What Can be Done for Large and Multiple Choledochal Stones?

ABSTRACT

Endoscopic retrograde cholangiopancreatography (ERCP) is commonly used in the diagnosis and treatment of bile stones. However, the presence of large and multiple stones, distal common bile duct (CBD) variations, the presence of periamplullary diverticula and a past history of surgery of the bile duct, stomach and duodenum can all decrease the chances of successful stone retrieval. Full stone extraction cannot be achieved by ERCP in 10–15% of patients with complicated choledochal stones (larger than 15 mm and/or more than 3) and such patients may require multiple ERCP procedures. Large stones (>2 cm) often require fragmentation through extracorporeal shock wave lithotripsy (ESWL) or laser lithotripsy. Despite their efficacy, these methods are not available in all centres and even increases the treatment duration. Older patients with comorbidities, in particular, cannot tolerate prolonged procedures. Alternatively, multiple biliary stenting, with sequential ERCP procedures for the treatment of large stones, facilitates the downsizing and fragmentation of the stones and serves as a bridging treatment until the next intervention, thus facilitating the retrieval of stones in follow-up endoscopic interventions.

This report presents the case of a patient with multiple large choledochal stones who was treated by multiple biliary stenting with planned and sequential ERCP.

CASE REPORT

A 68-year female patient presented to our outpatient clinic with complaints of abdominal pain and jaundice lasting approximately two weeks. Incidents of interest from her medical history were history of appendectomy, hypertension and type 2 diabetes mellitus. Upon physical examination, the patient was found to have scleral icterus, while the abdomen was normal. Vital signs were stable and arterial blood pressure was 130/85 mmHg, fasting blood glucose was 105 mg/dl, and body temperature was 37°C. Laboratory test results were as follows: white blood cells: 9,200/mm³, hemoglobin: 11.2 g/dl, neutrophils: 5,600/mm³. Biochemistry values were: aspartate aminotransferase: 35 U/L; alanine aminotransferase: 44 U/L; alkaline phosphatase (ALP): 345 U/L; gamma glutamyltransferase (GGT): 285 U/L; total bilirubin: 4.4 mg/dl; direct bilirubin: 4.1 mg/dl; C-reactive protein: 5 mg/L; and erythrocyte sedimentation rate: 12 mm/hr. An abdominal ultrasound revealed multiple stones in the gall bladder, the largest measuring 2 cm. Magnetic resonance cholangiopancreatography (MRCP) showed multiple large stones (larger than 15 mm) in the common bile duct, the diameter of which was 2 cm. The intrahepatic bile ducts and pancreatic duct were of normal width (Figure 1a).

The patient underwent endoscopic cholangiography and sphincterotomy (Figure 1b). However, the stones observed on MRCP could not be retrieved using conventional methods during the first session of ERCP. We evaluated the options of endoscopic and surgical interventions in consultation with the patient, and the possible risks of these interventions. Due to the unavailability of ESWL and laser lithotripsy in our hospital, downsizing of the stones

through the insertion of multiple stents into the common bile duct was planned. To this end, a 10 F plastic biliary stent was placed in the common bile duct every 15 days. The serum enzymes associated with cholestasis decreased after the first procedure and abdominal pain disappeared. By the end of six months, a total of 11 plastic biliary stents had been placed in the patient (Figure 2a). During the 12th procedure, a shedding of small stone fragments from the papilla was observed. At this point, the stents were removed from the common bile duct (Figure 2b) and the extrahepatic bile duct was cleaned thoroughly using the balloon/basket technique. A confirmed cholangiography revealed no remaining stones in the extrahepatic bile ducts, and the patient underwent a laparoscopic cholecystectomy four weeks later. The patient reported no problem at the follow-up visit, two months after surgery.

DISCUSSION

Choledocholithiasis is one of the most common gastrointestinal diseases requiring therapeutic endoscopic procedures. Conventional ERCP techniques (sphincterotomy, balloon or basket techniques) may fail in stone extraction in 10-15% of patients with large and multiple choledochal stones.1-4 Technical difficulties, associated with stone extraction from the distal CBD, are determined by the size and number of stones; and the rate of successful stone extraction decreases with increasing stone size.6-7 Temporary plastic stents are placed to relieve biliary obstructions when the stones cannot be extracted from the CBD, and it has been demonstrated that large stones decrease in size and even disappear after the insertion of multiple stents.5 Endoscopic large balloon dilatation or lithotripsy is performed for non-impacted stones and multiple biliary stenting is recommended for patients whose stones cannot be removed.8

While it was apparent from the MRCP and ERCP that the large stones detected during cholangiography could not be extracted in a single session, all stones were eventually eradicated after the insertion of multiple stents with sequential ERCP. Multiple biliary stenting was found to be an effective method for high-risk elderly patients with CBD stones.7

The exact mechanisms responsible for the decrease in size and number of stones following multiple stenting are unclear. It appears that multiple stenting of the extrahepatic bile duct causes friction due to respiratory movements and bowel peristalsis, which facilitates passage through the ampulla, thus providing continuity of biliary drainage. It is also possible that multiple stenting may prevent stone formation by decreasing calcium bilirubinate accumulation.6 At the same time, 10 F stents are associated with fewer obstructions and are in common use in our clinic.9 In the current case, while there was no biliary obstruction following multiple stenting, a definite decrease in the size of stones was observed.

Despite the known efficacy of ERCP and biliary stenting, there is a limited body of knowledge regarding multiple biliary stenting and its efficacy.10 It seems that a stone extraction technique involving temporary plastic biliary stent placement can be successfully performed in geriatric and high-risk patients, when stones in the CBD cannot be retrieved completely. This approach results in a decrease in both procedure time and in complication rate following ERCP.11 That said, repeated ERCP procedures, increased total procedure time and the potential for complications in individual procedures can be considered as disadvantages of this...
What can be done for large and multiple choledochal stones?

Multiple stenting with ERCP can be considered a safe, alternative method in selected patients with large, multiple choledochal stones.

PATIENTS’ CONSENT:
Informed consent was obtained from the patient.

CONFLICT OF INTEREST:
Authors declared no conflict of interest.

AUTHORS’ CONTRIBUTION:
UA: Design of the work and ERCP.
HMC: Drafting the work and ERCP.
