Abstract

**Background/Aims:** Daphnetin (7,8-dihydroxycoumarin, DAP) exhibits various bioactivities, such as anti-inflammatory and antioxidant activities. However, the role of DAP in myocardial ischaemia/reperfusion (I/R) injury and I/R-related arrhythmia is still uncertain. This study aimed to investigate the mechanisms underlying the effects of DAP on myocardial I/R injury and electrophysiological properties in vivo and in vitro. **Methods:** Myocardial infarct size was measured by triphenyltetrazolium chloride staining. Cardiac function was assessed by echocardiographic and haemodynamic analyses. The levels of creatine kinase-MB, lactate dehydrogenase, malondialdehyde, superoxide dismutase, interleukin-6 (IL-6), and tumour necrosis factor-alpha (TNF-α) were detected using commercial kits. Apoptosis was measured by terminal deoxynucleotidyl-transferase-mediated dUTP nick-end labelling staining and flow cytometry. The viability of H9c2 cells was determined by the Cell Counting Kit-8 assay. In vitro, the levels of IL-6 and TNF-α were measured by quantitative PCR. The expression levels of proteins associated with apoptosis, inflammation, and the Toll-like receptor 4/myeloid differentiation factor 88/nuclear factor kappa B (TLR4/MyD88/NF-κB) signalling pathway were detected by Western blot analysis. The RR, PR, QRS, and QTc intervals were assessed by surface ECG. The 90% action potential duration (APD\textsubscript{90}), threshold of APD alternans, and ventricular tachycardia inducibility were measured by the Langendorff perfusion technique. **Results:** DAP preconditioning decreased myocardial I/R injury and hypoxia/reoxygenation (H/R) injury in cells. DAP preconditioning improved cardiac function after myocardial I/R injury. DAP preconditioning also sup-
pressed apoptosis, attenuated oxidative stress, and inhibited inflammatory responses in vivo and in vitro. Furthermore, DAP preconditioning decreased the susceptibility to ventricular arrhythmia after myocardial I/R. Finally, DAP preconditioning inhibited the expression of TLR4, MyD88, and phosphorylated NF-κB (p-NF-κB)/P65 in mice subjected to I/R and cells subjected to H/R. **Conclusions:** DAP preconditioning protected against myocardial I/R injury and decreased susceptibility to ventricular arrhythmia by inhibiting the TLR4/MyD88/NF-κB signalling pathway. © 2021 The Author(s) Published by S. Karger AG, Basel

Introduction

Cardiovascular disease remains the leading cause of mortality and morbidity in populations around the world [1]. Myocardial ischaemia/reperfusion (I/R) injury is a clinically relevant problem that is associated with thrombolytic therapy, percutaneous transluminal coronary angioplasty, coronary artery bypass grafting, and heart transplantation, and myocardial I/R injury is a phenomenon in which reperfusion itself exacerbates myocardial injury and reduces cardiac function [2–4]. Previous studies have shown that many mechanisms are involved in myocardial I/R injury, including oxidative stress, calcium overload, inflammatory responses, and apoptosis [5, 6]. Thus, the regulation of these pathological mechanisms is important for prevention of myocardial I/R injury [7, 8].

Daphnetin (7,8-dihydroxycoumarin, DAP) is a coumarin derivative extracted from *Daphne koreana* (D. koreana) Nakai. Many studies have shown that DAP exhibits broad pharmacological effects, including anti-inflammatory, antioxidative, and antithrombotic activities [9–12]. Additionally, a recent study revealed that DAP protects against cerebral I/R injury in mice via inhibiting inflammation and apoptosis [13]. However, there have been few studies on the cardioprotective effect of DAP. Thus, the present study was designed to investigate the effect of DAP and its underlying mechanisms in an in vivo model of I/R and an in vitro model of hypoxia/reoxygenation (H/R).

Materials and Methods

**Animals**

All animal and study protocols were approved by the Ethics Committee of Renmin Hospital of Wuhan University (IACUC No. 20171224) and conducted in accordance with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (Publication No. 85–23, revised 1996). All mice used in the studies were male and 8 to 12 weeks old. All mice were maintained in an environment with constant temperature under a 12-h light/12-h dark cycle and were provided water and food ad libitum. Animal health and behaviour were monitored twice a day.

**Myocardial I/R Model**

The mice were anaesthetized using 50 mg/kg pentobarbital sodium by intraperitoneal injection. The anaesthetized mice were intubated with a PE-90 catheter and ventilated with normal PO2, PCO2, and pH using a rodent ventilator. Body temperature was maintained at 37 ± 0.5°C with a homeothermic blanket. After left thoracotomy was performed, the left anterior descending coronary artery (LAD) was exposed. Ischaemia was performed with an 8–0 silk ligature that was placed around the LAD and a piece of PE-10 tubing that was placed over the LAD. After occlusion for 45 min, reperfusion was achieved by releasing the ligature and removing the PE-10 tubing. The air was expelled from the thoracic cavity, and the chest wall was closed. Sham-operated mice underwent the same surgical procedures without LAD ligation and reperfusion.

**Experimental Groups**

To determine the optimal dose of DAP (MedChemExpress, Monmouth Junction, NJ, USA; HY-N0281), the mice were randomly assigned into 6 groups: the sham group (*n* = 13), I/R group (*n* = 14), I/R + DAP (2.5 mg/kg) group (*n* = 14), I/R + DAP (5 mg/kg) group (*n* = 14), I/R + DAP (10 mg/kg) group (*n* = 14), and I/R + DAP (20 mg/kg) group (*n* = 14) (Fig. 1a). Based on the myocardial infarct size and the levels of myocardial injury markers, the 10 mg/kg dose was determined to be the optimal dose and was used in the following experiment. For the subsequent experiment, the mice were randomly divided into 4 groups: the sham group (*n* = 35), sham + DAP (10 mg/kg) group (*n* = 35), I/R group (*n* = 37), and I/R + DAP (10 mg/kg) group (*n* = 37) (Fig. 1b). In the DAP-treated groups, DAP was diluted in 0.9% saline and administered via daily gavage for 2 days before sham operation or I/R operation. An equal volume of 0.9% saline was administered in the DAP-untreated group. For long-term follow-up, the mice in the DAP treatment groups were treated with 10 mg/kg by daily gavage. In total, 227 mice were used for the experiment.

**Infarct Size Determination**

Infarct size was assessed by triphenyltetrazolium chloride (TTC; Sigma-Aldrich, Merck KGaA) staining as described previously [14]. Briefly, the LAD was retracted, and 2% Evans blue was injected into the jugular vein to demarcate the non-perfused myocardium from the perfused myocardium after 24 h of reperfusion. The heart was removed and frozen at −20°C for 15 min. The frozen heart was sliced into 5 sections from the apex to the base and further incubated in 2% TTC at 37°C for 15 min to visualize the infarct area. Finally, the sections were fixed in 4% paraformaldehyde solution for 24 h and measured using Image-Pro Plus software (version 6.0).

**Echocardiography and Haemodynamic Measurements**

Before and 24 h, and 7 and 28 days after sham or I/R surgery, mice treated with DAP (10 mg/kg) and untreated mice underwent transthoracic echocardiographic examination. Briefly, echocar-
Daphnetin Decreases Myocardial I/R Injury and Susceptibility to Arrhythmia

Cardiac function was assessed before sham or I/R surgery. oxidative stress, and protein expression were evaluated 24 h after sham or I/R operation. Electrophysiology, inflammation, apoptosis, oxidative stress, and protein expression were evaluated 24 h after sham or I/R surgery. Cardiac function was assessed before and 24 h, and 7 and 28 days after sham or I/R operation. H9c2 cells were pretreated with different concentrations (5, 10, 20, and 40 μM) of DAP and 0.01% DMSO for 12 h and then subjected to 6 h of hypoxia and 6 h of reoxygenation or control treatment. Cell viability and apoptosis were tested in the H/R and control groups. H9c2 cells were pretreated with DAP (20 μM) and 0.01% DMSO for 12 h and then subjected to 6 h of hypoxia and 6 h of reoxygenation or control treatment. Inflammation, oxidative stress, and protein expression were tested in the H/R and control groups. I/R, ischaemia/reperfusion; H/R, hypoxia/reoxygenation; DMSO, dimethylsulphoxide.

**Fig. 1.** Experimental protocol. Different concentrations (2.5, 5, 10, and 20 mg/kg) of DAP and an equal volume of 0.9% saline were administered via daily gavage for 2 days before sham operation or I/R operation, and the myocardial infarct size and the myocardial enzyme levels were assessed 24 h after sham or I/R surgery. DAP (10 mg/kg) and an equal volume of 0.9% saline were administered via daily gavage for 2 days before sham operation or I/R operation and for the long-term follow-up (treatment starting 24 h after sham or I/R operation). Electrophysiology, inflammation, apoptosis, oxidative stress, and protein expression were evaluated 24 h after sham or I/R surgery. Cardiac function was assessed before and 24 h, and 7 and 28 days after sham or I/R operation. H9c2 cells were pretreated with different concentrations (5, 10, 20, and 40 μM) of DAP and 0.01% DMSO for 12 h and then subjected to 6 h of hypoxia and 6 h of reoxygenation or control treatment. Cell viability and apoptosis were tested in the H/R and control groups. D9c2 cells were pretreated with DAP (20 μM) and 0.01% DMSO for 12 h and then subjected to 6 h of hypoxia and 6 h of reoxygenation or control treatment. Inflammation, oxidative stress, and protein expression were tested in the H/R and control groups. I/R, ischaemia/reperfusion; H/R, hypoxia/reoxygenation; DMSO, dimethylsulphoxide.

**Immunofluorescence Analysis**

The hearts of mice treated with DAP (10 mg/kg) and untreated mice 24 h after sham or I/R surgery were harvested, fixed in 4% paraformaldehyde solution for 24 h, embedded in paraffin, and then cut into 5-μm sections. After dewaxing and antigen retrieval, the slices were incubated with an LY6G antibody (BD Biosciences, Franklin Lakes, NJ, USA) overnight at 4°C and then incubated with a rhodamine (TRITC)-conjugated goat anti-rat IgG secondary antibody (Proteintech Group, Chicago, USA) for 50 min at 37°C. Finally, the nuclei were stained with 4′,6′-diamidino-2-phenylindole (ASPEN Biotechnology Co., Ltd., Wuhan, China) at room temperature for 5 min. Each section was observed with fluorescence microscopy.

**TUNEL Assays**

Myocardial apoptosis was detected by the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labelling (TUNEL) technique. Heart tissue sections, which were prepared as for immunofluorescence, were stained using a TUNEL kit (Roche Diagnostics, Basel, Switzerland). The nuclei of apoptotic cells were stained green, and total nuclei were stained blue. The extent of cell apoptosis is presented as the percentage of apoptotic nuclei relative to total nuclei.

**Cell Culture and H/R Model Establishment**

H9c2 cells (iCell BioScience Inc., Shanghai, China) were cultured in Dulbecco’s modified Eagle’s medium (DMEM; HyClone; GE Healthcare Life Sciences, Logan, UT, USA) supplemented with 10% foetal bovine serum at 37°C in a humidified atmosphere containing 5% CO₂. In the preliminary experiments, the cells were divided into 6 groups: the control group, H/R group, H/R + DAP (5 μM) group, H/R + DAP (10 μM) group, H/R + DAP (20 μM) group, and H/R + DAP (40 μM) group (Fig. 1c). Based on the results of the Cell Counting Kit-8 (CCK-8) assay and flow cytometry, the cells were divided into 4 groups: the control group, control +

DOI: 10.1159/000513631
DAP (20 μM) group, H/R group, and H/R + DAP (20 μM) group (Fig. 1d). For hypoxia, the cells were maintained in an incubator with 1% O₂, 5% CO₂, and 94% N₂ at 37°C for 6 h. For reoxygenation, the cells were incubated in a humified atmosphere with 95% air and 5% CO₂ at 37°C for 6 h. Control cells were maintained in 95% air and 5% CO₂ at 37°C. In the DAP groups, the cells were pretreated with DAP for 12 h and then subjected to H/R or control treatment. In the DAP-untreated groups, the cells were pretreated with 0.01% dimethylsulphoxide.

**CCK-8 Assay**

Cell viability was determined using the CCK-8 assay (Beyotime Institute of Biotechnology, Shanghai, China) according to the manufacturer’s protocol. Briefly, cells were cultured in a 96-well plate and treated as previously described. Then, 10 μL of the CCK-8 solution was added to each well, and the cells were incubated for an additional 2 h at 37°C. The optical density (OD) values were measured at 450 nm using a microplate reader. The cell survival rate was calculated based on the following formula: cell survival rate (%) = (OD experiment – OD blank)/(OD control – OD blank) × 100.

**Flow Cytometry**

Cell apoptosis was detected using an annexin V-fluorescein isothiocyanate (FITC) apoptosis detection kit according to the manufacturer’s protocol (Tianjin Sungene Biotech Co., Ltd., Tianjin, China). Briefly, the cells were digested with trypsin without EDTA and centrifuged at 300 g for 5 min at 4°C. After washing twice with PBS, the cells were suspended in 300 μL of binding buffer. Then, 5 μL of Annexin V-FITC and 5 μL of propidium iodide were added to the cells and incubated for 10 min in the dark. Finally, cell apoptosis was analysed by flow cytometry (BD Biosciences, Franklin Lakes, NJ, USA).

**Biochemical Analysis**

Blood was harvested 24 h after sham or I/R surgery. The serum was isolated by centrifugation at 1,008× g for 30 min at 4°C and stored at -80°C until analysis. H9c2 cells treated with DAP (20 μM), untreated H9c2 cells from the H/R and control groups were collected and centrifuged at 2,000× g for 10 min at 4°C, and then the supernatants were harvested. The creatine kinase-MB (CK-MB), lactate dehydrogenase (LDH), malondialdehyde (MDA),...
Daphnetin Decreases Myocardial I/R Injury and Susceptibility to Arrhythmia

**Quantitative Real-Time PCR**

Total RNA was isolated from H9c2 cells treated with DAP (20 μM) and from untreated H9c2 cells from the H/R and control groups using TRIPure reagent (ELK Biotechnology Co., Ltd., Wuhan, China) according to the manufacturer’s protocols. The levels of interleukin-6 (IL-6) and tumour necrosis factor-alpha (TNF-α) were measured using commercial ELISA kits (NeoBioscience, Shenzhen, China) following the manufacturer’s instructions. The levels of in-

**Western Blot Analysis**

Total protein was extracted from the LV tissues of mice treated with DAP (10 mg/kg) and untreated mice 24 h after sham or I/R surgery and from H9c2 cells treated with DAP (20 μM) and untreated H9c2 cells from the H/R and control groups. The protein concentrations were measured by the BCA assay. An equal amount of protein was separated by SDS-PAGE and transferred to PVDF membranes (Millipore). The membranes were blocked with 5% non-fat milk for 1 h at room temperature and incubated at 4°C overnight with the following primary antibodies: intercellular adhesion molecule-1 (ICAM-1; 1:1,000, Proteintech Group, 10020–1-AP), vascular cell adhesion molecule-1 (VCAM-1; 1:2,000, Abcam, ab49822), Bcl2 (1:2,000, Abcam, ab59348), Toll-like receptor 4 (TLR4; 1:1,000, Abbiotech, AF7017), myeloid differen-

**Surface ECG Recording**

Twenty-four hours after sham or I/R surgery, the mice treated with DAP (10 mg/kg) and untreated mice were anaesthetized with pentobarbital sodium. Then, electrodes were placed subcutane-
ously, and surface lead ECG (lead II) recordings were acquired for 10–15 min. To correct for heart rate, the QTc interval was calculated with the modified Bazett’s formula (QTc = QT/(RR/100)^1/2. The data were analysed with LabChart 7 software (AD instrument).

**Fig. 4.** a, b Scatter dot plots showing quantification of the levels of TNF-α and IL-6 in the serum (n = 6). Representative Western blots (c) and scatter dot plots showing quantification of ICAM-1 and VCAM-1 expression in mouse hearts (d, e) (n = 6). Representative immunofluorescence staining and scatter dot plots showing quantification (f, g) of neutrophils (n = 7). *p < 0.05 versus the sham group; &p < 0.05 versus the I/R group; IL-6, interleukin-6; TNF-α, tumour necrosis factor-alpha; ICAM-1, intercellular adhesion molecule-1; VCAM-1, vascular cell adhesion molecule-1; I/R, ischaemia/reperfusion.

**Monophasic Action Potential Recording and Cardiac Arrhythmia Inducibility**

The mice treated with DAP (10 mg/kg) and untreated mice were anaesthetized with pentobarbital sodium 24 h after sham or I/R surgery and heparinized with heparin sodium. Then, the heart was removed and promptly perfused with Tyrode’s solution (in mmol/L: 1 MgCl₂; 5.4 KCl; 1.8 CaCl₂; 135 NaCl; 0.3 Na₂HPO₄; 10

DOI: 10.1159/000513631

Yang/Jiang/Cao/Shuai/Zhang/Wang/Quan/Jiang
glucose; and 10 HEPES; pH 7.4) by the Langendorff method. After perfusion for 20 min at 37°C, the pacing electrode was placed on the basal surface of the right ventricle. The recording electrode was positioned on the peri-infarct zone of LV. A pacing cycle length (PCL) of 150 ms was used to record the monophasic action potential (MAP). The 90% action potential duration (APD90) was measured as the average 90% repolarization time for MAP. The APD alternans was recorded under regular pacing at a reduced length from 120 ms to 100 ms in 10-ms steps and then from 100 ms to 30 ms in 5-ms steps. The maximal pacing cycle length-induced electric alternans was defined as the electric alternans threshold. Burst pacing with 2-ms pulses at 50 Hz and a 2-s burst duration was used to determine ventricular tachycardia (VT) inducibility. VT was considered to have occurred when at least 4 consecutive ventricular waveforms were observed.

**Statistical Analysis**

The data analyses were performed using SPSS 19.0. Data were presented as median. Differences between groups were assessed by non-parametric tests: Kruskal-Wallis test. Categorical data were expressed as percentages, and Fisher’s exact test was used for statistical analysis. The survival data were analysed with the Kaplan-Meier plot and were compared with the log-rank test. *p < 0.05 were considered to be statistically significant.

**Results**

**DAP Reduced Myocardial I/R Injury in Mice**

As shown in Figure 2b and c, there was no significant difference in the risk area of the LV between the untreated and DAP-treated groups 24 h after reperfusion. However, the infarct size of the risk area was significantly reduced in the DAP-treated (2.5, 5, 10, or 20 mg/kg) groups compared with the untreated group 24 h after reperfusion (Fig. 2b, d). Additionally, no further reduction in infarct size of the risk area was observed in the 20 mg/kg I/R group compared with the untreated group (Fig. 2b, d). Similarly, pretreatment with DAP (2.5, 5, 10, or 20 mg/kg) markedly reduced the levels of CK-MB and LDH 24 h after reperfusion (Fig. 2e, f), but no significant difference in the levels of CK-MB and LDH was observed between the 10 and 20 mg/kg I/R groups (Fig. 2e, f).

**DAP Increased Cardiac Function and Improved Survival Rate**

As shown in Figure 3a–c, DAP (10 mg/kg) did not exert a negative inotropic effect under sham conditions. After I/R, compared with the sham group, there were obvious reductions in EF and FS in the I/R group (Fig. 3a–c). Conversely, the DAP (10 mg/kg)-treated group showed significant increases in EF and FS compared to the untreated group after I/R (Fig. 3a–c). However, the EF and FS observed 24 h after reperfusion were similar to those observed 7 or 28 days after I/R in the DAP (10 mg/kg)-treated group (Fig. 3a–c). In addition, the minimum and maximum rates of pressure increase (dp/dt min and dp/dt max, respectively) were decreased 28 days after I/R compared with those of the sham group, whereas DAP (10 mg/kg) reversed the I/R-induced reduction in dp/dt min and dp/dt max (Fig. 3d, e). Finally, DAP (10 mg/kg) improved the 28-day survival rate after myocardial I/R (88.2 vs. 58.8%, p < 0.05; Fig. 3f).

**DAP Attenuated the Inflammatory Response, Oxidative Stress, and Cardiomyocyte Apoptosis in Mice**

As shown in Figure 4a and b, the levels of TNF-α and IL-6 were increased 24 h after reperfusion compared with those in the sham group, whereas DAP (10 mg/kg) markedly decreased the level of inflammatory cytokines (Fig. 4a, b). Western blot analysis indicated that pretreatment with DAP (10 mg/kg) markedly inhibited the I/R-induced expression of ICAM-1 and VCAM-1 (Fig. 4c–e). Immunofluorescence staining...
analysis showed that DAP (10 mg/kg) pretreatment significantly decreased the number of neutrophils after I/R (Fig. 4f, g). I/R also significantly increased the level of MDA and decreased the activity of SOD compared to the sham group (Fig. 5), but DAP (10 mg/kg) pretreatment reversed these alterations (Fig. 5).

TUNEL staining showed that the number of apoptotic myocardial cells was significantly increased in the I/R group compared to the sham group (Fig. 6a, b). Conversely, pretreatment with DAP (10 mg/kg) significantly decreased cardiomyocyte apoptosis (Fig. 6a, b). Western blot analysis showed that pretreatment with DAP (10 mg/kg) also decreased the expression of Bax and cleaved caspase-3 and increased the expression of Bcl-2 induced by I/R (Fig. 6c–f).

**DAP Decreased Susceptibility to Ventricular Arrhythmia**

As shown in Figure 7b and c, there was no difference in the RR interval or PR interval between the sham and I/R groups. The QRS and QTc intervals were prolonged after I/R compared with those of the sham group, but pretreat-
Daphnetin Decreases Myocardial I/R Injury and Susceptibility to Arrhythmia

Daphnetin Decreases Myocardial I/R Injury and Susceptibility to Arrhythmia

377 Pharmacology 2021;106:369–383
DOI: 10.1159/000513631

ment with DAP (10 mg/kg) significantly shortened the QRS and QTc intervals (Fig. 7d, e). Meanwhile, I/R markedly prolonged the APD_{90}, decreased the threshold of electric alternans, and increased the VT inducibility rate (Fig. 8). In contrast, pretreatment with DAP (10 mg/kg) inhibited the changes in the APD_{90} and threshold of electric alternans and decreased the VT inducibility rate (Fig. 8).

**DAP Inhibited the TLR4/NF-Kb Signalling Pathways in Mice**

As shown in Figure 9, I/R markedly increased the expression of TLR4, MyD88, and p-NF-κB/P65 compared with that in the sham group. However, pretreatment with DAP (10 mg/kg) significantly inhibited the expression of TLR4, MyD88, and p-NF-κB/P65 (Fig. 9).

**DAP Attenuated H/R-Induced Injury, Apoptosis, Inflammatory Cytokine Expression, and Oxidative Stress through the TLR4/NF-Kb Signalling Pathway**

As shown in Figures 10a–c, compared with the control, H/R markedly decreased cell viability and promoted cell apoptosis. Pretreatment with DAP (5, 10, 20, or 40 μM) increased cell viability and inhibited cell apoptosis (Fig. 10a–c). These changes were similar between the 20μM and 40 μM H/R groups (Fig. 10a–c). Additionally, the mRNA levels of TNF-α and IL-6 were significantly downregulated in the 20 μM H/R group compared to the H/R group (Fig. 10d, e). Furthermore, pretreatment with DAP (20 μM) dramatically reduced the levels of MDA and increased the activity of SOD after H/R (Fig. 10f, g). Finally, Western blot analysis showed that DAP (20 μM) pretreatment significantly inhibited the expression of TLR4, MyD88, and p-NF-κB/P65 in cells subjected to H/R (Fig. 11).

**Discussion**

Coumarins comprise a large class of benzopyrone substances obtained from both natural products and synthetic methods. Coumarins are known to possess a variety of pharmaceutical properties and may have promising pro-

Protective effects on I/R. For example, aesculetin or umbelliferone, which have structures similar to that of DAP, have been reported to attenuate myocardial I/R injury [16, 17]. DAP is extracted from the plants of the *D. koreana* Nakai and belongs to the coumarin family. In this study, the cardioprotective effects of DAP were examined in a myocardial I/R model and an H/R model. The results showed that DAP preconditioning reduced the infarct size and improved cardiac function. However, treatment with DAP after reperfusion did not further improve cardiac function. DAP preconditioning markedly inhibited apoptosis, inflammatory responses, and oxidative stress and decreased susceptibility to ventricular arrhythmia. Furthermore, DAP preconditioning significantly suppressed the TLR4/MyD88/NF-κB signalling pathway.

Previous studies have indicated that ROS play a double-edged role in cardioprotection [18]. A small amount of ROS may contribute to protection [19]. However, the formation of excessive ROS can lead to the denaturation of proteins, lipid peroxidation, and DNA damage. I/R can cause an imbalance in oxidants and antioxidants and result in oxidative stress [20]. The generation of excessive ROS contributes to irreversible myocardial injury [19, 21]. MDA is a marker of lipid peroxidation, and SOD is an endogenous antioxidant. Their levels may be related to the defence capacity against oxidative injuries. In the present study, preconditioning with DAP markedly increased the SOD activity and decreased the MDA levels.

The inflammatory response is a prerequisite for tissue repair in response to tissue injury [22]. Uncontrolled inflammatory responses, however, counter these beneficial effects and promote I/R-induced tissue injury [23]. Previous studies have shown that myocardial ischaemia promotes chemokine release, adhesion molecule expression, and inflammatory cell infiltration [24–26]. Additionally, these recruited inflammatory cells further mediate the release of pro-inflammatory cytokines, proteases, and ROS, which form a positive feedback loop and exacerbate tissue injury [27]. Some studies have demonstrated that inhibition of the inflammatory response is beneficial for reducing I/R injury [28–30]. Consistent with previous studies, the present study also demonstrated that I/R markedly increased the inflammatory response. However, preconditioning with DAP significantly decreased the levels of pro-inflammatory cytokines, expression of adhesion molecules, and infiltration of inflammatory cells.

Apoptosis has been demonstrated to contribute to myocardial I/R-induced injury [31]. Bcl-2 family proteins are significant regulators of apoptosis and are divided into pro-apoptotic (Bax, Bak) and anti-apoptotic (Bcl-2, Bcl-xL, etc.). In the present study, DAP preconditioning markedly increased the expression of anti-apoptotic proteins and decreased the expression of pro-apoptotic proteins.

**Fig. 11.** Representative Western blots of H9c2 cells (**a**) and scatter dot plots quantifying TLR4, MyD88, and p-NF-κB/P65 (**b–d**) (*n* = 6). *p < 0.05 versus the control group; &p < 0.05 versus the I/R group. H/R, hypoxia/reoxygenation.
Bcl-xL) proteins [32, 33]. Thus, the downregulation of Bax expression and the upregulation of Bcl-2 expression may attenuate myocardial apoptosis [34, 35]. The present study showed that DAP preconditioning markedly decreased I/R-induced cardiomyocyte apoptosis. Moreover, Western blot analysis showed that DAP preconditioning inhibited the protein expression of Bax and cleaved caspase-3 and upregulated Bcl-2 expression.

Previous studies showed that cardiac ischaemia can induce the ATP-sensitive K current, and shorten the APD and QT intervals [36]. However, the APD and QT intervals were prolonged and exceeded normal levels during the reperfusion phase [37]. Chen et al. [38] reported that I/R may inhibit the delayed rectifier potassium (IKr) channel and prolong the APD and QT interval. In I/R, excessive Ca\(^{2+}\) entry may be related to the Na\(^+/\)Ca\(^{2+}\) exchanger (NCX), and ablation of the NCX may protect against myocardial I/R injury [39]. Additionally, inhibition of the NCX may reduce the QT interval and arrhythmia [40, 41]. Previous studies showed that TLR4 activation may increase the expression of NCX, reduce the transient outward potassium current (Ito), and prolong the APD and QT interval [42, 43]. Moreover, inhibition of NF-κB may regulate the transient outward potassium current [46]. Meanwhile, recent studies suggested that the TLR4/NF-κB signalling pathway is involved in mediating myocardial I/R injury and susceptibility to arrhythmia [14, 47]. Thus, the TLR4/NF-κB signalling pathway may play an important role in I/R injury and arrhythmia. The present study showed that DAP preconditioning markedly shortened the APD and QTc intervals, increased the threshold of electric alternans, and reduced the arrhythmia inducibility rate after myocardial I/R. Western blot analysis showed that DAP preconditioning significantly inhibited the expression of TLR4, MyD88, and p-NF-κB/p65 in mice subjected to I/R and cells subjected to H/R. Thus, these results suggest that DAP preconditioning reduced myocardial I/R injury and susceptibility to ventricular arrhythmia, probably through regulation of the TLR4/MyD88/NF-κB signalling pathway.

This work also has some limitations. First, although DAP at a dose of 40 or 80 mg/kg may reduce platelet adhesion and inhibit platelet aggregation [12], it is unknown whether DAP at these doses exerts anticoagulation effects in this study. Second, this study showed that DAP preconditioning provides a cardioprotective effect. However, the effects of DAP as a postconditioning treatment at 24 h should be investigated since the therapeutic time window of cardioprotection is truly important for treating I/R injury. Third, this study indicated that DAP preconditioning changes the QT interval and APD and reduces the susceptibility to ventricular arrhythmia, and the underlying mechanisms may be related to the regulation of ion channels, such as K+ channels and the NCX. Therefore, these problems should be further researched in future studies.

In conclusion, the present study demonstrated that DAP preconditioning protects the heart against I/R injury and reduces susceptibility to ventricular arrhythmia. Furthermore, the potential mechanism of the cardioprotective effect of DAP preconditioning may be associated with the TLR4/MyD88/NF-κB signalling pathway (Fig. 12). However, treatment with DAP after reperfusion may not provide any further improvement. Thus, DAP may have potential benefits for the prevention of I/R injury related to predictable I/R stress, such as heart transplantation and cardiac surgery with aortic clamping.

**Statement of Ethics**

All animal and study protocols were approved by the Ethics Committee of Renmin Hospital of Wuhan University (IACUC No. 20171224) and conducted in accordance with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (Publication No. 85–23, revised 1996).
Conflict of Interest Statement

The authors declare that they have no conflict of interest.
