Abstract: We propose a supersymmetric extension of the anomaly-free and three families nonuniversal $U(1)$ model, with the inclusion of four Higgs doublets and four Higgs singlets. The quark sector is extended by adding three exotic quark singlets, while the lepton sector includes two exotic charged lepton singlets, three right-handed neutrinos and three sterile Majorana neutrinos to obtain the fermionic mass spectrum. By implementing an additional $Z_2$ symmetry, the Yukawa coupling terms are suited in such a way that the fermion mass hierarchy is obtained without fine-tuning. The effective mass matrix for SM neutrinos is fitted to current neutrino oscillation data to check the consistency of the model with experimental evidence, obtaining that the normal-ordering scheme is preferred over the inverse ones. The electron and up, down and strange quarks are massless at tree level, but they get masses through radiative correction at one loop level coming from the sleptons and Higgsinos contributions. We show that the model predicts a like-Higgs SM mass at electroweak scale by using the VEV according to the symmetry breaking and fermion masses.

Talk presented at the 2019 Meeting of the Division of Particles and Fields of the American Physical Society (DPF2019), July 29–August 2, 2019, Northeastern University, Boston, C1907293.

1 Introduction

A $U(1)_X$ extension of the Minimal Supersymmetric Standard Model is built and explored by considering a non-universal $X$ charge assignment that makes the model anomaly free with the inclusion of additional quarks, leptons, Higgs doublets and singlets. The standard model fermion sector is examined and provides neutrino masses through a see saw mechanism ensuring the correct squared mass differences and the correct CKM and PMNS mixing matrices because a previous work result. Furthermore, 3 fermions become massless but acquire a finite mass value through radiative corrections thanks to the coupling to a scalar Higgs singlet which does not acquire a VEV. The scalar sector is explored and it is found the conditions for having the lightest of them as a 125 GeV CP-even Higgs boson which depends only on the GeV VEV. Meanwhile the other mass eigenstates lies in the Tev Scale; as well for the charged and CP-odd higgs bosons.

2 Scalar sector

The Lagrangian for the scalar sector that describes the minimal supersymmetric extension to the $U(1)_X$ model in the literature is given by the addition of F-terms, D-terms and a soft-supersymmetry breaking potential. The F-terms were obtained from the following superpotential:

$$W = -\mu_1 \Phi_1' \Phi_1 - \mu_2 \Phi_2' \Phi_2 - \mu_{\chi} \chi' \chi' - \mu_{\sigma} \sigma' \sigma'.$$

Therefore, the F-terms’ potential for scalar fields is given by

$$-V_F = \mu_1^2 (\Phi_1' \Phi_1 + \Phi_1'^* \Phi_1) + \mu_2^2 (\Phi_2' \Phi_2 + \Phi_2'^* \Phi_2') + \mu_{\chi}^2 (\chi' \chi + \chi'^* \chi') + \mu_{\sigma}^2 (\sigma' \sigma + \sigma'^* \sigma').$$
Table 1: Scalar content of the model, non-universal $X$ quantum number, $Z_2$ parity and hypercharge

| Higgs Scalar Doublets | $X^\pm$ | $Y$ | Higgs Scalar Singlets | $X^\pm$ | $Y$ |
|-----------------------|--------|----|-----------------------|--------|----|
| $\hat{\phi}_1 = \begin{pmatrix} \phi_1^+ \\ \phi_1^- \end{pmatrix} \sqrt{2}$ | $+2/3^+$ | $+1$ | $\hat{\chi} = \frac{\tilde{\chi}_x + v_x + i\tilde{\chi}_y}{\sqrt{2}}$ | $+1/3^+$ | $0$ |
| $\hat{\phi}_2 = \begin{pmatrix} \phi_2^+ \\ \phi_2^- \end{pmatrix} \sqrt{2}$ | $+1/3^-$ | $+1$ | $\hat{\sigma} = -\frac{\sigma_1 v_1 + i\sigma_2 v_2}{\sqrt{2}}$ | $-1/3^-$ | $0$ |
| $\hat{\phi}_1' = \begin{pmatrix} \phi_1'^+ \\ \phi_1'^- \end{pmatrix} \sqrt{2}$ | $-2/3^+$ | $-1$ | $\hat{\chi}' = \frac{\chi_x' + v_x' + i\chi_y'}{\sqrt{2}}$ | $-1/3^+$ | $0$ |
| $\hat{\phi}_2' = \begin{pmatrix} \phi_2'^+ \\ \phi_2'^- \end{pmatrix} \sqrt{2}$ | $-1/3^-$ | $-1$ | $\hat{\sigma}' = \frac{\sigma_1 v_1' + i\sigma_2 v_2'}{\sqrt{2}}$ | $+1/3^-$ | $0$ |

On the other hand, the D-terms potential, consequence of gauge invariance, reads:

$$-V_D = \frac{g'^2}{2} [ |\Phi_1^i \Phi_2^j|^2 + |\Phi_1'^i \Phi_2'^j|^2 + |\Phi_1^i \Phi_1'^j|^2 + |\Phi_1'^i \Phi_2|^2 + |\Phi_2'^i \Phi_2|^2 - |\Phi_1|^2 |\Phi_2|^2$$

$$- |\Phi_1'^i|^2 |\Phi_2'^j|^2 + \frac{g'^2 + g^2}{8}(\Phi_1^i \Phi_1 + \Phi_2^i \Phi_2 - \Phi_1'^i \Phi_1' - \Phi_2'^i \Phi_2')^2$$

$$+ \frac{g^2}{2} \left[ \frac{2}{3} (\Phi_1^i \Phi_1 - \Phi_1'^i \Phi_1') + \frac{1}{3} (\Phi_2^i \Phi_2 - \Phi_2'^i \Phi_2') - \frac{1}{3} (\sigma^* \sigma - \sigma'^* \sigma') \right]^2$$

Finally, the soft supersymmetry breaking Lagrangian turns out to be:

$$-V_{soft} = m_1^2 \Phi_1^i \Phi_1 + m_2^2 \Phi_2^i \Phi_2 + m_3^2 \chi^i \chi + M_0^2 \Phi_1^i \Phi_1'^j + m_4^2 \Phi_2^i \Phi_2'^j + m_5^2 \chi^i \chi' + m_6^2 \sigma^i \sigma + m_7^2 \sigma^i \sigma'$$

$$+ m_8^2 \chi^i \chi'$$

$$+ \frac{2\sqrt{2}}{9} (-k_1 \phi_1 \phi_2 \chi' + k_2 \phi_1 \phi_2 \chi - k_3 \phi_1' \phi_2' \chi + k_4 \phi_1' \phi_2' \chi') + h.c.$$  

(4)

2.1 CP-Even scalar particles

After symmetry breaking all Higgs doublets and singlets acquire a VEV which allows us to construct the following a squared mass matrix for CP-Even scalar particles

$$\frac{1}{2} M_h^2 = \begin{pmatrix} M_\phi & M_\phi \chi \\ M_\phi^T & M_{\chi \chi} \end{pmatrix},$$

$$M_\phi =$$

$$\begin{pmatrix}
-f_4 g v_1^2 - \frac{v_2 f_{1i}}{g y_1} - \frac{v_1^i v_1^j}{2 v_1^2} & -f_4 g v_1 v_1^j - \frac{v_1^j v_2}{2 v_1^2} & f_2 g v_1 v_2 + \frac{f_{1k}}{g} & -f_2 g v_1 v_2' \\
* & f_4 g v_1^2 + \frac{v_1^j v_2}{2 v_1^2} + \frac{v_1^2 v_1^j}{2 v_1^2} & -f_2 g v_1 v_2' & f_2 g v_1 v_2' + \frac{f_{1k}}{g} \\
* & * & f_4 g v_2^2 - \frac{v_2 f_{1k}}{g y_2} - \frac{v_1^j v_2}{2 v_2^2} & -f_1 g v_2 v_2' - \frac{\mu_2^2}{2 v_2^2} \\
* & * & * & f_1 g v_2^2 - \frac{v_2 f_{1k}}{g y_2} - \frac{v_2 v_2^j}{2 v_2^2}
\end{pmatrix}.$$
As a consequence of the inclusion of the symmetry $U(1)_X$, a new gauge boson $Z'$ is predicted, and it has to be included in the covariant derivative.

$$D_\mu = \partial_\mu - ig W_\mu^a T_a - ig Y^a \frac{Y}{2} B_\mu - ig X Z'_\mu$$

Therefore the gauge boson masses are determined by the interaction terms, which are present in the scalar field kinetic terms. On one hand the charged bosons $W_\mu^\pm = (W_\mu^1 \pm W_\mu^2)/\sqrt{2}$ acquire masses...
When adopting the definitions (10-12). Thus, in the gauge boson sector we can split in two the matrix after SSB given by:

\[
M_0^2 = \frac{1}{4} \begin{pmatrix}
g^2 v^2 & -gg'v^2 & -\frac{2}{3}g g \chi v^2 (1 + \cos^2 \beta) \\
* & g^2 v^2 & \frac{2}{3} g g \chi v^2 (1 + \cos^2 \beta) \\
* & * & \frac{4}{9} g g \chi v^2 \left[ 1 + \left( 1 + 3 \cos^2 \beta \right) \frac{v^2}{v_X^2} \right]
\end{pmatrix},
\]

where we have defined:

\[
v^2 = v_1^2 + v_2^2 + v_1'^2 + v_2'^2 = (246.22 GeV)^2
\]

\[
\tan \beta = \sqrt{\frac{v_2^2 + v_2'^2}{v_1^2 + v_1'^2}} \equiv \frac{V_2}{V_1}
\]

\[
V_X^2 \equiv v_X^2 + v_\chi^2
\]

Despite this model we have 4 Higgs doubles, it recreates the same mass structure found in [1] when adopting the definitions [10][12]. Thus, in the gauge boson sector we can split in two the acceptable parameter values given in the same reference in order to know the possible values for doublets VEV. Nevertheless, it also means that the neutral boson mass eigenvalues are already determined.

\[
M_\gamma = 0 \quad M_Z \approx \frac{g v}{2 \cos \theta_W} \quad M_{Z'} \approx \frac{g_X V_X}{3}, \quad (13)
\]

where \(\tan \theta_W = \frac{g'}{g}\), as it is defined in the standard model. Also, the PMNS matrices [2], [3] are reproduced since in the no-SUSY version of the theory guarantees it.

### 3 Fermion sector

#### 3.1 Quark masses

According to the \(SU(2)_L \otimes U(1)_Y \otimes U(1)_X \otimes Z_2\) symmetry, the most general superpotential for the quarks superfields is given by:

\[
W_Q = q_1 \hat{\Phi}_1 h_{1L}^2 (U_1^2)^C + q_1 \hat{\Phi}_1 h_{1L}^2 (U_1^2)^C + q_3 \hat{\Phi}_1 h_{1L}^{3k} (U_1^2)^C - q_1 \hat{\Phi}_1 h_{2L}^{3k} (U_1^2)^C + q_3 \hat{\Phi}_1 h_{2L}^{3k} (U_1^2)^C + q_1 \hat{\Phi}_1 h_{2L}^{11} \tilde{T}_L^C \\
+ q_3 \hat{\Phi}_1 h_{11}^{11} \tilde{T}_L^C - q_1 \hat{\Phi}_1 h_{11}^{11} (j_1^2)^C - q_3 \hat{\Phi}_1 h_{2L}^{22} (j_1^2)^C + \tilde{T}_L^C \hat{\Phi}_1 h_{2L}^{22} (j_1^2)^C + \tilde{T}_L^C \hat{\Phi}_1 h_{2L}^{22} (j_1^2)^C + \tilde{T}_L^C \hat{\Phi}_1 h_{2L}^{22} (j_1^2)^C,
\]

where \(q_1 = q_2 = q_3\), and \(i = 1, 2\) while the mixing matrix between exotic particles turns out to depend on the singlet VEV \(v_X, v_X'\). In this way a seesaw mechanism can be implemented, in such a way that the rotated mass matrices can be read as follows:

\[
\begin{align*}
\mathbf{m}_U^2 &= \left(V_{L}^{(U)}\right)^T M_{eR}^2 V_L^{(U)} = \begin{pmatrix} m_{T_1}^2 & 0 \\ 0 & m_{T_2}^2 \end{pmatrix}, \\
m_{T_1}^2 &\approx \frac{1}{2} \begin{pmatrix} v_1^2 + v_2^2 + v_1'^2 + v_2'^2 \\ v_1 v_2 + v_1'^2 + v_2'^2 \\ v_1 v_2 + v_1'^2 + v_2'^2 \end{pmatrix}, \\
m_{T_2}^2 &\approx \frac{1}{2} v_\chi^2 (c_\chi^2 + h_\chi^2)
\end{align*}
\]

\[
\begin{align*}
\mathbf{m}_D^2 &= \left(V_{L}^{(D)}\right)^T M_{eR}^2 V_L^{(D)} = \begin{pmatrix} m_{D_1}^2 & 0 \\ 0 & m_{D_2}^2 \end{pmatrix}, \\
m_{D_1}^2 &\approx \frac{1}{2} \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \\
m_{D_2}^2 &\approx \frac{1}{2} \begin{pmatrix} v_2^2 (B_{31}^2 + B_{32}^2 + B_{33}^2) \end{pmatrix}, \\
m_{D}^2 &\approx \frac{1}{2} \begin{pmatrix} k_{11}^2 & 0 \\ 0 & k_{22}^2 \end{pmatrix}.
\end{align*}
\]
Analogously, the lepton superpotencial correspond to the non-SUSY potential; with the fields

\[ W_L = \hat{\bar{\nu}}_{L}^{\mu} \bar{h}_{2e}^{\mu}(\bar{\nu}_{L}^{C})^C + \hat{\bar{\nu}}_{L}^{\mu} \bar{h}_{2e}^{\mu}(\bar{\nu}_{L}^{C})^C + \hat{\bar{\nu}}_{L}^{\mu} \bar{h}_{2e}^{\mu}(\bar{\nu}_{L}^{C})^C + \hat{\bar{\nu}}_{L}^{\mu} \bar{h}_{1E}^{\mu}(\bar{\nu}_{L}^{C})^C + \hat{\bar{\nu}}_{L}^{\mu} \bar{h}_{1E}^{\mu}(\bar{\nu}_{L}^{C})^C \]

In a similar way, the conditions for implementing a seesaw mechanism are given in the matrix structure. In this case the lightest fermion, identified as the electron, turns out to be massless but it acquire a finite mass value through radiative corrections due to the interaction with the scalar singlet \( \sigma \)

\[ \mathcal{M}_E = \frac{1}{\sqrt{2}} \begin{pmatrix}
0 & h_{2e}^{\mu} v_2^{C} & 0 & h_{1e}^{\mu} v_1^{C} & 0 \\
0 & h_{2e}^{\mu} v_2^{C} & 0 & h_{1e}^{\mu} v_1^{C} & 0 \\
0 & h_{2e}^{\mu} v_2^{C} & 0 & h_{1e}^{\mu} v_1^{C} & 0 \\
0 & 0 & 0 & 0 & g_{\chi^{C}}^{\mu} v_1^{C} - \mu E \\
0 & 0 & 0 & 0 & -\mu E \\
\end{pmatrix} \]
Figure 1: Mass one-loop correction for (a) up and (b) down sector, where \( k, l, m, n = 1, 2 \) and \( j = 1, 2, 3 \).

Table 3: Lepton content of the abelian extension, non-universal \( X \) quantum number and parity \( Z_2 \).

| Left-Handed Fermions | \( X^\pm \) | Right-Handed Fermions | \( X^\pm \) |
|-----------------------|-------------|-----------------------|-------------|
| \( \tilde{\ell}_e \) = | | \( \tilde{\nu}^e \) | \( -1/3^- \) |
| \( \tilde{\nu}^e \) | \( 0^+ \) | \( \tilde{\nu}^\mu \) | \( -1/3^- \) |
| \( \tilde{\nu}^\mu \) | \( 0^+ \) | \( \tilde{\nu}^\tau \) | \( -1/3^- \) |
| \( \tilde{\nu}^\tau \) | \( -1^+ \) | \( \tilde{\nu}^e \) | \( +4/3^- \) |
| \( \tilde{\nu}^\mu \) | \( -1/3^- \) | \( \tilde{\nu}^\tau \) | \( +1/3^- \) |
| \( \tilde{\nu}^\tau \) | \( +4/3^- \) | \( \tilde{\nu}^e \) | \( +1^- \) |
| \( \tilde{E}_L \) | \( -1^+ \) | \( \tilde{E}_L^c \) | \( +2/3^+ \) |
| \( \tilde{E}_L \) | \( -2/3^+ \) | \( \tilde{E}_L^c \) | \( +1^+ \) |
| Majorana Fermions | \( \mathcal{N}_{1,2,3}^R \) | \( 0^- \) |
which in this particular case, the SUSY and non-SUSY contributions are given by:

\[
v_2 \Sigma_{11(13)}^{NS} = -\frac{1}{16\pi^2} \frac{\lambda_1 \mu_\sigma}{\sqrt{2}} \frac{h_{\text{ee}}^{\text{ee}(\tau)}}{M_E} C_0 \left( \frac{m_{h_1'}}{M_E}, \frac{m_\sigma'}{M_E} \right). \tag{16}
\]

\[
v_2 \Sigma_{11(13)}^S (p^2 = 0) = -\frac{1}{32\pi^2} \frac{\lambda_1 \mu_\sigma}{\sqrt{2}} \sum_{n=1}^{10} \sum_{k=1}^{2} Z_{L_n} \tilde{Z}_{L_n} Z_{\tilde{L}_k} Z_{\tilde{L}_k} \lambda_1 \mu_\sigma \gamma_5 h_{\text{ee}}^{\text{ee}(\tau)} h_{1E} \times
\]

\[
\times \left[ \left( \tilde{m}_{\sigma k} + \tilde{m}_{h_1'} \right)^2 \frac{M_{L_n}}{C_0 \left( \frac{\tilde{m}_{h_1'}}{M_{L_n}}, \frac{\tilde{m}_{\sigma k}}{M_{L_n}} \right) + \tilde{m}_{h_1'}^2 B_0 \left(0, \tilde{m}_{\sigma k}, \tilde{M}_{L_n}\right) + \tilde{m}_{\sigma k}^2 B_0 \left(0, \tilde{m}_{h_1'}, \tilde{M}_{L_n}\right) \right] \right]
\]

Anyway, when considering the neutral leptons, the Majorana fermions are expected to be heavy, then the standard model neutrinos acquire small mass values due to seesaw mechanism. The model generates the correct squared mass differences reported for neutrino oscillations [5]. However, that is a result that arise from the no-SUSY version of the model [1]

4 Conclusions

It is shown that the $U(1)_X$ extension of the MSSM is compatible with the SM physics and a $125GeV$ scalar particle through 4 VEV at the electroweak scale. It allows to fermions with different iso-spin to get coupled to different Higgs doublets, and showing that it is possible to get a big top-quark mass since it becomes decoupled and the corresponding VEV is found to have a big value too. Anyway, it is yet unexplored the neutralino and chargino physics as well as sfermions fenomenology. Furthermore, through parity breaking terms it can be considered the $\mu$-problem, but for it now the model implications are unexplored.
