Abstract. Choosing the right selection rate is a long standing issue in evolutionary computation. In the continuous unconstrained case, we prove mathematically that $\mu = 1$ leads to a sub-optimal simple regret in the case of the sphere function. We provide a theoretically-based selection rate $\mu/\lambda$ that leads to better convergence rates. With our choice of selection rate, we get a provable regret of order $O(\lambda^{-1})$ which has to be compared with $O(\lambda^{-2/d})$ in the case where $\mu = 1$. We complete our study with experiments to confirm our theoretical claims.

1 Introduction

In evolutionary computation, the selected population size often depends linearly on the total population size, with a ratio between $1/4$ and $1/2$: 0.270 is proposed in [4], [9,5] suggest $1/4$ and $1/2$. However, some sources [7] recommend a lower value $1/7$. Experimental results in [15] and theory in [8] together suggest a ratio $\min(d, \lambda/4)$ with $d$ the dimension, i.e. keep a population size at most the dimension. [11] suggests to keep increasing $\mu$ besides that limit, but slowly enough so that that rule $\mu = \min(d, \lambda/4)$ would be still nearly optimal. Weighted recombination is common [1], but not with a clear gap when compared to truncation ratios [10], except in the case of large population size [16]. There is, overall, limited theory around the optimal choice of $\mu$ for optimization in the continuous setting. In the present paper, we focus on a simple case (sphere function and single epoch), but prove exact theorems. We point out that the single epoch case is important by itself - this is fully parallel optimization [13,12,1]. Experimental results with a publicly available platform confirm the approach.

2 Theory

We consider the case of a single batch of evaluated points. We generate $\lambda$ points according to some probability distribution. We then select the $\mu$ best and average them. The result is our approximation of the optimum. This is therefore an extreme case of evolutionary algorithm, with a single population; this is commonly used for e.g. hyperparameter search in machine learning [30], though in most cases with the simplest case $\mu = 1$. 
2.1 Outline

We consider the optimization of the simple function \( x \mapsto ||x - y||^2 \) for an unknown \( y \in B(0, r) \). In Section 2.2 we introduce notations. In Section 2.3 we analyze the case of random search uniformly in a ball of radius \( h \) centered on \( y \). We can, therefore, exploit the knowledge of the optimum’s position and assume that \( y = 0 \). We then extend the results to random search in a ball of radius \( r \) centered on 0, provided that \( r > ||y|| \) and show that results are essentially the same up to an exponentially decreasing term (Section 2.4).

2.2 Notations

We are interested in minimizing the function \( f : x \in \mathbb{R}^d \mapsto ||x||^2 \) for a fixed unknown \( y \in \mathbb{R}^d \). In parallel one-shot black box optimization, i.e. we sample \( \lambda \) points \( X_1, \ldots, X_\lambda \) from some distribution \( D \) and we search for \( x^* = \arg\min_x f(x) \). In the following we will study the sampling from \( B(0, r) \), the uniform distribution on the \( \ell^2 \)-ball of radius \( r \); w.l.o.g. \( B(y, r) \) will also denote the \( \ell^2 \)-ball centered in \( y \) and of radius \( r \).

We are interested in comparing the strategy “\( \mu \)-best” vs “1-best”. We denote \( X(1), \ldots, X(\lambda) \), the sorted values of \( X_i \), i.e. \( X(1) \leq \cdots \leq X(\lambda) \). The “\( \mu \)-best” strategy is to return \( \bar{X}(\mu) = \frac{1}{\mu} \sum_{i=1}^{\mu} X(i) \) as an estimate of the optimum and the “1-best” is to return \( X(1) \). We will hence compare:

\[
E_{X_1, \ldots, X_\lambda \sim B(0, r)}[f(\bar{X}(\mu))] \quad \text{and} \quad E_{X_1, \ldots, X_\lambda \sim B(0, r)}[f(X(1))].
\]

To prove this result, we will compute the value of \( E[f(\bar{X}(\mu))] \) for all \( \lambda \) and \( \mu \). The following lemma gives a simple way of computing the expectation of a function depending only on the norm of its argument.

**Lemma 2.** Let \( d \in \mathbb{N}^* \). Let \( X \) be drawn uniformly in \( B(0, r) \) the \( d \)-dimensional ball of radius \( r \). Then for any continuous measurable function \( g : \mathbb{R} \to \mathbb{R} \), we have

\[
E_{X \sim B(0, r)}[g(||X||)] = \frac{d}{r^d} \int_0^r g(\alpha) \alpha^{d-1} d\alpha.
\]

In particular, we have \( E_{X \sim B(0, r)}[||X||^2] = \frac{d}{d+2} r^2 \).

2.3 When the center of the distribution is also the optimum

In this section we assume that \( y = 0 \) (i.e. \( f(x) = ||x||^2 \)) and consider sampling in \( B(0, r) \subset \mathbb{R}^d \). In this simple case, we show that keeping the best \( \mu > 1 \) sampled points is asymptotically a better strategy than selecting a single best point. The choice of \( \mu \) will be discussed in Section 2.4.

**Theorem 1.** For all \( \lambda > \mu \geq 2 \) and \( d \geq 2 \), \( r > 0 \), for \( f(x) = ||x||^2 \),

\[
E_{X_1, \ldots, X_\lambda \sim B(0, r)}[f(\bar{X}(\mu))] < E_{X_1, \ldots, X_\lambda \sim B(0, r)}[f(X(1))].
\]
Proof. Let \( V(r, d) \) be the volume of a ball of radius \( r \) in \( \mathbb{R}^d \) and \( S(r, d) \) be the surface of a sphere of radius \( r \) in \( \mathbb{R}^d \). Then \( \forall r > 0, V(r, d) = \frac{\pi^{d/2}}{\Gamma(d/2 + 1)} r^d \) and \( S(r, d - 1) = \frac{2\pi^{d/2}}{\Gamma(d/2)} r^{d-1} \). Let \( g : \mathbb{R} \to \mathbb{R} \) be a continuous function. Then:

\[
\mathbb{E}_{X \sim B(0, r)} [g(\|X\|)] = \frac{1}{V(r, d)} \int_{x: \|x\| \leq r} g(\|x\|) dx
\]

\[
= \frac{1}{V(r, d)} \int_{\alpha=0}^r \int_{\theta: \|\theta\| = \alpha} g(\alpha) d\theta d\alpha
\]

\[
= \frac{1}{V(r, d)} \int_{\alpha=0}^r \frac{S(1, d - 1)}{V(r, d)} \int_{\alpha=0}^\alpha g(\alpha) S(\alpha, d - 1) d\alpha
\]

\[
= \frac{d}{r^d} \int_{\alpha=0}^r \alpha^2 \alpha^{d-1} d\alpha
\]

\[
= \frac{d}{r^d} \left[ \alpha^{d+2} \right]_{0}^{r} = \frac{d}{d + 2} r^2.
\]

We now use the precedent lemma to compute the expected regret of the average of the \( \mu \) best points conditionally to the value of \( f(X(\mu + 1)) \). The trick of the proof is that, conditionally to \( f(X(\mu + 1)) \), the order of \( X(1), ..., X(\mu) \) has no influence over the average. Computing the expected regret conditionally to \( f(X(\mu + 1)) \) thus becomes straightforward.

Lemma 3. For all \( d > 0, r^2 > h > 0 \) and \( \lambda > \mu \geq 1 \), for \( f(x) = \|x\|^2 \),

\[
\mathbb{E}_{X_1, ..., X_{\lambda} \sim B(y, r)} [f(\tilde{X}(\mu)) \mid f(X(\mu + 1)) = h] = \frac{h}{\mu} \frac{d}{d + 2}.
\]

Proof. Let us first compute \( \mathbb{E}_S [f(\tilde{X}(\mu)) \mid f(X(\mu + 1)) = h] \). Note that for any function \( g : \mathbb{R}^d \to \mathbb{R} \) and distribution \( D \), we have

\[
\mathbb{E}_{X_1, ..., X_{\lambda} \sim D} [g(\tilde{X}(\mu)) \mid f(X(\mu + 1)) = h] = \mathbb{E}_{X_1, ..., X_{\mu} \sim D} \left[ g \left( \frac{1}{\mu} \sum_{i=1}^{\mu} X_i \right) \mid X_1 \ldots X_{\mu} \in \{x : f(x) \leq h\} \right]
\]

\[
= \mathbb{E}_{X_1, ..., X_{\mu} \sim D_h} \left[ g \left( \frac{1}{\mu} \sum_{i=1}^{\mu} X_i \right) \right],
\]
where $D_h$ is the restriction of $D$ to the level set $\{x : f(x) \leq h\}$. In our setting, we have $D = B(0, r)$ and $D_h = B(0, \sqrt{h})$. Therefore,

$$
E_{X_1, \ldots, X_\lambda \sim B(0, r)} \left[ f(\bar{X}(\mu)) \mid f(X_{(\mu+1)}) = h \right] = E_{X_1, \ldots, X_\lambda \sim B(0, r)} \left[ ||\bar{X}(\mu)||^2 \mid f(X_{(\mu+1)}) = h \right] = E_{X_1, \ldots, X_\mu \sim B(0, \sqrt{h})} \left[ \frac{1}{\mu} \sum_{i=1}^{\mu} X_i^2 \right] = \frac{1}{\mu^2} \sum_{i,j=1, i \neq j}^{\mu} E_{X_1, \ldots, X_\mu \sim B(0, \sqrt{h})} [X_i^T X_j] + \frac{1}{\mu^2} \sum_{i=1}^{\mu} E_{X_i \sim B(0, \sqrt{h})} [||X_i||^2] = \frac{1}{\mu} E_{X \sim B(0, \sqrt{h})} [||X||^2].
$$

By Lemma 2, we have: $E_{X \sim B(0, \sqrt{h})} [||X||^2] = \frac{d}{\pi \frac{d}{2}} h$. Hence $E_{X_1, \ldots, X_\lambda \sim B(0, r)} \left[ f(\bar{X}(\mu)) \mid f(X_{(\mu+1)}) = h \right] = h \left( \frac{d+2}{d} \right) \Gamma(\mu + 1) / \Gamma(\mu + 1 + 2/d)$.

The result of Lemma 3 shows that $E \left[ f(\bar{X}(\mu)) \mid f(X_{(\mu+1)}) = h \right]$ depends linearly on $h$. We now establish a similar dependency for $E \left[ f(X_{(1)}) \mid f(X_{(\mu+1)}) = h \right]$.

**Lemma 4.** For $d > 0$, $h > 0$, $\lambda > \mu \geq 1$,

$$
E_{X_1, \ldots, X_\lambda \sim B(0, r)} \left[ f(X_{(1)}) \mid f(X_{(\mu+1)}) = h \right] = h \left( \frac{d+2}{d} \right) \Gamma(\mu + 1) / \Gamma(\mu + 1 + 2/d).
$$

**Proof.** First note that using the same argument as in Lemma 3 $\forall \beta > 0$:

$$
P_{X_1, \ldots, X_\lambda \sim B(0, r)} \left[ f(X_{(1)}) > \beta \mid f(X_{(\mu+1)}) = h \right] = P_{X_1, \ldots, X_\mu \sim B(0, \sqrt{h})} [f(X_1) > \beta, \ldots, f(X_\mu) > \beta] = P_{X \sim B(0, \sqrt{h})} [f(X) > \beta]^\mu.
$$

Recall that the volume of a $d$-dimensional ball of radius $r$ is proportional to $r^d$. Thus, in case $\beta < h$, we get:

$$
P_{X \sim B(0, \sqrt{h})} [f(X) < \beta] = \frac{\sqrt{\beta^d}}{\sqrt{h}} = \left( \frac{\beta}{h} \right)^{\frac{d}{2}}.
$$
It is known that for every positive random variable \(X\),
\[
\mathbb{E}(X) = \int_{0}^{\infty} \mathbb{P}(X > \beta) d\beta.
\]
Therefore:
\[
\mathbb{E}_S \left[ f \left( X_{(1)} \right) \mid f \left( X_{(\mu+1)} \right) = h \right] = \int_{0}^{h} \mathbb{P} \left[ f \left( X_{(1)} \right) > \beta \mid f \left( X_{(\mu+1)} \right) = h \right] d\beta
\]
\[
= \int_{0}^{h} \left( 1 - \left( \frac{\beta}{h} \right)^{\frac{1}{d}} \right)^{\mu} d\beta
\]
\[
= h \int_{0}^{1} \left( 1 - u^{\frac{1}{d}} \right)^{\mu} du
\]
\[
= h \frac{2}{d} \int_{0}^{1} (1 - t^{\frac{1}{d}})^{\mu} t^{2/d - 1} dt = h \frac{\Gamma \left( d + 2 \right) \Gamma (\mu + 1)}{\Gamma (\mu + 1 + 2/d)}.
\]
To obtain the last equality, we identify the integral with the beta function of parameters \(\mu + 1\) and \(\frac{2}{d}\).

We now directly compute \(\mathbb{E}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( X_{(1)} \right) \right] \).

**Lemma 5.** For all \(d > 0\), \(\lambda > 0\) and \(r > 0\):
\[
\mathbb{E}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( X_{(1)} \right) \right] = r^2 \frac{\Gamma \left( \frac{d + 2}{d} \right) \Gamma (\lambda + 1)}{\Gamma (\lambda + 1 + 2/d)}.
\]

**Proof.** As in Lemma 4 we have:
\[
\mathbb{P}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( X_{(1)} \right) > \beta \right] = \mathbb{P}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( X_1 \right) > \beta, \ldots, f \left( X_{\lambda} \right) > \beta \right]
\]
\[
= \mathbb{P}_{X \sim B(0, r)} \left[ f \left( X \right) > \beta \right]^\lambda
\]
\[
= \left( \frac{\sqrt{\beta}}{r} \right)^d.
\]
The result then follows by reasoning as in the proof of Lemma 4.

By combining the results above, we obtain the exact formula for \(\mathbb{E} \left[ f \left( \bar{X}_{(\mu)} \right) \right] \).

**Theorem 6.** For all \(d, 0 \leq \mu < \lambda, r\):
\[
\mathbb{E}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( \bar{X}_{(\mu)} \right) \right] = \frac{r^2 d \times \Gamma (\lambda + 1) \Gamma (\mu + 1 + 2/d)}{\mu (d + 2) \Gamma (\mu + 1) \Gamma (\lambda + 1 + 2/d)}.
\]

**Proof.**
\[
\mathbb{E}_{X_1, \ldots, X_{\lambda} \sim B(0, r)} \left[ f \left( \bar{X}_{(\mu)} \right) \right] = \mathbb{E} \left[ \mathbb{E} \left[ f \left( \bar{X}_{(\mu)} \right) \mid f \left( X_{(\mu+1)} \right) \right] \right]
\]
\[
= \frac{d}{\mu d + 2} \mathbb{E} \left[ f \left( X_{(\mu+1)} \right) \right]
\]
\[
= \frac{d}{\mu d + 2} \frac{\Gamma (\mu + 1 + 2/d)}{\Gamma (\mu + 1)} \mathbb{E} \left[ f \left( X_{(1)} \right) \mid f \left( X_{(\mu+1)} \right) \right]
\]
\[
= \frac{d}{\mu d + 2} \frac{\Gamma (\mu + 1 + 2/d)}{\Gamma (\mu + 1)} \mathbb{E} \left[ f \left( X_{(1)} \right) \right]
\]
\[
= \frac{r^2 d \times \Gamma (\lambda + 1) \Gamma (\mu + 1 + 2/d)}{\mu (d + 2) \Gamma (\mu + 1) \Gamma (\lambda + 1 + 2/d)}.
\]
We have Proof.

Let Lemma 8. Consider Theorem 9. That the function \( f \) \( B \) are the same. We now assume that we sample from the distribution so far we treated the case where the center of the distribution and the optimum (see Figure 1). We can deduce asymptotic convergence rates:

**Corollary 7.** Consider \( d > 0 \). When \( \lambda \to \infty \), we have

\[
E_{X_1, \ldots, X_d \sim B(0,r)} \left[ f(X_{(1)}) - \bar{X} \right] \sim \lambda^{-\frac{d+2}{2}} r^2 \sqrt{2} d \left( \frac{\lambda}{\mu} \right)^{\frac{d+2}{2} - 1}.
\]

As a result, \( \forall c \in (0,1) \), \( E \left( f(X_{(1)}) \right) \in \Theta \left( \frac{1}{\lambda} \right) \) and \( E \left( f(X_{(1)}) \right) \in \Theta \left( \frac{1}{\lambda^2} \right) \).

**Proof.** We recall the Stirling equivalent formula for the gamma function: when \( z \to \infty \),

\[
\Gamma(z) = \sqrt{2\pi} \left( \frac{z}{e} \right)^z \left( 1 + O \left( \frac{1}{z} \right) \right).
\]

Using this approximation, we get the expected results. \( \square \)

### 2.4 Convergence when the sampling is not centered on the optimum

So far we treated the case where the center of the distribution and the optimum are the same. We now assume that we sample from the distribution \( B(0, r) \) and that the function \( f \) is \( f(x) = ||x - y||^2 \) with \( ||y|| \leq r \). We define \( \epsilon = \frac{||y||}{r} \).

**Lemma 8.** Let \( r > 0 \), \( d > 0 \), \( \lambda > \mu \geq 1 \), we have:

\[
P_{X_1, \ldots, X_d \sim B(0,r)} (f(X_{(1)}) > (1 - \epsilon)^2 r^2) = P_{U \sim B(\lambda, (1-\epsilon)^2)} (U \leq \mu),
\]

where \( B(\lambda, p) \) is a binomial law of parameters \( \lambda \) and \( p \).

**Proof.** We have \( f(X_{(1)}) > (1 - \epsilon)^2 r \iff \sum_{i=1}^{\lambda} I_{\{f(X_i) \leq (1 - \epsilon)^2 r^2\}} \leq \mu \) since \( I_{\{f(X_i) \leq (1 - \epsilon)^2 r^2\}} \) are independent Bernoulli variables of parameter \( (1 - \epsilon)^2 \), hence the result. \( \square \)

Using Lemma 8, we now get lower and upper bounds on \( E \left[ f \left( X_{(1)} \right) \right] \):

**Theorem 9.** Consider \( d > 0 \), \( r > 0 \), \( \lambda > \mu > 0 \). The expected value of \( f(\bar{X}_{(1)}) \) satisfies both

\[
E_{X_1, \ldots, X_d \sim B(0,r)} \left[ f(\bar{X}_{(1)}) \right] \leq 4r^2 P_{U \sim B(\lambda, (1-\epsilon)^2)} (U \leq \mu) + \frac{r^2 d \times \Gamma(\lambda + 1) \Gamma(\mu + 2/d)}{\mu(d+2) \Gamma(\mu + 1) \Gamma(\lambda + 1 + 2/d)}
\]

and

\[
E_{X_1, \ldots, X_d \sim B(0,r)} \left[ f(\bar{X}_{(1)}) \right] \geq \frac{r^2 d \times \Gamma(\lambda + 1) \Gamma(\mu + 2/d)}{\mu(d+2) \Gamma(\mu + 1) \Gamma(\lambda + 1 + 2/d)}.
\]
Theorem 10. Consider the optimum. If we consider the problem a more precise asymptotic result for the choice of $\mu$ proving that the $\lambda$ attained for the $\mu$ on the optimum, previous section). Bound the centered case (i.e. when the distribution is centered combining these equations yields the first (upper) bound. The second (lower) bound is deduced from the centered case (i.e. when the distribution is centered on the optimum, previous section).

Figure 2 gives an illustration of the bounds. Until $\mu \simeq (1 - \epsilon)^d \lambda$, the centered and non centered case coincide when $\lambda \to \infty$: therefore, in this case, we can have a more precise asymptotic result for the choice of $\mu$.

Theorem 10. Consider $d > 0$, $r > 0$ and $y \in \mathbb{R}^d$. Let $\epsilon = \|y\| \in [0, 1)$ and $f(x) = \|x - y\|^2$. When using $\mu = [c \lambda]$ with $0 < c < (1 - \epsilon)^d$, we get as $\lambda \to \infty$, for a fixed $d$,

$$
\mathbb{E}_{X_1, \ldots, X_d \sim \mathcal{B}(0, r)} [f(\tilde{X}(\mu))] = \frac{dr^2c^{2/d - 1}}{(d + 2)\lambda} + o\left(\frac{1}{\lambda}\right).
$$

Proof. Let $\mu_\lambda = [c \lambda]$ with $0 < c < (1 - \epsilon)^d$. We immediately have from Hoeffding’s concentration inequality:

$$
\mathbb{P}(U \sim \mathcal{B}(\lambda, (1 - \epsilon)^d)) (U \leq \mu_\lambda) \in o\left(\frac{1}{\lambda}\right)
$$

when $\lambda \to \infty$. From Corollary 7, we also get:

$$
\frac{r^2d \times \Gamma(\lambda + 1) \Gamma(\mu + 1 + 2/d)}{\mu(d + 2) \Gamma(\mu + 1) \Gamma(\lambda + 1 + 2/d)} \sim \frac{dr^2c^{2/d - 1}}{(d + 2)\lambda}.
$$

Using the inequalities of Theorem 9 we obtain the desired result.

The result of Theorem 10 shows that a convergence rate $O(\lambda^{-1})$ can be attained for the $\mu$-best approach with $\mu > 1$. The rate for $\mu = 1$ is $\Theta(\lambda^{-2/d})$, proving that the $\mu$-best approach leads asymptotically to a better estimation of the optimum. If we consider the problem

$$
\min_{\mu} \max_{y : ||y|| \leq r} \mathbb{E} [f_y(\tilde{X}(\mu))]
$$

with $f_y$ the objective function $x \mapsto ||x - y||^2$, then $\mu = [c \lambda]$ with $0 < c < (1 - \epsilon)^d$ achieves the $O(\lambda^{-1})$ convergence rate.

All the results we proved in this section are easily extendable to strongly convex quadratic functions. For larger class of functions, it is less immediate, and left as future work.
2.5 Using quasi-convexity

The method above was designed for the sphere function, yet its adaptation to other quadratic convex functions is straightforward. On the other hand, our reasoning might break down when applied to multimodal functions. We thus consider an adaptive strategy to define \( \mu \). A desirable property to a \( \mu \)-best approach is that the level-sets of the functions are convex. A simple workaround is to choose \( \mu \) maximal such that there is a quasiconvex function which is identical to \( f \) on \( \{X(1), \ldots, X(\mu)\} \). If the objective function is quasi-convex on the convex hull of \( \{X(1), \ldots, X(\tilde{\mu})\} \) with \( \tilde{\mu} \leq \lambda \), then:

- for any \( i \leq \tilde{\mu} \), \( X(i) \) is on the frontier (denoted \( \partial \)) of the convex hull of \( \{X(1), \ldots, X(i)\} \).
- Thus, the value

\[
h = \max \{i \in [1, \lambda], \forall j \leq i, X(j) \in \partial \{\text{ConvexHull}(X(1), \ldots, X(j))\}\}
\]

verifies \( h \geq \tilde{\mu} \) so that \( \mu = \min(h, \tilde{\mu}) \) is actually equal to \( \tilde{\mu} \).

As a result:

- in the case of the sphere function, or any quasi-convex function, if we set \( \tilde{\mu} = \lfloor \lambda (1 - \epsilon) d \rfloor \), using \( \mu = \min(h, \tilde{\mu}) \) leads to the same value of \( \mu = \tilde{\mu} = \lfloor \lambda (1 - \epsilon) d \rfloor \). In particular, we preserve the theoretical guarantees of the previous sections for the sphere function \( x \mapsto ||x - y||^2 \).
- if the objective function is not quasi-convex, we can still compute the quantity \( h \) defined above, but we might get a \( \mu \) smaller than \( \tilde{\mu} \), but intuitively it prevents from keeping to many points when the function is “highly” non quasiconvex.

3 Experiments

To validate our theoretical findings, we first compare the formulas obtained in Theorems 6 and 9 with their empirical estimates. We then perform larger scale experiments in a one-shot optimization setting.
3.1 Experimental validation of theoretical formulas

Figure 1 compares the theoretical formula from Theorem 6 and its empirical estimation: we note that the results coincide and validate our formula. Moreover, the plot confirms that taking the $\mu$-best points leads to a lower regret than the 1-best approach.

We also compare in Figure 2 the theoretical bounds from Theorem 9 with their empirical estimates. We remark that for $\mu \leq (1 - \epsilon)d\lambda$ the convergence of the two bounds to $\mathbb{E}(f(\hat{X}(\mu)))$ is fast. There exists a transition phase around $\mu \simeq (1 - \epsilon)d\lambda$ on which the regret is reaching a minimum: thus, one needs to choose $\mu$ both small enough to reduce bias and large enough to reduce variance. We compared to other empirically estimated values for $\mu$ from [4,9,5]. It turns out that if the population is large, our formula for $\mu$ leads to a smaller regret. Our strategy also assumes the knowledge of $\epsilon$ which is not the case in practice. It is interesting to note that if the center of the distribution and the optimum are close (i.e. $\epsilon$ is small), one can choose a larger $\mu$ to get a lower variance on the estimator of the optimum.

3.2 One-shot optimization in Nevergrad

In this section we test different formulas and variants for the choice of $\mu$ for a larger scale of experiments in the one-shot setting. Equations 11-16 present the...
different formulas for $\mu$ used in our comparison.

$$\mu = 1 \quad \text{No prefix (1)}$$

$$\mu = \text{clip} \left(1, d, \frac{\lambda}{4}\right) \quad \text{Prefix: Avg (averaging)} \quad (2)$$

$$\mu = \text{clip} \left(1, \infty, \frac{\lambda}{1.1^d}\right) \quad \text{Prefix: EAvg (Exp. Averaging)} \quad (3)$$

$$\mu = \text{clip} \left(1, \min \left(h, \frac{\lambda}{4}\right), d + \frac{\lambda}{1.1^d}\right) \quad \text{Prefix: HCHAvg (h from Convex Hull)} \quad (4)$$

$$\mu = \text{clip} \left(1, \infty, \frac{\lambda}{1.01^d}\right) \quad \text{Prefix: TEAvg (Tuned Exp. Averaging)} \quad (5)$$

$$\mu = \text{clip} \left(1, \min \left(h, \frac{\lambda}{4}\right), d + \frac{\lambda}{1.01^d}\right) \quad \text{Prefix: THCHAvg (Tuned HCH Avg)} \quad (6)$$

where $\text{clip}(a, b, c) = \max(a, \min(b, c))$ is the projection of $c$ in $[a, b]$ and $h$ is the maximum $i$ such that, for all $j \leq i$, $X(j)$ is on the frontier of the convex hull of $\{X(1), \ldots, X(j)\}$ (Sect. 2.5). Equation (1) is the naive recommendation “pick up the best so far”. Equation (2) existed before the present work: it was, until now, the best rule [15] , overall, in the Nevergrad platform. Equations (3) and (5) are the proposals we deduced from Theorem 10 asymptotically on the sphere, they should have a better rate than Equation (1). Equations (2) and (4) are counterparts of Equations (3) and (5) that combine the latter formulas with ideas from [15]. Theorem 10 remains true if we add to $\mu$ some constant depending on $d$ so we fine tune our theoretical equation (Eq. 3) with the one provided by [15], so that...
Fig. 4. Experimental curves comparing various methods for choosing $\mu$ as a function of $\lambda$ in dimension 25 (Fig. 3 continued for dimension 25; see Fig. 5 for dimension 200). Our proposals lead to good results but we notice that they are outperformed by $\text{TEAvg}$ and $\text{EAvg}$ for Rastrigin: it is better to not take into account non quasiconvexities because the overall shape is more meaningful that local ruggedness. This phenomenon does not happen for the more rugged HM (Highly Multimodal) function. It also does not happen in dimension 3 or dimension 200 (previous and next figures): in those cases, THCH performed best. Confidence intervals shown in lighter color (they are quite small, and therefore they are difficult to notice).

$\mu$ is close to the value in Eq. 2 for moderate values of $\lambda$. We perform experiments in the open source platform Nevergrad [14].

While previous experiments (Figures 1 and 2) were performed in a controlled ad hoc environment, we work here with more realistic conditions:

- The sampling is Gaussian (i.e. not uniform in a ball),
- The objective functions are not all sphere-like,
- Budgets vary but are not asymptotic.

Figures 3, 4, 5 present our results in dimension 3, 25 and 200 respectively. The objective functions are randomly translated using $\mathcal{N}(0,0.2L_d)$. The objective functions are defined as $f_{\text{Sphere}}(x) = ||x||^2$, $f_{\text{Cigar}}(x) = 10^6 \sum_{i=2}^{d} x_i^2 + x_1^2$, $f_{\text{HM}}(x) = \sum_{i=1}^{d} x_i^2 \times (1.1 + \cos(1/x_i))$, $f_{\text{Rastrigin}}(x) = 10d + f_{\text{Sphere}}(x) - 10 \sum_{i=1}^{d} \cos(2\pi x_i)$.

Our proposed equations $\text{TEAvg}$ and $\text{EAvg}$ are unstable: they sometimes perform excellently (e.g. everything in dimension 25, Figure 4), but they can also fail dramatically (e.g. dimension 3, Figure 3). Our combinations $\text{THCHAvg}$ and $\text{HCHAvg}$ perform well: in most settings, $\text{THCHAvg}$ performs best. But the gap with the previously proposed $\text{Avg}$ is not that big. The use of quasiconvexity as described in Section 2.5 was usually beneficial: however, in dimension 25 for the Rastrigin function, it prevented the averaging from benefiting from the overall “approxi-
Fig. 5. Experimental curves comparing various methods for choosing $\mu$ as a function of $\lambda$ in dimension 200 (Figures 3 and 4, continued for dimension 200). Confidence intervals shown in lighter color (they are quite small, and therefore they are difficult to notice). Our proposed methods \textsc{THCHAvg} and \textsc{HCHAvg} perform well overall.

...mate” convexity of Rastrigin. This phenomenon did not happen for the “more” multimodal function HM, or in other dimensions for the Rastrigin function.

4 Conclusion

We have proved formally that the average of the $\mu$ best is better than the single best in the case of the sphere function (simple regret $O(1/\lambda)$ instead of $O(1/\lambda^2/d)$) with uniform sampling. We suggested a value $\mu = \lfloor c \lambda \rfloor$ with $0 < c < (1 - \epsilon)^d$. Even better results can be obtained in practice using quasiconvexity, without losing the theoretical guarantees of the convex case on the sphere function. Our results have been successfully implemented in \cite{14}. The improvement compared to the state of the art, albeit moderate, is obtained without any computational overhead in our method, and supported by a theoretical result.

\textbf{Further work.} Our theorem is limited to a single iteration, i.e. fully parallel optimization, and to the sphere function and experiments are positive in the convex case: we need extensions of the theory. Our experimental methods include an automatic choice of $\mu$ in the multimodal case using quasiconvexity, for which the theoretical analysis has yet to be fully developed - we show that this is not detrimental in the convex setting, but not that it performs better in a non-convex setting.
