/– mice (Figures 5C through 5F). Collectively, these findings suggest that the cardiovascular protection seen in C57BL/6J mice is mediated via canonical GLP-1R activation.

To better define the cellular target of vascular-protective liraglutide signaling through GLP-1R, we generated endothelial cell–specific (Glp1r ec–/–) and myeloid cell–specific (Glp1r my–/–) GLP-1R knock-out mice.
Figure 6. The canonical GLP-1 (glucagon-like peptide-1) receptor expressed on myeloid cells (LysM⁺) is not responsible for cardiovascular protection by liraglutide (Lira).

A, In myeloid cell (LysM⁺)-specific GLP-1 receptor knockout mice (Glp1rflox/floxxLysMcre, Glp1r my⁻/⁻), mRNA expression of the Glp1r was measured in bone marrow–derived macrophages (BMDM) and expression levels are shown in relation to the background strain (LysM⁺ mice). Student t test; N=3 animals per group. B, Vascular function was evaluated by endothelium-dependent (acetylcholine [ACh]) relaxation of aortic rings (isometric tension studies). Two-way ANOVA and Bonferroni multiple comparison test; N=16–22 animals per group. C, Representative (out of 3–4) Sirius red staining of aortic sections to assess vascular fibrosis. D and E, Flow cytometry of aortic cell suspensions identified Ly6G⁻Ly6C⁺ inflammatory monocytes and Ly6G⁺Ly6C⁺ neutrophils inside the vascular wall. Representative original plots of Ly6G⁻Ly6C⁺ and Ly6G⁺Ly6C⁺ cells are shown beside the quantification bar graph (for gating strategy, see Figure IV in the online-only Data Supplement). One-way ANOVA and Bonferroni multiple comparison test; N=5–9 animals per group. Data are means±SEM. ATII indicates angiotensin II; FITC, fluorescein isothiocyanate; and n.d., not detectable. *P<0.05; **P<0.01; ***P<0.001; ****P<0.0001.
Figure 7. The canonical GLP-1 (glucagon-like peptide-1) receptor expressed on endothelial cells is essential for cardiovascular protection by liraglutide (Lira).

A, In endothelial cell–specific GLP-1 receptor knockout mice (Glp1r<sup>flox</sup>/<sup>flox</sup>xCdh5<sup>cre</sup>, Glp1r ec<sup>−/−</sup>), mRNA expression of the Glp1r was measured in isolated mouse lung endothelial cells (MLECs) and expression levels are shown in relation to the background strain (Cdh5<sup>cre</sup> mice). Student t test; N=4 animals per group. B, Vascular function was evaluated by endothelium-dependent (acetylcholine [ACh]) relaxation of aortic rings (isometric tension studies). Two-way ANOVA and Bonferroni multiple comparison test; N=20–30 animals per group. C, Systolic blood pressure in mice was determined by noninvasive blood pressure recording on day 6 of ATII (angiotensin II) infusion. D, Representative (out of 3–4) Sirius red staining of aortas reveal vascular fibrosis. E, NADPH oxidase 2 (Nox2) mRNA expression was measured by quantitative reverse transcription polymerase chain reaction in aortic tissue. Helmstädt et al Cardiovascular Protection by GLP-1 Analog

GLP1r mRNA in bone marrow–derived macrophages of myeloid-specific knockout mice (GLP1r my−/−) was not detectable compared to the background strain (LysMcre−/− mice; Figure 6A). Moreover, ATII infusion and liraglutide treatment did not alter nonfasting blood glucose in GLP1r ec−/− and GLP1r my−/− mice (Figures IIA and IIIA in the online-only Data Supplement). However, liraglutide reduced body weight in both mouse strains (Figures IIB and IIIIB in the online-only Data Supplement).

Given the demonstrated reduction of leukocyte infiltration by liraglutide treatment in the wild-type mice, we first analyzed the response to ATII infusion in GLP1r my−/− mice. Unlike findings in the global GLP1r−/−, ATII-induced vascular dysfunction was evident in GLP1r my−/− mice (Figures IIIC, IID, and IIID in the online-only Data Supplement), vascular fibrosis (Figure 6C), and myeloid cell infiltration of the vessel wall induced by ATII infusion was markedly reduced by liraglutide treatment (Figure 6B). In addition, cardiac hypertrophy (Figure IIC in the online-only Data Supplement), vascular fibrosis (Figure 6C), and myeloid cell infiltration of the vessel wall induced by ATII infusion was markedly reduced by liraglutide treatment (Figure 6B). Hence, GLP1R expression in myeloid cells is not required for the cardiovascular protective effect of liraglutide.

Mouse lung endothelial cells of GLP1r ec−/− (GLP1rflox/flox xCd5cre−/−) mouse contained about 90% less GLP1r mRNA compared with the background strain (Cd5cre−/− mice), and a knockdown of GLP1r in white blood cells was ruled out (Figure 7A, Figure IIIF in the online-only Data Supplement). In contrast to GLP1r my−/− mice, liraglutide failed to improve endothelial function (Figure 7B) or reduce blood pressure (Figure 7C) in hypertensive GLP1r ec−/− mice. Vascular fibrosis (Figure 7D) and cardiac hypertrophy (Figure IIIC in the online-only Data Supplement) was aggravated by ATII infusion and not significantly improved by liraglutide treatment in GLP1r ec−/− mice, in contrast to findings in GLP1r my−/− mice. Furthermore, liraglutide failed to prevent upregulation of Nox2, Vcam1, and Tnfα mRNA (Figure 7E and Figure IIID and IIIE in the online-only Data Supplement) as well as higher nitrate levels indicative of oxidative NO break-down and iNOS activity (Figure 7F) in hypertensive GLP1r ec−/− mice. Associated with these signs of persistent endothelial dysfunction, the infiltration of Ly6G+Ly6C+ inflammatory monocytes and Ly6G+Ly6C+ neutrophils was significantly reduced by liraglutide treatment of ATII-infused GLP1r ec−/− mice (Figure 7G and 7H). Thus, the cardiovascular protection of liraglutide in mice with ATII-induced vascular dysfunction is predominantly mediated via the endothelial GLP1R.

DISCUSSION

Here, we show that the GLP1R analog liraglutide prevents the adverse cardiovascular effects of ATII-induced arterial hypertension. Liraglutide exerts its cardiovascular protective actions through the GLP1R and normalizes vascular inflammation, oxidative stress, endothelial function, blood pressure, and cardiac hypertrophy in this animal model of arterial hypertension. Mechanistically, GLP1R activation by liraglutide ameliorates wall injury by Ly6G+Ly6C+ inflammatory monocytes and Ly6G+Ly6C+ neutrophils, which in turn lowers oxidative stress and prevents uncoupling of eNOS in hypertensive mice. NO bioavailability is thereby maintained, endothelium-mediated vasorelaxation is preserved, and vascular remodeling and fibrosis are prevented. Consistent with the known actions of GLP1R, we found no effects of liraglutide on glycemia or insulin levels, supporting a glucose-independent mechanism. We identify that the canonical GLP1R expressed on endothelial cells, but not on myeloid cells, is required for the cardiovascular protection by the GLP1R analog liraglutide.

GLP1R agonists lower blood pressure in preclinical studies and humans. One potential mechanism was proposed by Kim et al. who showed that GLP1R activation by liraglutide promotes the secretion of ANP (atrial natriuretic peptide) with a subsequent increase of cGMP-mediated vasorelaxation and urinary sodium secretion leading to reduction of blood pressure in ATII-infused mice. The effect was dependent on the canonical GLP1R and absent in global GLP1R knockout mice. With the present studies, we found a comparable blood pressure reduction by liraglutide, which resulted in a reduction of cardiac hypertrophy and reduced heart/body weight ratio (both parameters indicative of hypertensive heart disease), which were associated with a reduction of body weight but independent of glucose-lowering. Liraglutide also reduced systemic and cardiac oxidative stress and inflammation. Studies using a cardiomyocyte-specific GLP1R knockout strain (GLP1rflox/flox κb−/−) found no relevant role for the GLP1R expressed on cardiomyocytes in ischemic cardiomyopathy, which excludes that direct liraglutide effects on cardiomyocytes are responsible for the cardioprotective effects. Thus, improvements of cardiac hypertrophy, cardiac oxidative stress, and inflammation likely result from blood pressure lowering effects and prevention of infiltration of immune cells by liraglutide. The blood pressure reduction by liraglutide was consistent with previous data but clearly of greater magnitude compared with human studies in which a blood pressure reduction of 2 to 4 mm Hg is reported. The latter represents a limitation of the present study with respect to translation of our animal data and their clinical relevance.

Vascular inflammation is a crucial component in the development of arterial hypertension with sequential steps of inflammatory cell infiltration into the vascular wall, resulting in high levels of vascular oxidative stress and eNOS uncoupling and finally atherosclerosis. GLP1R activation on endothelial cells prevented these effects and improved vascular relaxation and NO bioavailability in ATII-infused mice. Mechanistically, liraglutide suppressed an inflammatory cascade involving NF-κb and downregulated mRNA encoding vascular adhesion molecules VCAM-1, ICAM-1, and P-selectin in the arteries, which explains the observed reduction in leukocyte rolling and vessel wall infiltration.
In a selective ablation model of lysozyme M-positive (LysM+) myelomonocytic cells, it has been shown that infiltrating proinflammatory monocytes and macrophages cause vascular oxidative stress and mediate ATII-induced vascular dysfunction. Consistent with these findings, reduced leukocyte infiltration in liraglutide-treated animals was associated with attenuated vascular reactive oxygen species production, restoration of the function of eNOS and suppression of Nos2/Nox2 mRNA expression. Under conditions of high oxidative stress, eNOS uncouples and converts into a source of reactive oxygen species, which is specifically detectable by reduced aortic NO bioavailability, eNOS S-glutathionylation, and eNOS-dependent reactive oxygen species formation by using the selective NOS-inhibitor L-NAME in dihydroethidium cryosections. In contrast, increased iNOS activity was demonstrated for the ATII hypertension model. Liraglutide treatment interrupted this detrimental cascade in hypertensive mice by prevention of leukocyte influx and vascular inflammation.

Our data are in agreement with cell culture experiments of Hattori et al demonstrating that liraglutide causes a dose-dependent increase of NO release in human umbilical vein endothelial cells via eNOS activation and downregulation of NFKB1, TNFA, VCAM1, and ICAM1 mRNA expression. Similar observations have been made in ApoE−/− mice treated with GLP-1 analog for 28 days, where extendin-4 reduced numbers of Mac2+ cells adhering to the endothelium and decreased levels of Vcam1 and icam1 mRNA. Similar evidence for a mechanistic involvement of the GLP-1R was demonstrated using the GLP-1R antagonist extendin (9-39) to diminish liraglutide’s protective effect in atherosclerosis-prone ApoE−/− mice.

Anti-inflammatory effects of GLP-1 analogs are well established. Nevertheless, it still remains unclear whether GLP-1R agonists modify immune cell function through direct effects on immune cells or indirect mechanisms (eg, suppression of endothelial cell activation) and whether these effects require the canonical GLP-1R. Immunoreactive GLP-1R protein and Glp1r mRNA transcripts have been detected in murine monocytes and macrophages, but due to low sensitivity and specificity of GLP-1R antibodies, the precise cellular and tissue expression of the immune GLP-1R remains uncertain. Endothelial cells also express the canonical GLP-1R; however, the importance of the endothelial GLP-1R for the cardiovascular protection by GLP-1R agonists has been unexplored. Nevertheless, multiple studies have demonstrated effects of GLP-1 analogs on endothelial cells and vascular function ex vivo and in vivo in mice and humans (for review see Drucker et al). GLP-1R agonists are thought to exert cardiovascular protection dependent on the known GLP-1R. However, GLP-1(9-36)amide, generated by DPP-4-mediated cleavage of native GLP-1, exerts cardioprotective actions in the ischemic mouse heart. Moreover, GLP-1(9-36) also exerts direct vasodilatory actions on murine blood vessels and induces vasodilation in mesenteric vessels. These actions persisted in blood vessels of Glp1r−/− mice. Hence, we cannot fully exclude a potential contribution of GLP-1R independent effects of liraglutide and its metabolites, which represents a limitation of our present study.

Here, we demonstrated that the canonical GLP-1R expressed on endothelial cells, but not on myeloid cells, is required to improve endothelial dysfunction by reduction of vascular inflammation and oxidative stress in a murine model of arterial hypertension. Glp1r−/− mice exhibit endothelial dysfunction, which was only modestly exacerbated by ATII, suggesting a role of the endogenous GLP-1R system in vascular function. The latter hypothesis is supported by a recent report by He et al who demonstrated that increased endogenous GLP-1 bioavailability protects against atherosclerosis. Importantly, liraglutide failed to normalize endothelial function, vascular oxidative stress, cardiac NOx activity, and mRNA expression of proinflammatory genes (Nos2, Nos2, Tnfa) in hypertensive Glp1r−/− mice, clearly highlighting the essential role of GLP-1R signaling for cardiovascular protection by GLP-1 analogs. However, blood pressure and cardiac hypertrophy trended lower in liraglutide-treated Glp1r ec−/− mice, consistent with previous findings in mice invoking a role for ANP in the blood pressure reduction produced by GLP-1R agonists.

In conclusion, clinical trials revealed that the GLP-1 analog liraglutide and multiple structurally distinct GLP-1R agonists improve cardiovascular outcomes through incompletely understood mechanisms, in which atherosclerosis might play an essential role. The present study provides evidence that liraglutide prevents endothelial dysfunction and lowers blood pressure in normoglycemic mice with experimental arterial hypertension, a major risk factor for atherosclerosis and subsequent cardiovascular disease. This was in concert with a reduction of vascular inflammation, and subsequent normalization of vascular oxidative stress. The GLP-1R expressed on endothelial, but not on myeloid cells, plays an indispensable role in the cardiovascular protection induced by liraglutide in mice with ATII-induced experimental hypertension. Given the major role of renin-angiotensin-aldosterone system activation for cardiovascular and renal complications observed in patients with diabetes mellitus, our present data obtained in a model of ATII-triggered hypertension may contribute to a better understanding of the cardio-protective effects of liraglutide reported in clinical trials.

Acknowledgments
We are indebted to Jessica Rudolph, Jörg Schreiner, Bettina Mros, Nicole Glas, and Angelica Karpi for expert technical assistance. This article contains results that are part of the doctoral thesis of Johanna Helmstädter. We are grateful to Randee Seeley, University of Michigan, providing the Glp1rflox/flox mouse and to Christoph Reinhardt (Platform Intravital Microscopy of the Center for Thrombosis and Hemostasis, Mainz, Germany) for providing the intravital microscopy platform.

Sources of Funding
This study was supported by a grant of the German Research Foundation (DFG STE2528/2-1) to S. Steven, who holds a Vischow-Fellowship from the Center for Thrombosis and Hemostasis (Mainz, Germany) funded by the Federal Ministry of Education and Research (BMBF 01EO1003). K. Frenis and S. Kalinovic hold PhD stipends from the TransMed PhD Program at the University Medical Center Mainz, and their positions are funded by a vascular biology research grant within the collaborative research group "Novel and neglected cardiovascular risk factors" from the Boehringer Ingelheim Foundation. P. Wenzel is supported DFG (WE4361/7-1) and BMBF (01EO1003). D.J. Drucker is supported by a CiHR (Canadian Institutes of Health Research) Grant 154321, a BBDC (Banting & Best Diabetes Centre)-Novo Nordisk Chair in Incretin Biology and operating grant support from Novo Nordisk, Inc. S. Chlopicki is supported by FNP (Foundation for Polish Science) Team Tech–Core Facility program. We thank the Mainz Heart Foundation for continuous support. T. Münzer, P. Wenzel, and W. Ruf are Principal Investigator of the DZHK (German Center for Cardiovascular Research), Partner Site Rhine-Main, Mainz, Germany.
