Limit theorem for reflected random walks

Hoang-Long Ngo∗ Marc Peigné †

October 4, 2019

Abstract

Let \( \xi_n, n \in \mathbb{N} \) be a sequence of i.i.d. random variables with values in \( \mathbb{Z} \). The associated random walk on \( \mathbb{Z} \) is \( S(n) = \xi_1 + \cdots + \xi_{n+1} \) and the corresponding “reflected walk” on \( \mathbb{N}_0 \) is the Markov chain \( X(n), n \in \mathbb{N} \), given by \( X(0) = x \in \mathbb{N}_0 \) and \( X(n+1) = |X(n) + \xi_{n+1}| \) for \( n \geq 0 \). It is well known that the reflected walk \( (X(n))_{n \geq 0} \) is null-recurrent when the \( \xi_n \) are square integrable and centered. In this paper, we prove that the process \( (X(n))_{n \geq 0} \), properly rescaled, converges in distribution towards the reflected Brownian motion on \( \mathbb{R}^+ \), when \( \mathbb{E}[\xi_n^2] < +\infty \), \( \mathbb{E}[(\max(0,-\xi_n)^3] < +\infty \) and the \( \xi_n \) are aperiodic and centered.

Keywords: Invariance principle · Reflected Brownian motion · Renewal function

1 Introduction and notations

Let \((\xi_n)_{n \geq 1}\) be a sequence of \( \mathbb{Z} \)-valued, independent and identically distributed random variables, with common law \( \mu \) defined on a probability space \((\Omega, \mathcal{F}, \mathbb{P})\). We denote \( S = (S(n))_{n \geq 0} \) the classical random walks with steps \( \xi_k \) defined by \( S(0) = 0 \) and \( S(n) = \xi_1 + \cdots + \xi_n \) for any \( n \geq 1 \).

Throughout this paper, we denote \( \mathbb{N}_0 \) the set of non-negative integers and we consider the reflected random walk \((X(n))_{n \geq 0}\) on \( \mathbb{N}_0 \) defined by

\[
X(n+1) = |X(n) + \xi_{n+1}|, \quad \text{for } n \geq 0,
\]

where \( X(0) \) is a \( \mathbb{N}_0 \)-valued random variables. When \( X(0) = x \) \( \mathbb{P} \)-a.s., with \( x \in \mathbb{N}_0 \), the process \((X(n))_{n \geq 0}\) is also denoted by \((X^x(n))_{n \geq 0}\). It evolves as the random walk \( x + S(n) \) as long as it stays non negative. When \( x + S(n) \) enters the set of negative integers, the sign of its value is changed; the same construction thus applies starting from \( |x + S(n)| \), \ldots and so on.

The process \((X^x(n))_{n \geq 0}\) is a Markov chain on \( \mathbb{N}_0 \) starting from \( x \). Several papers describing its stochastic behavior have been published; we refer to [16] where the recurrence of the reflected random walk is studied under some conditions which are nearly to be optimal. The reader may find also several references therein.

Firstly, \((X^x(n))_{n \geq 0}\) has some similarities with the classical random walk on \( \mathbb{R} \); for instance, a strong law of large numbers holds, namely

\[
\lim_{n \to +\infty} \frac{X^x_n}{n} = 0 \quad \mathbb{P}\text{-a.s.}
\]

Theorem 1.1. Let $(\xi_n)_{n \geq 1}$ be a sequence of $\mathbb{Z}$-valued i.i.d. random variables such that

A1. $\mathbb{E}[\xi_n^2] = \sigma^2 < +\infty$ and $\mathbb{E}[\max(0, -\xi_n)^3] < +\infty$;

A2. $\mathbb{E}[\xi_n] = 0$;

A3. The distribution of the $\xi_n$ is strongly aperiodic, i.e. the support of the distribution of $\xi_n$ is not included in the coset of a proper subgroup of $\mathbb{Z}$.

Let $(X_n(t))_{t \geq 0}$ be the continuous time process constructed from the sequence $(X(n))_{n \geq 0}$ by linear interpolation between the values at integer points. Then, as $n \to +\infty$, the sequence of stochastic processes $(X_n(t))_{n \geq 1}$, defined by

$$X_n(t) := \frac{1}{\sigma \sqrt{n}} X(nt), \quad n \geq 1, 0 \leq t \leq 1,$$

weakly converges in the space of continuous functions on $[0, 1]$ to the absolute value $(|B(t)|)_{t \geq 0}$ of the Brownian motion on $\mathbb{R}$.

Let us insist on the fact that $X^x(n)$ coincides with $x + S(n)$ as long as it stays non-negative, but after it may differ drastically. The sequence of successive reflection times of $(X^x(n))_{n \geq 0}$ introduces some strong inhomogeneity on time and makes it necessary to adopt a totally different approach to prove an invariance principle as stated above.

A model which is very similar to $(X^x(n))_{n \geq 0}$ is the queuing process $(W^x(n))_{n \geq 0}$, also called the Lindley process, corresponding to the waiting times in a single server queue. We think to $(W^x(n))_{n \geq 0}$ as an absorbing random walk on $\mathbb{N}_0$; as $W^x(n)$, it evolves as the random walk $x + S(n)$ as long as it stays non-negative and, when it attempts to cross 0 and become negative, the new value is reset to 0 before continuing. We refer to [15] for precise descriptions and variations on this process and follow the same strategy to obtain the invariance principle.

The excursions of $(W^x(n))_{n \geq 0}$ and $(X^x(n))_{n \geq 0}$ between two consecutively times of absorption-reflection coincide with some parts of the trajectory of $(S(n))_{n \geq 0}$, up to a translation; thus, their study is related to the fluctuations of $(S(n))_{n \geq 0}$. Hence, as in [15], we introduce the sequence of strictly descending ladder epochs $(\ell_l)_{l \geq 0}$ of the random walk $(S(n))_{n \geq 0}$ defined inductively by $\ell_0 = 0$ and, for any $l \geq 1$,

$$\ell_{l+1} := \min\{n > \ell_l \mid S(n) < S(\ell_l)\}.$$

When $\mathbb{E}[|\xi_n|] < +\infty$ and $\mathbb{E}[\xi_n] = 0$, the random variables $\ell_1, \ell_2 - \ell_1, \ell_3 - \ell_2, \ldots$ are $\mathbb{P}$-a.s. finite and i.i.d. and the same property holds for the random variables $S(\ell_1), S(\ell_2) - S(\ell_1), S(\ell_3) - S(\ell_2), \ldots$. In other words, the processes $(\ell_l)_{l \geq 0}$ and $(S(\ell_l))_{l \geq 0}$ are random walks on $\mathbb{N}_0$ and $\mathbb{Z}$ with respective distribution $\mathcal{L}(\ell_1)$ and $\mathcal{L}(S(\ell_1))$.

Let us explain briefly the main difference between $(W^x(n))_{n \geq 0}$ and $(X(n))_{n \geq 0}$. At an absorption time, the value of the process $W^x(n)$ is reset to 0 before continuing as a classical random walk for a while: there is a total loss of memory of the past after each absorption. Rather, at a reflection time, the process $X^x(n)$ equals the absolute value of $x + S(n)$. This value is the “new” starting point of
the process, for a while, and has a great influence on the next reflection time; in other words, the process always captures some memory of the past at any time of reflection. This phenomenon has to be taken into account and requires a precise study of the sub-process \((X(r_k))_{k \geq 0}\) of \((X(n))_{n \geq 0}\) corresponding to these successive times \((r_k)_{k \geq 0}\) of reflection; our strategy consists in studying the spectrum of the transition probabilities matrix \(R\) of \((X_n)_{k \geq 0}\), acting on some Banach space \(B = \mathcal{B}_\alpha\) of functions from \(\mathbb{N}_0\) to \(\mathbb{C}\) with growth less than \(x^\alpha\) at infinity, for some \(\alpha > 0\) to be fixed. In particular, in order to apply recent results on renewal sequences \([9]\), we need precise estimates on the tail of distribution of the reflection times; this is the main reason of the restrictive assumption \(\mathbb{E}[\max(0, -\xi_n)^3] < +\infty\) instead of moment of order 2, as we could expect. More precisely, throughout the paper, we need the following properties to be satisfied:

(i) The operator \(R\) acts on \(\mathcal{B}_\alpha\); this holds when \(\mathbb{E}[|S(\ell_1)|^{1+\alpha}] < +\infty\) and yields to the condition \(\mathbb{E}[\max(0, -\xi_n)^{2+\alpha}] < +\infty\) (see Proposition 3.2).

(ii) The function \(N_0 \rightarrow \mathbb{N}_0, x \mapsto x\), belongs to \(\mathcal{B}_\alpha\); this imposes the condition \(\alpha \geq 1\) (see Proposition 3.4).

Eventually, we fix \(\alpha = 1\) from Section 1.1 on.

**Notations.** Throughout the text, we use the following notations. Let \(u = (u_n)_{n \geq 0}\) and \(v = (v_n)_{n \geq 0}\) be two sequences of positive reals; we write

- \(u \preceq v\) (or simply \(u \leq v\)) when \(u_n \leq cv_n\) for some constant \(c > 0\) and \(n\) large enough;
- \(u_n \sim v_n\) when \(\lim_{n \to +\infty} \frac{u_n}{v_n} = 1\);
- \(u_n \asymp v_n\) when \(\lim_{n \to +\infty} (u_n - v_n) = 0\).

## 2 Fluctuations of random walks and auxiliary estimates

### 2.1 On the fluctuation of random walks

Let \(h\) be the Green function of the random walk \((S(\ell_1))_{\ell \geq 0}\), called sometimes the “descending renewal function” of \(S\), defined by

\[
h(x) = \begin{cases} 
\sum_{\ell=0}^{+\infty} \mathbb{P}[S(\ell_1) \geq -x] & \text{if } x \geq 0, \\
0 & \text{otherwise.}
\end{cases}
\]  

(2)

The function \(h\) is harmonic for the random walk \((S(n))_{n \geq 0}\) killed when it reaches the negative half line \((-\infty; 0]\); namely, for any \(x \geq 0\),

\[
\mathbb{E}[h(x + \xi_1); x + \xi_1 > 0] = h(x).
\]

This holds for any oscillating random walk, possible without finite second moment.

Similarly, we denote \(\tilde{h}\) the ascending renewal function of the random walk \((S(n))_{n \geq 0}\) (i.e. the descending renewal function of \((-S(n))_{n \geq 0}\)).

Both functions \(h\) and \(\tilde{h}\) are increasing, \(h(0) = \tilde{h}(0) = 1\) and \(h(x) = O(x), \tilde{h}(x) = O(x)\) as \(x \to +\infty\) (see [2], p. 648).

We have also to take into account that the random walk \(S\) may start from another point than the origin; hence, for any \(x \geq 0\), we set \(\tau^S(x) := \inf\{n \geq 1 : x + S(n) < 0\}\); it holds

\[
[\tau^S(x) > n] = [L_n \geq -x],
\]

where \(L_n = \min(S(1), \ldots, S(n))\). The following result is a combination of Theorem 2 and Proposition 11 in [7] and Theorem A in [13] (see also Theorems II.6 and II.7 in [14]).
Lemma 2.1. For any \( x \geq 0 \),

1. \[
\mathbb{P}[\tau^{S}(x) > n] \sim c_1 \frac{h(x)}{\sqrt{n}} \quad \text{as} \quad n \to +\infty,
\]

where
\[
c_1 = \frac{1}{\sqrt{\pi}} \exp \left( \sum_{k=1}^{+\infty} \frac{1}{k} \left( \mathbb{P}[S(k) \geq 0] - \frac{1}{2} \right) \right).
\]

Moreover, there exists a constant \( C_1 > 0 \) such that for any \( x \geq 0 \) and \( n \geq 1 \),
\[
\mathbb{P}[\tau^{S}(x) > n] \leq \frac{h(x)}{\sqrt{n}}.
\]

2. There exist constants \( c_2, C_2 > 0 \) such that, for any \( x, y \geq 0 \),
\[
\mathbb{P}[\tau^{S}(x) > n, x + S(n) = y] \sim c_2 \frac{h(x)\tilde{h}(y)}{n^{3/2}} \quad \text{as} \quad n \to +\infty,
\]

and, for any \( n \geq 1 \),
\[
\mathbb{P}[\tau^{S}(x) > n, x + S(n) = y] \leq \frac{h(x)\tilde{h}(y)}{n^{3/2}}.
\]

Constants \( c_1 \) and \( c_2 \) are linked by the following relation
\[
c_1 = 2c_2 \sum_{y \geq 1} \tilde{h}(y)\mathbb{P}[y + \xi_1 < 0].
\]

Assertions (5) and (6) yield a precise estimate of the probability \( \mathbb{P}[\tau^{S}(x) = n] \) itself, and not only the tail of the distribution of \( \tau^{S} \) as in (3). As a direct consequence, the sequence of descending ladder epochs \( (\ell_l)_{l \geq 1} \) of the random walk \( (S(n))_{n \geq 0} \) satisfies some renewal theorem. Let us state these two consequences which enlighten the next section where similar statements concerning the successive epochs of reflections of the reflected random are proved.

Corollary 2.2. For any \( x \geq 0 \),
\[
\mathbb{P}[\tau^{S}(x) = n] \sim \frac{c_1}{2} \frac{h(x)}{n^{3/2}} \quad \text{as} \quad n \to +\infty,
\]

and there exists a constant \( C_3 > 0 \) such that, for any \( x \geq 0 \) and \( n \geq 1 \),
\[
\mathbb{P}[\tau^{S}(x) = n] \leq \frac{h(x)}{n^{3/2}}.
\]

Furthermore,
\[
\sum_{l=0}^{+\infty} \mathbb{P}[\ell_l = n] \sim \frac{1}{c_1 \pi} \frac{1}{\sqrt{n}} \quad \text{as} \quad n \to +\infty.
\]

2.2 Conditional limit theorems

We recall the following result, which is a consequence of Lemma 2.3 in [2]. The symbol “\( \Rightarrow \)” means “weak convergence”.

Lemma 2.3. Assume \( \mathbb{E}[\xi^2] < +\infty \) and \( \mathbb{E}[\xi] = 0 \). Then, for any \( x \geq 0 \), and any bounded and Lipschitz continuous function \( \phi : \mathbb{R} \to \mathbb{R} \),
\[
\lim_{n \to +\infty} \mathbb{E} \left[ \phi \left( \frac{x + S(n)}{\sigma \sqrt{n}} \right) \mathbb{I}_{\tau^{S}(x) > n} \right] = \int_0^{+\infty} \phi(z) e^{-z^2/2} dz.
\]
This Lemma is useful in the sequel to control the fluctuations of the excursions of the process \((X(n))_{n \geq 0}\) between two successive times of reflection. In order to control also the higher-dimensional distributions of these excursions, we need the following statement which corresponds in our setting to Corollary 2.5 in [5].

**Lemma 2.4.** For any bounded, Lipschitz continuous function \(\phi : \mathbb{R} \to \mathbb{R}\), any \(x, y \geq 0\), and any \(t > s > 0\),

\[
\lim_{n \to +\infty} \mathbb{E} \left[ \phi \left( \frac{x + S([ns])}{\sigma \sqrt{n}} \right) \right] = \int_0^{+\infty} 2\phi(u)\exp\left( -\frac{u^2}{2} \right) du.
\]

### 3 On the sub-process of reflections

We present briefly some results from [8] and [16]. The reflected times \(r_n, n \geq 0\), of the random walk \((X(n))_{n \geq 0}\) are defined by: for any \(x \geq 0\),

\[
r_0 = r_0(x) = 0 \quad \text{and} \quad r_{n+1} = \inf\{m > r_n \mid X(r_n) + \xi_{r_n+1} + \ldots + \xi_m < 0\}.
\]

Notice that these random variables are \(\mathbb{N}_0 \cup \{+\infty\}\)-valued stopping times with respect to the filtration \((\mathcal{G}_n)_{n \geq 0}\).

When \(\mathbb{E}[|\xi_n|] < +\infty\) and \(\mathbb{E}[^\xi_n] = 0\), the random walk \((S(n))_{n \geq 0}\) is oscillating, hence the \(r_n, n \geq 0\), are all finite \(\mathbb{P}\)-a.s. and \(S(n)/n\) converges \(\mathbb{P}\)-a.s towards 0. Notice that \(0 \leq |S(n)| \leq X_n\) holds for any \(x \in \mathbb{N}_0\) so that the strong law of large number for \(S(n)\) does not yield directly the same statement for \(X_n\). Nevertheless, the strong law of large numbers is still true for the reflected random walk on \(\mathbb{N}_0\):

**Lemma 3.1.** If \(\mathbb{E}[|\xi_n|] < +\infty\) and \(\mathbb{E}[^\xi_n] = 0\), then, for any \(x \in \mathbb{N}_0\),

\[
\lim_{n \to +\infty} \frac{X_n}{n} = 0 \quad \mathbb{P}\text{-a.s.}
\]

**Proof.** For any \(n \geq 1\), there exits a (random) integer \(k_n \geq 1\) such that \(r_{k_n} \leq n < r_{k_n+1}\). It holds

\[
X_n = X_{r_{k_n}} + (\xi_{r_{k_n}+1} + \ldots + \xi_n) = X_{r_{k_n}} + S(n) - S(r_{k_n}),
\]

so that

\[
0 \leq \frac{X_n}{n} = \frac{X_{r_{k_n}}}{n} + \frac{S(n)}{n} - \frac{S(r_{k_n})}{n} \leq \frac{\max(|\xi_1|, \ldots, |\xi_n|)}{n} + \frac{S(n)}{n} - \frac{S(r_{k_n})}{n}.
\]

The first term on the right-hand side converges \(\mathbb{P}\)-a.s. towards 0 since \(\mathbb{E}[|\xi_n|] < +\infty\). By the strong law of large number, the second term tends \(\mathbb{P}\)-a.s. to 0. At last, the same property holds for the last term, since

\[
\left| \frac{S(r_{k_n})}{r_{k_n}} \right| = \frac{S(r_{k_n})}{r_{k_n}} \times \frac{r_{k_n}}{n} \leq \left| \frac{S(r_{k_n})}{r_{k_n}} \right|.
\]

The sub-process of reflections is the sequence \((X(r_k))_{k \geq 0}\): this is a Markov chain on \(\mathbb{N}_0\) with transition probability \(\mathcal{R}\) given by: for all \(x, y \in \mathbb{N}_0\),

\[
\mathcal{R}(x, y) = \begin{cases} 
0 & \text{if } y = 0 \\
\sum_{w=0}^{x} U^*(w - x - y) \mu^*(w) & \text{if } y \geq 1,
\end{cases}
\]

where \(\mu^*\) is the distribution of \(S(\ell_1)\) and \(U^* = \sum_{n=0}^{+\infty} (\mu^*)^n\) denotes its potential.

Set \(C := \sup\{y \geq 1 : \mu(-y) > 0\}\). The support of \(\mu^*\) equals \(Z^- = \mathbb{Z} \cap (-\infty, 0)\) when \(C = +\infty\), otherwise it is \([-C, \ldots, -1]\); furthermore, \(U^*(-w) > 0\) for any \(w \geq 0\). Then, \(\mathcal{R}(x, y) > 0\) if and only
if \( y \in S_r \), where \( S_r = \mathbb{N}_0 \) when \( C = +\infty \) and \( S_r = \{1, \ldots, C\} \) otherwise. Consequently, the set \( S_r \) is the unique irreducible and ergodic class of the Markov chain \((X(r_k))_{k \geq 0}\) and this chain is aperiodic on \( S_r \).

The measure \( \nu \) on \( \mathbb{N}_0 \) defined by
\[
\nu(x) = \sum_{y=1}^{+\infty} \left( \frac{1}{2} \mu^*(x) + \mu^*\left((-x-y, -x)\right) + \frac{1}{2} \mu^*(-x-y) \right) \mu^*(-y),
\]
is, up to a multiplicative constant, the unique stationary measure for \((X(r_k))_{k \geq 0}\); its support equals \( S_r \).

When \( \nu \) is finite, we normalize it in such a way it is a probability measure. It holds in particular when \( \mathbb{E}[|S(\ell_1)|^{1/2}] < \infty \) and \( \mathbb{E}[\xi_n] = 0 \), in which case the process of reflections is positive recurrent on \( S_r \).

### 3.1 On the spectrum of the transition probabilities matrix \( \mathcal{R} \)

Let us recall some spectral properties of the matrix \( \mathcal{R} = (\mathcal{R}(x, y))_{x, y \in \mathbb{N}_0} \). By Property 2.3 in [8], the matrix \( \mathcal{R} \) is quasi-compact on the space \( L^\infty(\mathbb{N}_0) \) of bounded functions on \( \mathbb{N}_0 \), with 1 as the unique (and simple) dominant eigenvalue; in particular, the rest of the spectrum of \( \mathcal{R} \) is included in a disc with radius \( < 1 \).

It is of interest in the next section to let \( \mathcal{R} \) act on a bigger space than \( L^\infty(\mathbb{N}_0) \).

For instance, following [8], we may fix \( K > 1 \) and consider the Banach space
\[
L_K(\mathbb{N}_0) := \{ \phi : \mathbb{N}_0 \to \mathbb{C} : ||\phi||_K := \sup_{x \geq 0} |\phi(x)|/K^x < +\infty \}
\]
endowed with the norm \( || \cdot ||_K \). By Property 2.3 in [8], if \( \sum_{x \geq 0} K^x \mu(x) < +\infty \) then \( \mathcal{R} \) acts as a compact operator on \( L_K(\mathbb{N}_0) \).

In this article, we only assume that \( \mu \) has a finite moment of order \( 2 \) and its negative part has moment of order \( 3 \). Consequently, we consider a smaller Banach space \( \mathcal{B}_\alpha \) adapted to these hypotheses and defined by: for \( \alpha > 0 \) fixed,
\[
\mathcal{B}_\alpha := \{ \phi : \mathbb{N}_0 \to \mathbb{C} : ||\phi||_\alpha := \sup_{x \geq 0} \frac{|\phi(x)|}{1 + x^\alpha} < +\infty \}.
\]
Endowed with the norm \( || \cdot ||_\alpha \), the space \( \mathcal{B}_\alpha \) is a Banach space on \( \mathbb{C} \).

**Proposition 3.2.** Fix \( \alpha > 0 \) and assume \( \mathbb{E}[\xi_n^2] + \mathbb{E}[\max(0, -\xi_n)^{2+\alpha}] < +\infty \) and \( \mathbb{E}[\xi_n] = 0 \). Then, the operator \( \mathcal{R} \) acts on \( \mathcal{B}_\alpha \) and \( \mathcal{R}(\mathcal{B}_\alpha) \subset L^\infty(\mathbb{N}_0) \). Furthermore,

1. \( \mathcal{R} \) is compact on \( \mathcal{B}_\alpha \) with spectral radius 1;
2. 1 is the unique eigenvalue of \( \mathcal{R} \) with modulus 1, it is simple with corresponding eigenspace \( \mathbb{C}1 \);
3. the rest of the spectrum of \( \mathcal{R} \) on \( \mathcal{B}_\alpha \) is included in a disc with radius \( < 1 \).

Let \( \Pi \) be the projection from \( \mathcal{B}_\alpha \) onto the eigenspace \( \mathbb{C}1 \) corresponding to this spectral decomposition, i.e. such that \( \Pi \mathcal{R} = \mathcal{R} \Pi = \Pi \). In other words, there exists a bounded operator \( \mathcal{Q} \) on \( \mathcal{B}_\alpha \) with spectral radius \( < 1 \) such that \( \mathcal{R} \) may be decomposed as follows:
\[
\mathcal{R} = \Pi + \mathcal{Q}, \quad \Pi \mathcal{Q} = \mathcal{Q} \Pi = 0 \quad \text{with} \quad \Pi(\cdot) = \nu(\cdot)1.
\] (9)

In the next section, we require that \( \mathcal{B}_\alpha \) does contain the descending and ascending renewal functions \( h \) and \( \hat{h} \) of the random walk \( S \). This imposes in particular that \( \alpha \) is greater or equal to \( 1 \).
Proof. (1) By (8), for any $\phi \in B_\alpha$ and $x \geq 0$,
\[
\mathcal{R}\phi(x) = \sum_{y \geq 1} \sum_{w=0}^{+\infty} U^*(-w)\mu^*(w-x-y)\phi(y)
\]
with $U^*(-w) = \sum_{n=0}^{+\infty} P[S(l_n) = -w] = P[\bigcup_{n \geq 0}[S(l_n) = -w]] \leq 1$. Therefore,
\[
|\mathcal{R}\phi(x)| \leq \sum_{y \geq 1} \sum_{w=0}^{+\infty} \mu^*(w-x-y)|\phi(y)| \\
\leq \sum_{y \geq 1} \mu^*((-\infty,-y))|\phi(y)| \\
\leq \left( \sum_{y \geq 1} (1 + y\alpha)\mu^*((-\infty,-y)) \right) |\phi|_\alpha.
\]

By Theorem 1 in [6], the condition $\mathbb{E}[\max(0, -\xi_n)^{2+\alpha}] < +\infty$ implies $\mathbb{E}[|S(l_1)|^{1+\alpha}] < +\infty$; hence,
\[
\sum_{y \geq 1} (1 + y\alpha)\mu^*((-\infty,-y)) = \mathbb{E}[|S(l_1)|] + \mathbb{E}[|S(l_1)|^{1+\alpha}] < +\infty.
\]

Consequently,
\[
|\mathcal{R}\phi|_\alpha \leq |\mathcal{R}\phi|_\infty \leq \left( \mathbb{E}[|S(l_1)|] + \mathbb{E}[|S(l_1)|^{1+\alpha}] \right) |\phi|_\alpha \tag{10}
\]
which proves that $\mathcal{R}$ acts on $B_\alpha$ when $\mathbb{E}[\max(0, -\xi_n)^{2+\alpha}] < +\infty$. More precisely, the operator $\mathcal{R}$ is bounded from $B_\alpha$ into $L^\infty(\mathbb{N}_0)$ and since the canonical injection $L^\infty(\mathbb{N}_0) \hookrightarrow B_\alpha$ is compact, the operator $\mathcal{R}$ is compact on $B_\alpha$.

Let us now check that $\mathcal{R}$ has spectral radius $\rho_\alpha = 1$ on $B_\alpha$. On the one hand, the equality $\mathcal{R}1 = 1$, with $1 \in B_\alpha$, yields $\rho_\alpha \geq 1$. On the other hands, $\mathcal{R}$ is a power bounded operator on $B_\alpha$, which readily implies $\rho_\alpha \leq 1$; indeed, for any $n \geq 1$,
\[
|\mathcal{R}^n\phi(x)| \leq \sum_{z=0}^{+\infty} \mathcal{R}^{n-1}(x,z)|\mathcal{R}\phi(z)| \leq |\mathcal{R}\phi|_\infty \sum_{z=0}^{+\infty} \mathcal{R}^{n-1}(x,z) = |\mathcal{R}\phi|_\infty,
\]
which yields, combining with (10),
\[
|\mathcal{R}^n\phi|_\alpha \leq |\mathcal{R}\phi|_\infty \leq \left( \mathbb{E}[|S(l_1)|] + \mathbb{E}[|S(l_1)|^{1+\alpha}] \right) |\phi|_\alpha.
\]
Consequently, denoting $\|\mathcal{R}^n\|_\alpha$ the norm of $\mathcal{R}^n$ on $B_\alpha$, it holds
\[
\sup_{n \geq 0} \|\mathcal{R}^n\|_\alpha \leq \left( \mathbb{E}[|S(l_1)|] + \mathbb{E}[|S(l_1)|^{1+\alpha}] \right) < +\infty.
\]
This achieves the proof of assertion 1.

(2) Let us control the peripheral spectrum of $\mathcal{R}$ in $B_\alpha$. Let $\theta \in \mathbb{R}$ and $\phi \in B_\alpha$ such that $\mathcal{R}\phi = e^{i\theta}\phi$.

By (10), the function $\mathcal{R}\phi$ is bounded, so is $\phi$. Furthermore, the operator $\mathcal{R}$ being positive, it holds $|\phi| \leq |\mathcal{R}||\phi|$. Consequently, the function $|\phi|_\infty - |\phi|$ is super-harmonic and non-negative, hence constant since the Markov chain $(X_{r_n})_{n \geq 0}$ is irreducible and recurrent on this set.

Without loss of generality, we may assume $|\phi| = 1$ on $S_r$, i.e $\phi(x) = e^{i\varphi(x)}$ for any $x \in S_r$, with $\varphi : S_r \rightarrow \mathbb{R}$. Equality $\mathcal{R}\phi = e^{i\theta}\phi$ may be rewritten as: for any $x \in S_r$,
\[
\sum_{y \in S_r} e^{i(\varphi(y) - \varphi(x))}\mathcal{R}(x, y) = e^{i\theta}.
\]
Recall that $\mathcal{R}(x, y) > 0$ for any $x, y \in \mathbb{S}_r$; thus, by convexity, $e^{i(\varphi(y) - \varphi(x))} = e^{i\theta}$ for any $x, y \in \mathbb{S}_r$. Thus, $e^{i\theta} = 1$ and the function $\phi$ is harmonic on $\mathbb{S}_r$, hence constant. Eventually, the function $\phi$ is constant on $\mathbb{N}_0$: this is the consequence of equality $\mathcal{R}\phi(x) = e^{i\theta}\phi(x) = \phi(x)$, valid for any $x \in \mathbb{N}_0$, combined with the facts that $\mathcal{R}(x, y) > 0$ if and only if $y \in \mathbb{S}_r$ and that $\phi$ is constant on $\mathbb{S}_r$.

(3) Assertion 3 is a consequence of assertion 2 and the compactness of $\mathcal{R}$ on $\mathcal{B}_n$.

\[ \square \]

### 3.2 A Renewal limit theorem for the times of reflections

In this section, we prove the analogous of Corollary 2.2 for the process $(r_n)_{n \geq 0}$. Let us introduce some notations and conventions.

From now on, we focus on the process $(X(n))_{n \geq 0}$ and denote

\[ ((\mathbb{N}^0) \otimes \mathbb{N}, (\mathcal{P}(\mathbb{N}^0)) \otimes \mathbb{N}, (X(n))_{n \geq 0}, (\mathbb{P}_x)_{x \in \mathbb{N}_0}, \theta) \]

the canonical space associated to this process, that is the space of trajectories of the Markov chain $(X(n))_{n \geq 0}$. In particular, $\mathbb{P}_x, x \in \mathbb{N}_0$, denotes the conditional probability with respect to the event $[X_0 = x]$ and $\mathbb{E}_x$ the corresponding conditional expectation. The operator $\theta$ is the classical shift transformation defined by: for any $(x_k)_{k \geq 0} (\mathbb{N}^0) \otimes \mathbb{N}$,

\[ \theta((x_k)_{k \geq 0}) = ((x_{k+1})_{k \geq 0}. \]

For $n, x, y \geq 0$, set

\[ R_n(x, y) := \mathbb{P}_x[r_1 = n, X(n) = y], \]

and

\[ \Sigma_n(x, y) := \sum_{k=1}^{+\infty} \mathbb{P}_x[r_k = n, X(n) = y]. \]

We are interested in the behavior as $n \rightarrow +\infty$ of these quantities. It has been already studied in [13] (see Lemma 7) for the Lindley process. For the reflected random walk, the argument is more complicated since the position at time $r_k$ may vary, which implies that the excursions of the random walk $(X(n))_{n \geq 0}$ between two successive reflection times are not independent. This explain why we focus here on the reflection process and it is of interest to express quantities $R_n(x, y)$ and $\Sigma_n(x, y)$ in terms of operators and product of operators related to this sub-process.

We consider the linear operators $R_n : \mathbb{L}^\infty(\mathbb{N}_0) \rightarrow \mathbb{L}^\infty(\mathbb{N}_0)$, $n \geq 0$, defined by: for any $\phi \in \mathbb{L}^\infty(\mathbb{N}_0)$ and $x \geq 0$,

\[ R_n\phi(x) = \sum_{y \geq 1} R_n(x, y)\phi(y) = \mathbb{E}_x[r_1 = n; \phi(X(n))]. \tag{11} \]

In particular, $R_n(x, y) = R_n1_{\{y\}}(x)$. The quantity $\Sigma_n(x, y)$ is also expressed in terms of the $R_k$ as follows:

\[ \Sigma_n(x, y) = \sum_{k=1}^{+\infty} \mathbb{P}_x[r_k = n, X(n) = y] \]

\[ = \sum_{k=1}^{+\infty} \sum_{j_1 + \ldots + j_k = n} \mathbb{P}_x[r_1 = j_1, r_2 - r_1 = j_2, \ldots, r_k - r_{k-1} = j_k, X(n) = y] \]

\[ = \sum_{k=1}^{+\infty} \sum_{j_1 + \ldots + j_k = n} R_{j_1} \ldots R_{j_k}1_{\{y\}}(x) \tag{12} \]

Firstly, let us check that the $R_n$ act on $\mathcal{B}_n$. 

8
Lemma 3.3. There exists a positive constant $C_4$ such that, for any $\alpha > 0$,

$$|R_n|_\alpha \leq C_4 \frac{\mathbb{E} \left[ \max(0, -\xi_n)^{2+\alpha} \right]}{n^{3/2}}. \quad (13)$$

Proof. For any $\phi \in B_\alpha$ and $x \geq 0$,

$$|R_n \phi(x)| \leq \sum_{y \geq 1} |\phi(y)| \mathbb{P}_x [r_1 = n, X(n) = y]$$

$$= \sum_{y \geq 1} \sum_{z \geq 0} |\phi(y)| \mathbb{P}[x^z(x) \geq n - 1, x + S(n - 1) = z, z + \xi_n = -y]$$

$$= \sum_{y \geq 1} \sum_{z \geq 0} |\phi(y)| \mathbb{P}[x^z(x) \geq n - 1, x + S(n - 1) = z] \mathbb{P}[\xi_n = -y - z].$$

Hence, by Lemma 2.1,

$$\frac{|R_n \phi(x)|}{1 + x^\alpha} \leq \frac{1}{n^{3/2}} \sum_{y \geq 1} \sum_{z \geq 0} |\phi(y)| \frac{h(x)}{1 + x^\alpha} \hat{h}(z) \mathbb{P}[\xi_1 = -y - z].$$

Since $h(x) = O(x)$ and $\hat{h}(z) = O(z)$,

$$\frac{|R_n \phi(x)|}{1 + x^\alpha} \leq \frac{|\phi|_\alpha}{n^{3/2}} \sum_{y \geq 1} \sum_{z \geq 0} (1 + y^\alpha) \hat{h}(z) \mathbb{P}[\xi_1 = -y - z]$$

$$\leq \frac{|\phi|_\alpha}{n^{3/2}} \sum_{y \geq 1} \sum_{z \geq 0} (1 + y^\alpha) z \mathbb{P}[\xi_1 = -y - z]$$

$$= \frac{|\phi|_\alpha}{n^{3/2}} \sum_{t \geq 1} \sum_{y = 1}^{t} (1 + y^\alpha)(t - y) \mathbb{P}[\xi_1 = -t]$$

$$\leq \frac{|\phi|_\alpha}{n^{3/2}} \sum_{t \geq 1} t^{2+\alpha} \mathbb{P}[\xi_1 = -t],$$

which yields (13).

Hence, $\sum_{n \geq 0} |R_n|_\alpha < +\infty$; in particular, the sequence $(\sum_{n=1}^N R_n)_{N \geq 1}$ converges towards $R$ in $B_\alpha$.

We write $R = \sum_{n \geq 1} R_n$ and, for any $z \in \overline{B} := \{z \in \mathbb{C} : |z| \leq 1\}$, we set

$$R(z) = \sum_{n \geq 1} z^n R_n.$$

Proposition 3.4. Fix $\alpha > 0$ and assume $\mathbb{E}[\xi_n^2] + \mathbb{E}[\max(0, -\xi_n)^{2+\alpha}] < +\infty$ and $\mathbb{E}[\xi_n] = 0$. The sequence $(R_n)_{n \geq 0}$ is an aperiodic renewal sequence of operators, i.e. it satisfies the following properties (see (9)):

(R1). The operator $R = R(1)$ has a simple eigenvalue at 1 and the rest of its spectrum is contained in a disk of radius < 1.

(R2). For any $n \geq 1$, set $r_n := \nu R_n 1 = \sum_{x \geq 1} \nu(x) \mathbb{P}_x (r_1 = n)$; hence,

$$\Pi R_n \Pi = r_n \Pi,$$

where $\Pi$ denotes the eigenprojection of $R$ for the eigenvalue 1.

(R3). There exists a constant $C > 0$ such that $|R_n|_\alpha \leq \frac{C}{n^{\gamma}}$.

(R4). $\sum_{j \geq n} r_j \sim \frac{c_1}{\sqrt{n}}$ with $c_1 = c_1 \nu(h)$, where $c_1$ is the positive constant given by Lemma 2.1 and $h$ is the descending renewal function of the random walk $S$.

(R5). The spectral radius of $R(z)$ is strictly less than 1 for $z \in \overline{B} \setminus \{1\}$.
Proof. (R1) is a direct consequence of Proposition 3.2.

(R2) Recall that $\Pi \phi = \nu(\phi)1$ for any $\phi \in B_\alpha$. Hence, setting $g_n(x) := \mathbb{P}_x(R_1 = n)$, it holds

$$R_n \Pi \phi(x) = \nu(\phi)g_n(x), \quad \text{thus} \quad \Pi R_n \Pi \phi(x) = \nu(\phi)\Pi(g_n) = \sum_{x \geq 1} \nu(x)\mathbb{P}_x(r_1 = n)\nu(\phi)1,$$

which is the expected result.

(R3) follows from Lemma 3.3.

(R4) Thanks to Lemma 2.1,

$$\sum_{j \geq n} r_j = \sum_{x \geq 1} \sum_{y \geq n} \nu(x)\mathbb{P}_x[r_1 = j] = \sum_{x \geq 1} \frac{\nu(x)\mathbb{P}_x[r_1 \geq n]}{n} \sim c_1 \frac{\nu(h)}{\sqrt{n}} \quad \text{as} \quad n \to +\infty.$$

Notice that $0 < \nu(h) < +\infty$ since $\mathbb{E}[|S(\ell_1)|] < +\infty$; indeed, $1 \leq h(x) = O(x)$ and

$$\sum_{x \geq 1} \nu(x) \leq \sum_{x \geq 1} \sum_{y \geq x} \sum_{w = x}^{x+y} \mu^*(w)\mu^*(-y) = \sum_{y \geq 1} \sum_{w \geq 1} \mu^*(w)\mu^*(-y) \sum_{x = (w-y)\vee 0}^w x \leq \sum_{y \geq 1} \sum_{w \geq 1} yw \mu^*(w)\mu^*(-y) = \left(\sum_{y \geq 1} y \mu^*(-y)\right)^2 \leq (\mathbb{E}[|S(\ell_1)|])^2 < +\infty.$$

(R5) The argument is the same as the one used to control the peripheral spectrum of $R$ in Proposition 3.2. For any $z \in \overline{\mathbb{D}} \setminus \{1\}$, the operators $R(z)$ are compact on $B_\alpha$, with spectral radius $\rho_z \leq 1$.

If $\rho_z = 1$, there exist $\theta \in \mathbb{R}$ and $\phi \in B_\alpha$ such that $R(z)\phi = e^{i\theta}\phi$. Hence $|\phi| = |R(z)\phi| \leq R|\phi|$ and since $R(B_\alpha) \subset L^\infty(N_0)$, the function $|\phi|$ is bounded on $N_0$, thus constant on $S_r$.

Without loss of generality, we may assume $|\phi| = 1$ on $S_r$, i.e $\phi(x) = e^{i\varphi(x)}$ for any $x \in S_r$, with $\varphi : S_r \to \mathbb{R}$. Equality $R(z)\phi = e^{i\theta}\phi$ may be rewritten as: for any $x \in S_r$,

$$\sum_{n \geq 1} \sum_{y \in S_r} z^n e^{i\varphi(y)}\mathbb{P}_x(r_1 = n; X(n) = y) = e^{i\theta} e^{i\varphi(x)}.$$

By convexity, since $\sum_{n \geq 1} \sum_{y \in S_r} \mathbb{P}_x(r_1 = n; X(n) = y) = 1$, we obtain: for all $n \geq 1$ and $x, y \in S_r$,

$$z^n e^{i\varphi(y)} = e^{i\theta} e^{i\varphi(x)}.$$

Setting $x = y$, it yields $z^n = e^{i\theta}$, so that $z^n$ does not depend on $n$. Finally $z = 1$. Thus, $\rho_z < 1$ when $z \in \overline{\mathbb{D}} \setminus \{1\}$.

By (R5), for $|z| < 1$, the operator $T(z) := (I - R(z))^{-1}$ is well defined in $B_\alpha$; a direct formal computation yields $T(z) = \sum_{n \geq 0} T_n z^n$, where the $T_n$ are bounded operators on $B_\alpha$, defined by:

$$T_0 = I \quad \text{and} \quad T_n = \sum_{k=1}^{+\infty} \sum_{j_1 + \cdots + j_k = n} R_{j_1} \cdots R_{j_k} \quad \text{for} \quad n \geq 1.$$

The so-called renewal equation $T(z) := (I - R(z))^{-1}$ is of fundamental importance to understand the asymptotics of the $T_n$, several functional analytic tools can be brought into play. Such sequences of operators $(R_n)_{n \geq 0}$ and $(T_n)_{n \geq 0}$ have been the object of many studies, related to renewal theory in a non-commutative setting. We refer to the paper [9], which fits perfectly here. The following statement is analogous of the last assertion of Corollary 2.2 for the reflected random walk.

**Corollary 3.5.** The sequence $(\sqrt{n}T_n)_{n \geq 1}$ converges in $B_\alpha$ towards the operator $\frac{1}{\pi c_1 \nu(h)}\Pi$.

**Proof.** Apply Theorem 1.4 in [9] with $\beta = 1/2$ and $\ell(n) = c = c_1 \nu(h)$. 

\[ \square \]
As a direct consequence, by equality \textbf{(12)}, it holds

\[
\lim_{n \to +\infty} \sqrt{n} \Sigma_n(x, y) = \frac{\nu(y)}{\pi c_1 \nu(h)}.
\]

In the next section, we have to consider and study some variations of the \(\Sigma_n(x, y)\) which we introduce now. For any \(x \geq 0\) and \(0 < s < t < 1\),

\[
\tilde{\Sigma}_n(x, t, s) := n \sum_{l \geq 0} [n^t, r_{l+1} > [nt]],
\]

and

\[
\bar{\Sigma}_n(x, t, s) := n^2 \sum_{l \geq 0} [n^t, r_{l+1} = [nt]].
\]

These quantities appear in a natural way to control the finite distribution of the process \((X_n(t))_{n \geq 0}\).

\section{Proof of Theorem 1.1}

From now on, we fix \(\alpha = 1\); this implies that \(h \in B_\alpha\), which is necessary from now on (see Lemmas 4.2 and 4.4).

\subsection{One-dimensional distribution}

We fix a bounded and Lispchitz continuous function \(\phi : \mathbb{R} \to \mathbb{R}\).

\textbf{Lemma 4.1.} For any \(t \in [0, 1]\), it holds

\[
\lim_{n \to +\infty} \mathbb{E}_x [\phi (X_n(t))] = \int_0^{+\infty} \phi(u) \frac{2e^{-u^2/2t}}{\sqrt{2\pi t}} du = \mathbb{E}[\phi(|B_t|)],
\]

where \(B\) is a standard Brownian motion.

\textbf{Proof.} We fix \(t \in (0, 1)\) and decompose the expectation \(\mathbb{E} \left[ \phi \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \right]\) as follows:

\[
\mathbb{E}_x \left[ \phi \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \right] \\
\approx \sum_{k=0}^{[nt]-1} \sum_{l \geq 0} \mathbb{E}_x \left[ \phi \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) : r_l = k, X(k) + \xi_{k+1} \geq 0, \ldots, X(k) + \xi_{[nt]} \geq 0 \right] \\
= \sum_{k=0}^{[nt]-1} \sum_{y \geq 0} \Sigma_k(x, y) \mathbb{E} \left[ \phi \left( \frac{y + \xi_{k+1} + \ldots + \xi_{[nt]}}{\sigma \sqrt{n}} \right) : y + \xi_{k+1} \geq 0, \ldots, y + \xi_{k+1} + \ldots + \xi_{[nt]} \geq 0 \right] \\
= \sum_{k=0}^{[nt]-1} \sum_{y \geq 0} \Sigma_k(x, y) \mathbb{E} \left[ \phi \left( \frac{y + S([nt] - k)}{\sigma \sqrt{n}} \right) : \tau^S(y) > [nt] - k \right] \mathbb{P} [\tau^S(y) > [nt] - k].
\]

For each \(k = 2, \ldots, [nt] - 4\) and any \(s \in \left[ \frac{k}{n}, \frac{k+1}{n} \right)\),

\[
f_n(s) = n \sum_{y \geq 0} \Sigma_{[ns]}(x, y) \mathbb{E} \left[ \phi \left( \frac{y + S([nt] - [ns])}{\sigma \sqrt{n}} \right) : \tau^S(y) > [nt] - [ns] \right] \mathbb{P} [\tau^S(y) > [nt] - [ns]],
\]
and \( f_n(s) = 0 \) on \([0, \frac{2}{n}]\) and \([\lceil nt \rceil - \frac{1}{n}, t)\). Hence,
\[
\mathbb{E}_x \left[ \phi \left( \frac{X(\lceil nt \rceil)}{\sigma \sqrt{n}} \right) \right] = \int_0^t f_n(s) ds + O \left( \frac{1}{\sqrt{n}} \right).
\]

Now, let us set: for \( n \geq 1 \) and any \( y \in \mathbb{N}_0 \),
\[
a_n(y) = \Sigma_{[nt]}(x, y) \mathbb{P} \left[ \tau^S(y) > [nt] - [ns] \right],
\]
\[
b_n(y) = \mathbb{E} \left[ \phi \left( \frac{y + S([nt] - [ns])}{\sigma \sqrt{n}} \right) \right] \mathbb{P} \left[ \tau^S(y) > [nt] - [ns] \right].
\]

For any \( n \geq 1 \), it holds
\[
\sum_{y \geq 0} a_n(y) = n \sum_{l \geq 0} \mathbb{P}_x [r_l = [ns], r_{l+1} > [nt]] =: \tilde{\Sigma}_n(x, t, s),
\]
and \( |b_n(y)| \leq |\phi|_\infty \). The 2 following lemmas allow us to control the behavior as \( n \to +\infty \) of the integral \( \int_0^t f_n(s) ds \); the proof of Lemma 4.2 is postponed to the last section, the one of 4.3 is straightforward.

**Lemma 4.2.** For each \( 0 < s < t < 1 \),
\[
\lim_{n \to +\infty} \tilde{\Sigma}_n(x, t, s) = \frac{1}{\pi \sqrt{s(t-s)}}.
\]
Moreover, there exists a positive constant \( C_5 \) such that
\[
\tilde{\Sigma}_n(x, t, s) \leq C_5 \frac{1 + x}{\sqrt{s(t-s)}} \text{ for all } 0 < s < t < 1 \text{ and } x \in \mathbb{N}.
\]

**Lemma 4.3.** Let \((a_n(y))_{y \in \mathbb{N}_0^k}, (b_n(y))_{y \in \mathbb{N}_0^k}\) be arrays of real numbers for some integer \( k \geq 1 \). Suppose that

- \( a_n(y) \geq 0 \);
- \( \lim_{n \to +\infty} \sum_{y \in \mathbb{N}_0^k} a_n(y) = A \);
- \( \lim_{n \to +\infty} b_n(y) = B \) for all \( y \in \mathbb{N}_0^k \);
- \( \sup_{n \geq 1, y \in \mathbb{N}_0^k} |b_n(y)| < +\infty \).

Then
\[
\lim_{n \to +\infty} \sum_{y \geq 0} a_n(y)b_n(y) = AB.
\]

Lemmas 2.3, 4.2 and 4.3 combined altogether yield: for any \( s \in (0, t) \),
\[
\lim_{n \to +\infty} f_n(s) = \frac{1}{\pi \sqrt{s(t-s)}} \int_0^{+\infty} \phi(z \sqrt{t-s}) ze^{-z^2/2} dz.
\]
Moreover, it follows from (15) that
\[
\sup_n |f_n(s)| \leq C_5 \frac{1 + x}{\sqrt{s(t-s)}} |\phi|_\infty =: \hat{f}(s).
\]

Since \( \hat{f} \in L^1(0, t] \), the Lebesgue dominated convergence theorem yields
\[
\lim_{n \to +\infty} \mathbb{E}_x \left[ \phi \left( \frac{X(\lceil nt \rceil)}{\sigma \sqrt{n}} \right) \right] = \lim_{n \to +\infty} \int_0^t f_n(s) ds
\]
\[
= \frac{1}{\pi} \int_0^t \frac{1}{\sqrt{s(t-s)}} \left( \int_0^{+\infty} \phi(z \sqrt{t-s}) ze^{-z^2/2} dz \right) ds
\]
\[
= \int_0^{+\infty} \phi(u) \frac{2e^{-u^2/2t}}{\sqrt{2\pi t}} du,
\]
where the last equation follows from the identity ([11], p. 17)

\[ \int_0^{+\infty} \frac{1}{\sqrt{t}} \exp \left( -\alpha t - \frac{\beta}{t} \right) dt = \sqrt{\frac{\pi}{\alpha}} e^{-2\sqrt{\alpha\beta}} \quad (\alpha, \beta > 0) \] (16)

and some change of variable computation. We achieve the proof of Lemma 4.1 by noting that, since \( \phi \) is Lipschitz continuous (with Lipschitz coefficient \( [\phi] \)),

\[
\left| \mathbb{E}_x \left[ \phi \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \right] - \mathbb{E}_x \left[ \phi \left( X_n(t) \right) \right] \right| \leq [\phi] \mathbb{E}_x \left[ \frac{X([nt])}{\sigma \sqrt{n}} - X_n(t) \right] \\
\leq \frac{1}{\sigma \sqrt{n}} [\phi] \mathbb{E} \left[ |\xi_{[nt]+1}| \right] \to 0 \quad \text{as } n \to +\infty. \] (17)

\[\square\]

### 4.2 Two-dimensional distribution

The convergence of the finite-dimensional distributions of \((X_n(t))_{n\geq 1}\) is more delicate. We detail the argument for two-dimensional ones, the general case may be treated in a similar way.

Let us fix \(0 < s < t, n \geq 1\) and denote

\[ \kappa = \kappa(n, s) = \min \{ k > [ns] : X(k - 1) + \xi_k < 0 \}. \]

We write

\[ \mathbb{E}_x \left[ \phi_1 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \right] = A_1(n) + A_2(n), \]

where

\[
A_1(n) = \sum_{k=[ns]+1}^{[nt]} \mathbb{E}_x \left[ \phi_1 \left( \frac{X([ns])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) 1_{\{\kappa = k\}} \right], \\
A_2(n) = \mathbb{E}_x \left[ \phi_1 \left( \frac{X([ns])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) 1_{\{\kappa > [nt]\}} \right].
\]

The term \(A_1(n)\) deals with the trajectories of \(X_k, 0 \leq k \leq n\), which reflect between \([ns]+1\) and \([nt]\) while \(A_2(n)\) concerns the others trajectories.
4.2.1 Estimate of $A_1(n)$

As in the previous section, we decompose $A_1(n)$ as

$$A_1(n) = \sum_{k_1=0}^{[ns]-1} \sum_{k_2=[ns]}^{[nt]} \sum_{l=0}^{+\infty} \sum_{y \geq 1} \sum_{z \geq 1} \sum_{w \geq 0} \mathbb{E}_x \left[ \phi_1 \left( \frac{X([ns])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) ; r_l = k_1, X(k_1) = z, \right.$$  

$$z + \xi_{k_1+1} \geq 0, \ldots, z + \xi_{k_1+1} + \cdots + \xi_{k_2-2} \geq 0, z + \xi_{k_1+1} + \cdots + \xi_{k_2-1} = w, w + \xi_{k_2} = -y$$

$$= \sum_{k_1=0}^{[ns]-1} \sum_{k_2=[ns]}^{[nt]} \sum_{l=0}^{+\infty} \sum_{y \geq 1} \sum_{z \geq 1} \sum_{w \geq 0} \mathbb{E}_x \left[ \phi_1 \left( \frac{z + \xi_{k_1+1} + \cdots + \xi_{[ns]}}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + \xi_{k_2+1} + \cdots + \xi_{[nt]}}{\sigma \sqrt{n}} \right) ; r_l = k_1, X(k_1) = z, \right.$$  

$$z + \xi_{k_1+1} + \cdots + \xi_{k_2-1} = w, w + \xi_{k_2} = -y$$

Using the i.i.d. property of the sequence $(\xi_k)_{k \geq 1}$, we obtain

$$A_1(n) = \sum_{k_1=0}^{[ns]-1} \sum_{k_2=[ns]}^{[nt]} \Sigma_{k_1}(x, z) \sum_{k_2=[ns]}^{[nt]} \sum_{y \geq 1} \sum_{z \geq 1} \mathbb{E}_y \left[ \phi_2 \left( \frac{X([nt] - k_2)}{\sigma \sqrt{n}} \right) \right]$$  

$$\times \mathbb{E} \left[ \phi_1 \left( \frac{z + S([ns] - k_1)}{\sigma \sqrt{n}} \right) \right] \mathbb{P}[r^S(z) > k_2 - k_1 - 1, z + S(k_2 - k_1 - 1) = w] \mathbb{P}[\xi_1 = -$w$ - y].$$

For any $2 \leq k_1 < [ns] - 6$ and $[ns] \leq k_2 \leq [nt]$ and any $s_1 \in \left[\frac{k_1}{n}, \frac{k_1+1}{n}\right]$ and $s_2 \in \left[\frac{k_2}{n}, \frac{k_2+1}{n}\right)$, we write

$$f_n(s_1, s_2) = n^2 \sum_{z \geq 1} \Sigma_{[ns]}(x, z) \sum_{y \geq 1} \sum_{w \geq 0} \mathbb{E}_y \left[ \phi_2 \left( \frac{X([nt] - [ns_2])}{\sigma \sqrt{n}} \right) \right]$$  

$$\times \mathbb{E} \left[ \phi_1 \left( \frac{z + S([ns] - [ns_1])}{\sigma \sqrt{n}} \right) \right] \mathbb{P}[r^S(z) > [ns_2] - [ns_1] - 1, z + S([ns_2] - [ns_1] - 1) = w] \mathbb{P}[\xi_1 = -$w$ - y],$$

and $f_n(s_1, s_2) = 0$ for the others values of $k_1$, such that $0 \leq k_1 \leq [ns]$. Hence,

$$A_1(n) = \int_0^\sigma ds_1 \int_s^t ds_2 f_n(s_1, s_2) + O \left( \frac{1}{\sqrt{n}} \right).$$
It follows from Lemma 4.4 that, for each \( z, w \geq 0 \),
\[
\lim_{n \to +\infty} E \left[ \phi_1 \left( \frac{z + S([ns] - [ns_1])}{\sigma \sqrt{n}} \right) | \tau^S(z) > [ns_2] - [ns_1] - 1, z + S([ns_2] - [ns_1] - 1) = w \right] = \int_0^{+\infty} 2\phi_1(u\sqrt{s_2 - s_1}) \exp \left( -\frac{u^2}{2(s_2 - s_1)} \right) \frac{u^2}{\sqrt{2\pi(s_2 - s_1)^3}} du
\]
\[
= \frac{2}{\sqrt{2\pi}} \int_0^{+\infty} \phi_1(v) \exp \left( -\frac{v^2}{2(s_2 - s_1)} \right) \frac{v^2}{\sqrt{(s_2 - s_1)^3}} dv.
\]
By Lemma 4.1,
\[
\lim_{n \to +\infty} E_y \left[ \phi_2 \left( \frac{X([nt] - [ns_2])}{\sigma \sqrt{n}} \right) \right] = \int_0^{+\infty} \phi_2(u) \frac{2e^{-u^2/2(t-s_2)}}{\sqrt{2\pi(t-s_2)}} du.
\]
We set
\[
a_n(x, y, z, w) = n^2 \Sigma_{[ns_1]}(x, z) P \left[ \tau^S(z) > [ns_2] - [ns_1] - 1, z + S([ns_2] - [ns_1] - 1) = w \right] P[\xi_1 = -w - y],
\]
\[
b_n(y, z, w) = E_y \left[ \phi_2 \left( \frac{X([nt] - [ns_2])}{\sigma \sqrt{n}} \right) \right] \times E \left[ \phi_1 \left( \frac{z + S([ns] - [ns_1])}{\sigma \sqrt{n}} \right) | \tau^S(z) > [ns_2] - [ns_1] - 1, z + S([ns_2] - [ns_1] - 1) = w \right] = \Sigma_n(x, s_2, s_1). \]
Note that \( \sum_{z \geq 1} \sum_{y \geq 1} \sum_{w \geq 0} a_n(x, y, z, w) = \overline{\Sigma}_n(x, s_2, s_1) \). The behavior as \( n \to +\infty \) of the quantity \( \overline{\Sigma}_n(x, s_2, s_1) \) is given by the following Lemma, whose proof is postponed to the last section.

Lemma 4.4. For all \( 0 < s < t < 1 \), it holds that
\[
\lim_{n \to +\infty} \overline{\Sigma}_n(x, t, s) = \frac{1}{2\pi \sqrt{s(t-s)^3}}
\]
Moreover, there exists a positive constant \( C_0 \) such that, for all \( 0 < s < t < 1 \) and \( n \geq 0 \),
\[
\overline{\Sigma}_n(x, t, s) \leq C_0 \frac{1 + x}{\pi \sqrt{s(t-s)^3}}
\]
By Lemmas 4.4 and 4.3 we get \( \lim_{n \to +\infty} f_n(s_1, s_2) = f(s_1, s_2) \) where
\[
f(s_1, s_2) = \frac{1}{\pi^2 \sqrt{s_1}} \int_0^{+\infty} \phi_1(v) \exp \left( -\frac{v^2}{2(s_2-s_1)(s_2-s_1)} \right) \frac{v^2}{\sqrt{(s_2-s_1)^3(s_2-s_1)^2}} dv
\]
\[
\times \int_0^{+\infty} \phi_2(u) e^{-u^2/2(t-s_2)} \frac{u^2}{\sqrt{t-s_2}} du.
\]
Moreover, by using the estimate (19) and following the argument in the proof of Lemma 4.1, we can show that the sequence \( (f_n)_{n \geq 1} \) is uniformly bounded by a function which is integrable with respect to Lebesgue measure on \( [0, s] \times [s, t] \). Hence, using again the Lebesgue dominated convergence theorem, we get
\[
\lim_{n \to +\infty} A_1(n) = \frac{1}{\pi^2} \int_0^s ds_1 \int_s^t ds_2 f(s_1, s_2)
\]
\[
= \frac{1}{\pi^2} \int_0^s ds_1 \sqrt{s_1} \int_s^t ds_2 \int_0^{+\infty} \phi_1(v) \exp \left( -\frac{v^2}{2(s_2-s_1)(s_2-s_1)} \right) \frac{v^2}{\sqrt{(s_2-s_1)^3(s_2-s_1)^2}} dv
\]
\[
\times \int_0^{+\infty} \phi_2(u) e^{-u^2/2(t-s_2)} \frac{u^2}{\sqrt{t-s_2}} du dv.
\]
which yields, using again (16),

\[
\lim_{n \to +\infty} A_1(n) = \frac{2}{\pi \sqrt{s(t-s)}} \int_{0}^{+\infty} \int_{0}^{+\infty} \phi_1(v)\phi_2(u) e^{-v^2/2s} e^{-\frac{(v-u)^2}{2(s-t)}} \, dv \, du.
\]

(20)

4.2.2 Estimate of \(A_2(n)\)

We decompose \(A_2(n)\) as

\[
\sum_{y=0}^{+\infty} \sum_{k \leq [ns]} \sum_{l \geq 0} \mathbb{E}_x \left[ \phi_1 \left( \frac{X([ns])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right); r_l = k, X(k) = y, y + \xi_{k+1} \geq 0, \ldots, y + \xi_{k+1} + \cdots + \xi_{[nt]} \geq 0 \right]
\]

\[
= \sum_{y=0}^{+\infty} \sum_{k \leq [ns]} \mathbb{E}_x \left[ \phi_1 \left( \frac{y + \xi_{k+1} + \cdots + \xi_{[ns]}}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + \xi_{k+1} + \cdots + \xi_{[nt]}}{\sigma \sqrt{n}} \right); y + \xi_{k+1} \geq 0, \ldots, y + \xi_{k+1} + \cdots + \xi_{[nt]} \geq 0 \right] \sum_{l \geq 0} \mathbb{P}_x \left[ r_l = k, X(k) = y \right].
\]

Since \((\xi_k)\) is a i.i.d. sequence,

\[
A_2(n) = \sum_{y=0}^{+\infty} \sum_{k \leq [ns]} \mathbb{E}_x \left[ \phi_1 \left( \frac{y + S([ns] - k)}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + S([nt] - k)}{\sigma \sqrt{n}} \right); \tau^S(y) > [nt] - k \right].
\]

For \(u \in (0, s]\), we denote

\[
g_n(u) = n \sum_{y=0}^{+\infty} \sum_{[nu]} \mathbb{E}_x \left[ \phi_1 \left( \frac{y + S([ns] - [nu])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + S([nt] - [nu])}{\sigma \sqrt{n}} \right); \tau^S(y) > [nt] - [nu] \right].
\]

Now, let us compute the pointwise limit on \((0, s]\) of the sequence \((g_n)_{n \geq 1}\). We write \(g_n(u)\) as

\[
g_n(u) = n \sum_{y=0}^{+\infty} \sum_{[nu]} \mathbb{E}_x \left[ \phi_1 \left( \frac{y + S([ns] - [nu])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + S([nt] - [nu])}{\sigma \sqrt{n}} \right); \tau^S(y) > [nt] - [nu] \right] \times \mathbb{P}_y \left[ \tau^S(y) > [nt] - [nu] \right]
\]

We set

\[
a_n(x, y) = n \sum_{[nu]} \mathbb{E}_x \left[ \phi_1 \left( \frac{y + S([ns] - [nu])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + S([nt] - [nu])}{\sigma \sqrt{n}} \right); \tau^S(y) > [nt] - [nu] \right],
\]

and

\[
b_n(y) = \mathbb{E} \left[ \phi_1 \left( \frac{y + S([ns] - [nu])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{y + S([nt] - [nu])}{\sigma \sqrt{n}} \right); \tau^S(y) > [nt] - [nu] \right].
\]
Note that $\sum_{y=0}^{+\infty} a_u(y) = \Sigma_{[nu]}(x, t, u)$. Since $\phi_1, \phi_2$ are bounded and continuous on $\mathbb{R}$, it follows from Theorem 3.2 in [4] and Theorems 2.23 and 3.4 in [10] that

$$\lim_{n \to +\infty} b_n(y) = \lim_{n \to +\infty} \mathbb{E} \left[ \phi_1 \left( \frac{y + \Sigma([ns] - [nu]) \sqrt{|nt - [nu]|}}{\sigma \sqrt{|nt - [nu]|}} \right) \right] \times \phi_2 \left( \frac{y + \Sigma([nt] - [nu]) \sqrt{|nt - [nu]|}}{\sigma \sqrt{|nt - [nu]|}} \right) |\tau_s^x(y) > [nt] - [nu] | \right].$$

$$= \int_0^{+\infty} \int_0^{+\infty} \phi_1(y) \phi_2(z) \sqrt{t-u} e^{-\frac{y^2}{2(t-u)}} \left( e^{-\frac{(t-u)^2}{2(t-u)}} - e^{-\frac{(t-u+y)^2}{2(t-u)}} \right) dy dz.$$

Again, we can use the argument in the proof of Lemma 4.1 to show that the sequence $(g_n)$ converges pointwise to $g$ with

$$g(u) = \frac{1}{\pi^{3/2} \sqrt{2(t-s)}} \frac{1}{u(s-u)^{3/2}} \int_0^{+\infty} \int_0^{+\infty} \phi_1(y') \phi_2(z') e^{-\frac{y'^2}{2(t-s)}} \left( e^{-\frac{(t-s)^2}{2(t-s)}} - e^{-\frac{(t-s+y')^2}{2(t-s)}} \right) dy' dz'.$$

and $(g_n)$ is also dominated by a function which is integrable on $[0, s]$ with respect to the Lebesgue measure. Lebesgue's dominated convergence theorem yields

$$\lim_{n \to +\infty} A_2(n)$$

$$= \lim_{n \to +\infty} \frac{1}{n} \sum_{k \leq [ns]} g_n(k/n) = \int_0^s g(u) du$$

$$= \frac{1}{\pi^{3/2}} \frac{1}{\sqrt{2(t-s)}} \int_0^{+\infty} \int_0^{+\infty} \phi_1(y') \phi_2(z') e^{-\frac{y'^2}{2(t-s)}} \left( e^{-\frac{(t-s)^2}{2(t-s)}} - e^{-\frac{(t-s+y')^2}{2(t-s)}} \right) dy' dz'.$$

Therefore, it follows from (20) and (21) that

$$\lim_{n \to +\infty} \mathbb{E} \left[ \phi_1 \left( \frac{X([ns])}{\sigma \sqrt{n}} \right) \phi_2 \left( \frac{X([nt])}{\sigma \sqrt{n}} \right) \right] = \mathbb{E} [\phi_1(|B_s|) \phi_2(|B_t|)].$$

Using a similar estimate as the one in [17], we get

$$\lim_{n \to +\infty} \mathbb{E} [\phi_1 (X_n(s)) \phi_2 (X_n(t))] = \mathbb{E} [\phi_1(|B_s|) \phi_2(|B_t|)].$$

17
which concludes the convergence of \((Y_n)\) in two-dimensional marginal distribution to a reflected Brownian motion.

### 4.3 Tightness

Recall that the modulus of continuity of a function \(f : [0, 1] \to \mathbb{R}\) is defined by

\[
w_f(\delta) = \sup_{t,s \in [0,1],|t-s| < \delta} |f(t) - f(s)|.
\]

It is clear that \(w_X(\delta) \leq w_S(\delta)\). Using Theorem 7.3 in \([3]\), the tightness of \(X\) follows directly from the one of the classical random walk \((S(n))_{n \geq 0}\). We achieve the proof of Theorem 7.1 in \([3]\).

### 5 Auxiliary proofs

#### Proof of Lemma 4.2

By setting \(h_n(y) = \sqrt{n}P_y[r_1 > n]\), the Markov property yields

\[
\tilde{\Sigma}_n(x, t, s) = n \sum_{l \geq 0} \mathbb{E}_x \left[ \mathbb{P}_{X(r_l)}[r_1 \circ \theta^{r_l} > [nt] - [ns]; r_l = [ns]] \right]
\]

\[
= \frac{\sqrt{n}}{\sqrt{|nt - [ns]|}} \sum_{l \geq 0} \mathbb{E}_x \left[ h_{[nt]-[ns]}(X(r_l)); r_l = [ns] \right]
\]

\[
= \frac{1 + o(n)}{\sqrt{s(t - s)}} \sqrt{|ns|} T_{[ns]}(h_{[nt]-[ns]})(x).
\]

Let us prove that \(\sqrt{|ns|} T_{[ns]}(h_{[nt]-[ns]})(x) \to \frac{1}{\pi} \) as \(n \to +\infty\). Indeed,

\[
\left| \sqrt{|ns|} T_{[ns]}(h_{[nt]-[ns]})(x) - \frac{1}{\pi} \right| \leq B_1(n) + B_2(n),
\]

with

\[
B_1(n) = \left| \sqrt{|ns|} T_{[ns]}(h_{[nt]-[ns]})(x) - \frac{1}{\pi \nu(h)} \nu(h_{[nt]-[ns]}) \right| \quad \text{and} \quad B_2(n) = \frac{1}{\pi \nu(h)} |\nu(h_{[nt]-[ns]}) - \nu(h)|.
\]

By Lemma 2.1, it holds \(0 \leq h_n(y) \leq C_1 h(y)\), with \(h(y) = O(y)\), so that the sequence \((h_n)_{n \geq 1}\) is bounded in \(B_\alpha\). Thus, Corollary 3.5 yields

\[
B_1(n) \leq (1 + x) \left| \sqrt{|ns|} T_{[ns]} - \frac{1}{\pi \nu(h)} \right| \left| h_{[nt]-[ns]} \right|_{\alpha} \to 0 \quad \text{as} \quad n \to +\infty.
\]

Similarly, by Lemma 2.1 and the dominated convergence theorem,

\[
\lim_{n \to +\infty} \left| \nu(h_{[nt]-[ns]}) - \nu(h) \right| = 0,
\]

so that \(B_2(n) \to 0\) as \(n \to +\infty\).

#### Proof of Lemma 4.4

By setting \(\tilde{h}_n(y) = n^{3/2}P_y[r_1 = n]\), the Markov property yields

\[
\tilde{\Sigma}_n(x, s, t) = n^2 \sum_{l \geq 0} \mathbb{E}_x \left[ \mathbb{P}_{X(r_l)}[r_1 \circ \theta^{r_l} = [nt] - [ns]; r_l = [ns]] \right]
\]

\[
= \frac{n^{3/2}}{((|nt| - |ns|)^{3/2})} \sqrt{n} \sum_{l \geq 0} \mathbb{E}_x \left[ \tilde{h}_{[nt]-[ns]}(X(r_l)); r_l = [ns] \right]
\]

\[
= \frac{1 + o(n)}{\sqrt{s(t - s)^{3/2}}} \sqrt{|ns|} T_{[ns]}(\tilde{h}_{[nt]-[ns]})(x).
\]
By Corollary 2.2, it holds $0 \leq \tilde{h}_n(y) \leq C_3 h(y)$, with $h(y) = O(y)$, so that the sequence $(\tilde{h}_n)_{n \geq 1}$ is bounded in $B_\alpha$. We conclude as above to prove Lemma 4.2.
