Abstract. We study plane partitions satisfying condition $a_{n+1,m+1} = 0$ (this condition is called “pit”) and asymptotic conditions along three coordinate axes. We find the formulas for generating function of such plane partitions.

Such plane partitions label the basis vectors in certain representations of quantum toroidal $\mathfrak{gl}_1$ algebra, therefore our formulas can be interpreted as the characters of these representations. The resulting formulas resemble formulas for characters of tensor representations of Lie superalgebra $\mathfrak{gl}_{m|n}$. We discuss representation theoretic interpretation of our formulas using $q$-deformed $W$-algebra $\mathfrak{gl}_{m|n}$.

1. Introduction

In this paper we study certain problems of enumerative combinatorics of 3d Young diagrams, which are motivated by representation theory.

It is convenient to identify 3d Young diagrams with plane partitions, i.e., collection of nonnegative integers $a_{i,j}$ such that $a_{i,j} \geq a_{i+1,j}$, $a_{i,j} \geq a_{i,j+1}$ and all but a finite number of $a_{i,j}$ equals 0. Later we will also consider more general plane partitions.

Denote by $|a| = \sum a_{i,j}$, i.e., the number of boxes in the corresponding 3d Young diagram. For any set $\mathcal{A}$ of plane partitions, define its generating function by $\sum_{a \in \mathcal{A}} q^{|a|}$. Such functions were extensively studied in enumerative combinatorics, for example, one of MacMahon’s formulas has the form

$$\sum_{a \in \mathcal{A}} q^{|a|} = q^{-\binom{n}{3}/3} \frac{V(1, q, \ldots, q^{n-1})}{(q^n)_\infty},$$

where $V(x_1, \ldots, x_n) = \prod_{i<j} (x_i - x_j)$ is the Vandermonde product and by $(q)_\infty = \prod_{k=1}^{\infty} (1 - q^k)$. The limit $n \to \infty$ gives well-known MacMahon formula for the generating function of all plane partitions: $\sum_a q^{|a|} = \prod_{k=1}^{\infty} (1 - q^k)^{-k}$.

We study plane partitions satisfying the condition

$$a_{n+1,m+1} = 0. \quad (1.1)$$

We will call such condition “pit” in box $(n+1, m+1)$. Moreover we will consider plane partitions $a = \{a_{i,j}\}$ with an infinite number of non-zero $a_{i,j}$ and some of $a_{i,j}$ equal to $\infty$, satisfying the following asymptotic conditions

$$1. \lim_{j \to \infty} a_{i,j} = \nu_i, \quad 2. \lim_{i \to \infty} a_{i,j} = \mu_i, \quad 3. a_{i,j} = \infty \text{ iff } (i,j) \in \lambda, \quad (1.2)$$

where $\nu, \mu, \lambda$ are partitions (see Fig. $\text{[\Pi]}$).
We denote by $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ the generating function of plane partitions which satisfy (1.1), (1.2) (for the definition of $|a|$ see (2.1)). It follows from these conditions that $l(\nu) \leq n$, $l(\mu) \leq m$, and $\lambda_{n+1} < m + 1$.

Note that asymptotic conditions (1.2) appear in the theory of topological vertex [36]. The condition (1.1) also appeared in the strings theory, see [24]. Our motivation comes from representation theory, which we discuss below.

In some particular cases the formulas for functions $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ were known before. In order to write down the answers we need some notation. By $\rho_n$ we denote the partition $(n-1, n-2, \ldots, 1, 0)$, we omit the index $n$ and write just $\rho$ if the number of parts is clear from the context. For any partition of no greater then $n$ parts $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n)$ by $q^{\lambda+\rho}$ we denote $(q^{\lambda_1+n-1}, \ldots, q^{\lambda_n})$. By $a_{\lambda+\rho}(x_1, \ldots, x_n)$ we denote the antisymmetric polynomial:

$$a_{\lambda+\rho}(x_1, \ldots, x_n) = \det \left( x_i^{\lambda_j+n-j} \right)_{i,j=1}^n.$$  \hfill (1.3)

The formula for $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ is known in the case $m = 0$, i.e., when the “pit” is located near the “wall”. Namely

$$\chi_{\emptyset,\nu,\lambda}^{n,0}(q) = \frac{q^{\sum_{i=1}^n (\lambda_i+n-i)(\nu_i+n-i)}}{(q)_\infty^{n}} a_{\nu+\rho}(q^{-\lambda-\rho}),$$  \hfill (1.4)

see, for example, [10, Theorem 4.6]. Clearly this is a generalization of the MacMahon formula given above. Another known case is where two asymptotic conditions vanish $\lambda = \mu = \emptyset$, see [19], [20].

In our paper we find the formula for $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ in general case. Actually we prove three formulas, which are algebraically equivalent but have different form and meaning. They are given in Theorems 1, 2, 3 below. Here we give the simplest (but already new) particular
case of Theorem 2

\[ \chi_{\mu,\nu,\lambda}(q) = \sum_{A_1 > A_2 > \ldots > A_n \geq 0} (-1)^{\sum_{i=1}^{n} A_i} \sum_{q=1}^{n} (A_{i+1}) a_{\nu+\rho}(q^A) a_{\mu+\rho}(q^{-A}) \left(\frac{q^n}{\sum_{i=1}^{n} (A_i^2) + 2} \right)^{a_{\nu+\rho}(A)} \left(\frac{q^n}{\sum_{i=1}^{n} (A_i^2) + 2} \right)^{a_{\mu+\rho}(A)} \left(\frac{q^n}{\sum_{i=1}^{n} (A_i^2) + 2} \right)^{a_{\lambda}(A)} \right), \quad (1.5) \]

Note that each summand is a product of two expressions on the right side of (1.4) (up to the factor of the form \((-1)^* q^*)

Since our three formulas are algebraically equivalent it is enough to prove any of them. We give two different combinatorial proofs, one for Theorem 1 and one for Theorem 3. These proofs are simpler than ones of particular cases given in [19], [20].

The first proof is based on a bijection between plane partitions and collections of non-crossing paths. The number of such collections is computed using Lindström–Gessel–Viennot lemma [30], [23]. Such proof gives a determinantal expression for \(\chi_{n,m}^{\mu,\nu,\lambda}(q)\), see Theorem 1.

In the second proof we interpret conditions (1.1), (1.2) as a definition of certain infinite dimensional polyhedron. We compute the generating function of integer points in this polyhedron as a sum of contribution of vertices, using Brion theorem [6]. Such proof gives a “bosonic formula” for \(\chi_{n,m}^{\mu,\nu,\lambda}(q)\), see Theorem 3.

We conjecture that there exist resolutions of \(\mathcal{N}_{n,m}^{\mu,\nu,\lambda}(v)\) such that their Euler characteristics coincide with our character formulas. In such cases we say that the resolution is a materialization of the character formula. For example, the BGG resolution [5] is a materialization of the Weyl character formula. Zelevinsky constructed complex which is a materialization of the Jacobi–Trudi formula for Schur polynomials [41].

Our formulas for functions \(\chi_{n,m}^{\mu,\nu,\lambda}(q)\) resemble the formulas for characters of tensor representations of Lie superalgebra \(\mathfrak{g}l_{m|n}\). This similarity can be explained by the fact that the representations \(\mathcal{N}_{n,m}^{\mu,\nu,\lambda}(v)\) are actually representations of certain q-deformed W-algebra, which we call \(W_{\mathfrak{g}l_{n|m}}\).

Such W-algebras appear as follows. There is an easy (but not written in the literature) fact that \(\mathcal{N}_{n,m}^{\mu,\nu,\lambda}(v)\) is a subfactor of Fock representation of \(U_{\mathfrak{g}l_{1}}\). This Fock module is a tensor product of \(n + m\) basic Fock modules, see the formula (5.17). And such Fock modules the algebra \(U_{\mathfrak{g}l_{n}}\) acts through the its quotient which is called W-algebra. This W-algebra commutes with certain intertwining operators, which are called screening operators. The structure of screening operators in our case suggests the name \(W_{\mathfrak{g}l_{n|m}}\).

There exists the conformal limit \(\bar{q} \to (1, 1, 1)\) of screening operators and we denote the limit of the algebra \(W\) by \(W(\mathfrak{g}l_{n|m})\). For \(m = 0\) this algebra coincides with the algebra \(W(\mathfrak{g}l_{n})\) [9]. The algebras \(W(\mathfrak{g}l_{n|1})\) conjecturally coincide with the “zero momentum”

1Usually a formula is called bosonic if it equals a linear combination of characters of algebra of polynomials. In our case bosonic formula is a combination of terms \(q^\Delta/(q)^{n+m}\).
sector of $W^{(2)}_n$ algebras introduced in [21]. We did not find reference for generic $n, m$ (note that our $W$-algebras differ from ones introduced in [27]).

Standard statement in the theory of vertex algebras is an equivalence of the abelian categories of certain representations of vertex algebra and certain representations of quantum group. This is a statement similar to Drinfeld–Kohno or Kazhdan–Lusztig theorems. We conjecture that under this equivalence $\mathcal{W}(\dot{\mathfrak{gl}}^{n|m}|m)$ is related to the product of quantum groups $U_q\mathfrak{gl}^{n|m} \otimes U_{q'}\mathfrak{gl}^{n} \otimes U_{q''}\mathfrak{gl}^{m}$. And representations $\mathcal{N}_{\mu,\nu,\lambda}^{m,n}(v)$ under this equivalence goes to the tensor products $L^{(n|m)}_{\lambda} \otimes L^{(n)}_{\nu} \otimes L^{(m)}_{\mu}$, where $L^{(n|m)}_{\lambda}$ and $L^{(n)}_{\nu}$, and $L^{(m)}_{\mu}$ are also depend on $\nu$ but we omit this dependence for simplicity.

In the end of the introduction we mention two recent (appeared in arXiv after the first version of this article) papers where the same $W$ algebras were studied in the framework of conformal field theory [31] and supersymmetric gauge theory [22].

Plan of the paper. In Section 2 we give precise statements of our main results for $\chi^{n,m}_{\mu,\nu,\lambda}(q)$ with necessary notation and comments. The remaining sections 3, 4, 5 are independent of each other. Sections 3 and 4 are devoted to the combinatorial proofs based on Lindström–Gessel–Viennot lemma and Brion theorem, correspondingly. Section 5 is devoted to the algebraic discussion. First we give a definition of appropriate $W$-algebras in terms of screening operators. Conjectural materializations of our character formulas are discussed in subsection 5.5. Relation to quantum group $U_q\mathfrak{gl}^{n|m} \otimes U_{q'}\mathfrak{gl}^{n} \otimes U_{q''}\mathfrak{gl}^{m}$ is discussed in subsection 5.7.

Acknowledgments. We thank A. Babichenko, E. Gorsky, A. Kirillov, A. Litvinov, I. Makhlin, G. Mutafyan, G. Olshansky, Y. Pugai, A. Sergeev for interest to our work and discussions. We are grateful to anonymous referee for the careful reading and huge number of valuable comments.

The article was prepared within the framework of a subsidy granted to the National Research University Higher School of Economics by the Government of the Russian Federation for the implementation of the Global Competitiveness Program. 2. Main Results

2.1. Due to asymptotic conditions (1.2) $a_{i,j} \geq \nu_i$ and $a_{i,j} \geq \mu_j$. In order to define the grading $|a| = \sum a_{i,j}$, we need to subtract these asymptotic values $\nu_i$, $\mu_j$.

We will use the following definition

$$|a| = \sum_{i-n \leq j \geq m, (i,j) \notin \lambda} (a_{i,j} - \nu_i) + \sum_{i-n > j \geq m, (i,j) \notin \lambda} (a_{i,j} - \mu_j).$$

Note that this definition of grading is not invariant under $m, \mu \leftrightarrow n, \nu$ symmetry. Geometrically the definition (2.1) can be restated as follows. We draw a staircase line from the point $(n, m)$ as on the picture below. This line divides the base of the plane partition
a into two parts. We subtract $\nu_i$ from cells in the upper part and $\mu_j$ from cells in the left part, see Fig. 2.

Let $r = \min\{t \mid \lambda_{n-t} \geq m-t\}$, $0 \leq r \leq \min\{n, m\}$. Geometrically $r$ is the number of horizontal steps in the staircase line starting from the point $(m, n)$. In the Fig. 2 we have $r = 2$. Note that this number $r$ has an interpretation in terms of representation theory of $\mathfrak{gl}(m|n)$, namely, $r$ is called the degree of atypicality (or simply atypicality) of the tensor representation of $\mathfrak{gl}(m|n)$ corresponding to $\lambda$ (see, for example [35, page 9]).

In order to write down the formula for the generating function we parametrize $\lambda$ by some analogue of Frobenius coordinates. We introduce two partitions $\pi, \kappa$ by $\pi_i = \lambda_i - (m-r)$ for $i = 1, \ldots, n-r$ and $\kappa_j = \lambda'_j - (n-r)$ for $j = 1, \ldots, m-r$, where $\lambda'$ denotes transpose of the partition $\lambda$. We denote components of partitions $\nu, \mu, \pi, \kappa$ shifted by $\rho$ by the corresponding capital Latin letters: $N_i = \nu_i + n - i$, $M_j = \mu_j + m - j$, $P_i = \pi_i + (n-r) - i$, $Q_j = \kappa_j + (m-r) - j$.

**2.2.** In the simplest case $n = 1, m = 0$ for any asymptotic conditions $\lambda, \nu$ the generating function of partitions $\chi^{1,0}_{\emptyset, \nu, \lambda}(q)$ equals $1/(q)_\infty$ (and similarly for $n = 0, m = 1$ case).

Now consider the $n = m = 1$ case. If $\lambda \neq \emptyset$ then the plane partitions decompose into two partitions so the generating function equals $1/(q)_\infty^2$. In the case $\lambda = \emptyset$, there is a clear bijection between plane partitions and $V$-partitions [39] i.e. the $\mathbb{N}$-arrays of integer numbers:

$$\left(\begin{array}{cccc} a_0 & a_1 & a_2 & a_3 & \ldots \\ b_0 & b_1 & b_2 & b_3 & \ldots \end{array}\right),$$

such that $a_0 \geq a_1 \geq a_2 \geq \ldots$, $a_0 \geq b_1 \geq b_2 \geq \ldots$, $\lim_{i \to \infty} a_i = \nu_1$, $\lim_{i \to \infty} b_i = \mu_1$. The weight of $V$-partition is defined as

$$N = \sum_{i \geq 0} (a_i - \nu_1) + \sum_{i \geq 1} (b_i - \mu_1).$$
Lemma 2.1. The generating function of $V$-partitions with asymptotic conditions $\lim_{i \to \infty} a_i = \nu_1$, $\lim_{i \to \infty} b_i = \mu_1$ equals
\[
R(d; q) := \sum_{i=0}^{\infty} (-1)^i \frac{q^{i(i+1)/2} q^{di}}{(q)_2^\infty},
\]
where $d = \nu_1 - \mu_1$.

This lemma was proven in the case $\nu_1 = \mu_1$ in [39, Sec. 2.5] by a kind of inclusion-exclusion argument. Actually this proof works for any values of $\mu_1, \nu_1$. See also [13, Cor. 5.6] for another proof.

Now we can write down the first formula for $\chi_{\mu,\nu,\lambda}^{n,m}(q)$.

Theorem 1. The generating function $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ is equal to the determinant of a block matrix of the size $(m+n-r) \times (m+n-r)$
\[
\chi_{\mu,\nu,\lambda}^{n,m}(q) = \frac{(-1)^{m-n} q^{-\Delta_{\mu,\nu,\lambda}^{m,n}}}{(q)_m^{m+n}} \det \left( \sum_{a \geq 0} (-1)^a q^{(a+1)/2} q^{(N_j-M_i)a} \right)_{1 \leq i \leq m, 1 \leq j \leq n},
\]
where $\Delta_{\mu,\nu,\lambda}^{m,n} = \sum_{j=1}^{m-r} M_j Q_j + \sum_{i=1}^{n-r} N_i (P_i + 1)$.

Clearly this formula generalizes previous considerations in the cases $(n, m) = (1, 0), (1, 1)$ or $(m, n) = (0, 1)$, where determinant becomes $1 \times 1$.

Remark 2.1. One can think that the formula (2.3) is similar to Jacobi–Trudi formula, which expresses generic Schur polynomial $s_\lambda$ in terms of Schur polynomials corresponding to rows (or columns). Since determinant formula (2.3) also has terms corresponding to thin hooks it is better to think that this formula is similar to Lascoux–Pragacz formula [28] for Schur polynomials, which is common generalization of Jacobi–Trudi and Giambelli formulas. We do not know any interpretation of this analogy.

Theorem 1 is proven in Section 3. It is natural that the determinant expression for the generating function can be proven using non-intersecting paths and Lindström–Gessel–Viennot lemma.

Let us mention two more special cases where we have only one block in the matrix. In the case of $m = 0$, we have $r = 0$, $\pi = \lambda$ and after a multiplication on $(q)_\infty^n\nu$ the determinant becomes equal to $a_{\nu + \rho}(q^{-\lambda - \rho})$. So we get the known formula (1.4).

In the case $m = n$ and $\lambda = \emptyset$, the formula (2.3) simplifies to $\det \left( R(N_j - M_i; q) \right)$. This formula was proven in [20] (following [13]) under the additional assumption that $\mu = \emptyset$.

2.3. The determinant in formula (2.3) can be calculated.

Theorem 2. The generating function $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ is equal to the sum over $r$-tuples of integer numbers $A_1 > A_2 > \ldots > A_r \geq 0$
\[
\chi_{\mu,\nu,\lambda}^{n,m}(q) = \sum_{A_1 > A_2 > \ldots > A_r \geq 0} (-1)^{r(m+n)} q^{-\Delta_{\mu,\nu,\lambda}^{m,n}} \frac{a_N(A^q - 1) a_M(q^{-A^q} - 1)}{(q)_m^{m+n}},
\]
where $a_N, a_M$ were defined in formula (1.3) and $\Delta_{\mu,\nu,\lambda}^{m,n} = \sum_{j=1}^{m-r} M_j Q_j + \sum_{i=1}^{n-r} N_i (P_i + 1)$.
Lemma 2.2. The r.h.s. of (2.3) and (2.4) are equal.

Our proof of this lemma is based on a direct calculation, which we present in Subsection 3.4.

There are two special cases in which the right hand side takes a simpler form. These two special cases of the theorem were known.

First, if \( m = 0 \) then the formula (2.4) reduce to (1.4). More generally if \( r = 0 \), then base of the plane partition decomposes into two connected components and the formula (2.4) becomes a product \( q^{m,n}_{µ,ν,λ}a_N(q^{-P-1})a_M(q^{-Q})/(q)_∞^{m+n} \).

In the second case we take \( λ = µ = ν = ∅ \). Then the functions \( a_N \) and \( a_M \) reduce to Vandermonde products and we can write (we assume that \( n ≥ m \))

\[
\chi_{n,m,∅}^{m,n} ∑_{1≤i<j≤m} (−1)^{i−j} q^{a_i−a_j} \prod_{1≤i<j≤m} (1−q^{a_i−a_j}) \prod_{1≤i<j≤n} (1−q^{a_i−a_j}).
\]

Here we set \( α_j = 0 \) for \( j > m \). This formula coincides with the [13, Conjecture 5.10] proved in [19, Theorem 1.2] by a completely different method.

2.4. The sum in formula (2.4) contains zero terms if one of \( A_i \) equals to one of \( Q_j \). We want to exclude such terms. The following lemma is standard.

Lemma 2.3. For any partition \( λ \) we have

\[
Z = \{λ'_j - j - (n - m)| j ∈ \mathbb{N}\} \bigcup \{i - λ_i - (n - m) - 1|i ∈ \mathbb{N}\}.
\]

Sketch of the proof. The proof is based on the following construction. Rotate Young diagram corresponding to \( λ \) by 135° and take a projection on \( OX \). On the Fig 3 we give an example for \( λ = (4, 4, 4, 3, 3, 1) \).
It is easy to see that \( x \)-coordinates of white balls are \( i - \lambda_i - \frac{1}{2} \) and coordinates of black ones are \( \lambda_j' - j + \frac{1}{2} \). Therefore \( \mathbb{Z} + \frac{1}{2} = \{ \lambda_j' - j + \frac{1}{2} \} \cup \{ i - \lambda_i - \frac{1}{2} \} \). Shifting by \(-(n-m) - \frac{1}{2}\) we get the Lemma. \( \square \)

Recall that
\[
Q_j = \kappa_j - j + m - r = \lambda_j' - j - (n-m) \quad \text{for } 1 \leq j \leq m - r.
\]
Note that \( \lambda_j' - j - (n-m) \geq 0 \) if and only if \( 1 \leq j \leq m - r \). Since \( A_1, \ldots, A_r \geq 0 \) and \( A_i \neq Q_j \) then it follows from the Lemma 2.3 that \( \{ A_i \} \) should be a subset in the set \( \{ i - \lambda_i - (n-m) - 1 | i \in \mathbb{N} \} \). Note that \( i - \lambda_i - (n-m) - 1 \geq 0 \) if and only if \( i > n - r \). Therefore, the non-zero terms correspond to subsets \( \{ A_r, \ldots, A_1 \} \subset \{-L_i | i > n-r\} \), where \( L_i = \lambda_i - i + n - m + 1 \). Rewriting the determinants in (2.4) as sums over permutations we get the following result.

**Theorem 3.** The generating function \( \chi_{\mu,\nu,\lambda}^{n,m}(q) \) is equal to the sum
\[
\chi_{\mu,\nu,\lambda}^{n,m}(q) = (-1)^{r(m+n)} \sum_{(\sigma,\tau,A) \in \Theta} (-1)^{|\sigma|+|\tau|+\sum_{i=1}^{r} A_i} \frac{q^{\Delta^{\sigma,\tau,A}(\mu,\nu,\lambda)}}{(q)_{\infty}^{n+m}},
\]
where
\[
(\sigma, \tau, A) \in \Theta \Leftrightarrow \sigma \in S_n, \tau \in S_m, A_{r-i+1} = -L_{s_i}, \text{ for } s_r > \cdots > s_1 > n - r,
\]
and
\[
\Delta^{\sigma,\tau,A}(\mu,\nu,\lambda) = \sum_{i=1}^{r} A_i \left( \frac{A_{i+1}}{2} + N_{\sigma(i)} - M_{\tau(i)} \right) - \sum_{i=r+1}^{n} (P_{s-i+1})(N_{\sigma(i)} - N_{s-i}) - \sum_{i=r+1}^{m} Q_{s-i}(M_{\tau(i)} - M_{s-i}).
\]

This theorem will be proven in Section 4. In this proof we consider inequalities \( a_{i,j} \geq a_{i+1,j}, a_{i,j} \geq a_{i,j+1} \) and conditions (1.2) as a definition of a polyhedron (infinite dimensional) and the generating function \( \chi_{\mu,\nu,\lambda}^{n,m}(q) \) as a sum over integer points in the polyhedron. This sum is calculated using Brion theorem \( \text{[6]} \). Each term in (2.6) corresponds to a vertex contribution in Brion theorem.

### 3. Lattice paths

**3.1.** Let \( G \) be an oriented graph with set of vertices \( V \) and set of edges \( E \). For any edge \( e \in E \) we assign a weight \( w(e) \). For any path \( p = (e_1, e_2, \ldots, e_n) \) we define the weight as a product of the edge weights \( w(p) = \prod w(e_i) \).

For any two vertices \( s, t \) we denote \( P(s \rightarrow t) = \sum_p w(p) \), where the summation goes over all paths from \( s \) to \( t \). Below we will assume that \( P(s \rightarrow t) \) is well-defined. Usually this follows from the condition that number of paths from \( s \) to \( t \) is finite (for example in \( \text{[1]} \) this follows from the conditions that \( G \) is finite and has no oriented cycles). In our case the weight of the edge \( w(e) \in \{ q^{\mathbb{Z}_{\geq 0}} \} \), where \( q \) is a formal variable, and we assume that for any fixed \( H \in \mathbb{Z}_{\geq 0} \) number of paths from \( s \) to \( t \) of the weight \( q^H \) is finite. Then \( P(s \rightarrow t) \) is well-defined as a formal series on \( q \), \( P(s \rightarrow t) \in \mathbb{C}[q] \).
For any sets of \( n \) source vertices \( S = \{s_1, \ldots, s_n\} \) and \( n \) target vertices \( T = \{t_1, \ldots, t_n\} \) we denote \( P(S \rightarrow T) = \sum_{p_1,\ldots,p_n} w(p_1) \cdots w(p_n) \), where the summation goes over all sets of paths such that \( p_i \) goes from \( s_i \) to \( t_i \). Clearly \( P(S \rightarrow T) = P(s_1 \rightarrow t_1) \cdots P(s_n \rightarrow t_n) \).

By \( P_{nc}(S \rightarrow T) \) we denote the sum \( \sum_{p_1,\ldots,p_n} w(p_1) \cdots w(p_n) \) where set of paths is assumed to be without crossings. The Lindström-Gessel-Viennot lemma provides an efficient way to find \( P_{nc}(S \rightarrow T) \). Standard references for this lemma are [30], [23], for the clear introduction see [1].

**Lemma** (Lindström-Gessel-Viennot). For an oriented graph \( G \) as above and any sets of sources and targets \( S = \{s_1, \ldots, s_n\}, T = \{t_1, \ldots, t_n\} \) we have

\[
\sum_{\sigma \in S_n} (-1)^{|\sigma|} P_{nc}(S \rightarrow \sigma(T)) = \det \left( P(s_i \rightarrow t_j) \right)_{i,j=1}^n
\]

In most examples (and in all examples in this paper) \( P_{nc}(S \rightarrow \sigma(T)) \neq 0 \) for only one permutation \( \sigma \). In this case

\[
P_{nc}(S \rightarrow \sigma(T)) = (-1)^{|\sigma|} \det \left( P(s_i \rightarrow t_j) \right)_{i,j=1}^n.
\]

**3.2.** In this paper we use graph \( G \) with vertices \((a+\frac{1}{2}, b)\), where \( a, b \in \mathbb{Z}, b \geq 0 \). There are two types of edges namely the horizontal ones \((a+\frac{1}{2}, b) \rightarrow (a+\frac{3}{2}, b)\) (\( \rightarrow \) denotes orientation) and vertical ones \((a+\frac{1}{2}, b) \rightarrow (a+\frac{1}{2}, b+1)\) for \( a < 0 \) and \((a+\frac{1}{2}, b) \leftarrow (a+\frac{1}{2}, b+1)\) for \( a \geq 0 \). The weight of a vertical edge is 1, the weight of a horizontal edge on the line \( y = b \) is \( q^b \).

Note that the number of paths from \( s = (\frac{1}{2}, b) \) to \( t = (\frac{1}{2} + a, 0) \), \( a, b \geq 0 \) is equal to the binomial coefficient \( \binom{a+b}{b} \). The number of paths counted with weights is equal to the \( q \)-binomial coefficient \( P(s \rightarrow t) = \left[ \begin{array}{c} a+b \\ b \end{array} \right]_q \).

We will use “infinitely remote” source and target vertices, see an example in Fig. 4. We say that a path starts at the point \((-\infty, b)\) if the path contains all sufficiently left edges on the horizontal line \( y = b \). Similarly we define paths which start at the point \((a, +\infty)\) or go to the point \((+, b)\) or \((a, +\infty)\). For example, the paths from the point \( s = (-\infty, 0) \) to \( t = (-\frac{1}{2}, +\infty) \) are in one to one correspondence with Young diagrams. And in this case \( P(s \rightarrow t) \) is equal to the generating function of Young diagrams \( 1/(q)_\infty \).

For the “infinitely remote” source and target vertices we need to define the weight of the path. The problem happens for the vertices \((-\infty, b)\) since their paths contain infinitely many horizontal edges on the line \( y = b \) and therefore the weights of these paths are not defined. We divide by \( q^b \) the weight of each horizontal edge (of such paths) over the point \((i, 0), i < 0 \). Clearly there is no more than one such edge, if there is none we just divide the weight of the path by \( q^b \). Informally speaking, we assign the weight \( q^{-b(i/2-1/2)} \) to the vertex \((-\infty, b)\). For example, for \( s = (-\infty, b), t = (-a - \frac{1}{2}, +\infty) \), \( a, b \geq 0 \) we have \( P(s \rightarrow t) = q^{-ab}/(q)_\infty \).

For the \((+, b)\) we divide by \( q^b \) the weight of each horizontal edge (of path to the \((+\infty, b)\)) over the point \((i, 0), i \geq 0 \). Informally speaking we assign the weight \( q^{-b(i/2+1/2)} \) to the vertex \((+\infty, b)\). For example, for \( s = (a + \frac{1}{2}, +\infty), t = (+\infty, b) \), \( a, b \geq 0 \) we have \( P(s \rightarrow t) = q^{-(a+1)b}/(q)_\infty \).
Now we prove the formula (1.4) for the number of plane partitions with \( n \) rows and asymptotic conditions.

**Proposition 3.1.** The generating function of plane partitions \( \{a_{i,j}\} \), such that \( 1 \leq i \leq n, j \in \mathbb{N}, (i, j), a_{i,j} = \infty \) iff \((i, j) \in \lambda, \lim_{j \to \infty} a_{i,j} = \nu_i \) has the form

\[
\chi_{n,0,\nu,\lambda}(q) = \frac{q^{\sum_{i=1}^{n}(\lambda_i+n-i)(\nu_i+n-i)}}{(q)_{\infty}} a_{\nu+\rho}(q^{-\lambda-\rho}).
\]

**Proof.** There is a natural bijection between such plane partitions and collections of non-intersecting paths from \( S = \{s_1, \ldots, s_n\}, s_i = (\lambda_i + n - i + \frac{1}{2}, +\infty) \) to \( T = \{t_1, \ldots, t_n\}, t_i = (+\infty, \nu_i + n - i) \). The first row of the plane partition encodes the path from \( s_1 \) to \( t_1 \), the second row of the plane partition encodes the path from \( s_2 \) to \( t_2 \) and so on. The coordinates of the sources and targets are specified in such a way that plane partition condition \( a_{i,j} \geq a_{i+1,j} \) is equivalent to the non-intersection of paths.

In the Fig. 4 we give an example, where \( n = 3, \lambda = (2, 1, 1), \nu = (3, 1, 1) \).

![Figure 4](image)

As was noted before we have \( P(s_i \to t_j) = q^{-(\lambda_i+n-i+1)(\nu_j+n-j)}/(q)_{\infty} \). Therefore using Lindström-Gessel-Viennot lemma we get

\[
P(S \to T) = \det \left( \frac{q^{-(\lambda_i+n-i+1)(\nu_j+n-j)}}{(q)_{\infty}} \right).
\]

Note that the function \( P(S \to T) \) differs from \( \chi_{n,0,\nu,\lambda}^{n,0}(q) \) by a certain power of \( q \) since our grading on paths differs slightly from the definition (2.1). In particular, \( \chi_{n,0,\nu,\lambda}^{n,0}(q) \) has the leading term 1, but \( P(S \to T) \) has the leading term \( q^{-\sum_i(\lambda_i+n-i+1)(\nu_i+n-i)} \). Multiplying \( P(S \to T) \) by \( q^{\sum_i(\lambda_i+n-i+1)(\nu_i+n-i)} \) we get Proposition 3.1.

**3.3.** We have not discussed one type of paths between “infinitely remote” vertices. Namely let \( s = (-\infty, b), t = (+\infty, a) \). Then the paths from \( s \) to \( t \) are in one-to-one correspondence with \( V \)-partitions with asymptotic conditions \( \lim_{i \to \infty} a_i = a, \lim_{i \to \infty} b_i = b \), see Fig. 5.

Recall that the generating function of \( V \)-partitions was given in Lemma 2.1 and equals \( R(a-b;q) \). Now we are ready to prove Theorem [1].
Proof of Theorem 1. First, we use a one-to-one correspondence between plane partitions satisfying (1.2), (1.1) and certain lattice paths. We decompose the base of plane partition into $r$ infinite hooks, $m - r$ infinite columns and $n - r$ infinite rows.

We set the sources and targets to be the points

$$s_i = \begin{cases} (-\infty, M_i) & \text{for } 1 \leq i \leq m, \\ (P_{i-m} + \frac{1}{2}, +\infty) & \text{for } m + 1 \leq i \leq m + n - r, \end{cases}$$

$$t_j = \begin{cases} (+\infty, N_j) & \text{for } 1 \leq j \leq n, \\ (-Q_{j-n} - \frac{1}{2}, +\infty) & \text{for } n + 1 \leq j \leq m + n - r. \end{cases}$$

We illustrate the correspondence in the Fig. 6, where we have $n = 3$, $m = 2$, $\lambda = (2, 1, 1)$, $\nu = (3, 1, 1)$, $\mu = (2, 0)$. By previous definitions $r = 1$, $\pi = (1, 0)$, $\kappa = (1)$, $N_1 = 5$, $N_2 = 2$, $N_3 = 1$, $M_1 = 3$, $M_2 = 0$, $P_1 = 2$, $P_2 = 0$, $Q_1 = 1$.

Due to our order of $s_i$ and $t_j$ non-intersecting paths correspond to the permutation

$$\begin{pmatrix} s_1 & s_2 & \ldots & s_{m-r} & s_{m-r+1} & \ldots & s_m & s_{m+1} & \ldots & s_{m+n-r-1} & s_{m+n-r} \\ t_{n+1} & t_{n+2} & \ldots & t_{m-n-r} & t_{n-r+1} & \ldots & t_n & t_1 & \ldots & t_{n-r-1} & t_{n-r} \end{pmatrix}$$
We denote this permutation of indexes 1, \ldots, m + n - r by \sigma_{m,n,r}. So we proved that
\[ \chi'^m_{\mu,\nu,\lambda}(q) = q^{-1}P(S \rightarrow \sigma_{m,n,r}(T)). \]

We compute the value \( P(S \rightarrow \sigma_{m,n,r}(T)) \) from the Lindström-Gessel-Viennot lemma. The number of inversions in the permutation \( \sigma_{m,n,r} \) is equal to \( mn - r^2 \). It remains to evaluate \( P(s_i \rightarrow t_j) \), which have been actually found above
\[
P(s_i \rightarrow t_j) = \begin{cases} R(N_j - M_i; q) & \text{for } 1 \leq i \leq m, \quad 1 \leq j \leq n, \\ q^{-M_i Q_j - n} / (q) & \text{for } 1 \leq i \leq m, \quad n + 1 \leq j \leq m + n - r, \\ q^{-N_j(P_i - m + 1)} / (q) & \text{for } m + 1 \leq i \leq m + n - r, \quad 1 \leq j \leq n, \\ 0 & \text{for } m + 1 \leq i \leq m + n - r, \quad n + 1 \leq j \leq m + n - r. \end{cases}
\]

Combining all together we obtain Theorem 1. As above, the additional factor \( q^{\sum_{j=1}^{m-r} M_j Q_j + \sum_{i=1}^{n} N_i Q_i} \) comes from the difference between definition of grading in terms of paths and \( (2.1) \).

3.4. In this Subsection we prove Lemma 2.2.

Proof. We want to calculate the determinant of the matrix
\[
M = \begin{pmatrix} \left( \sum_{a \geq 0} (-1)^a q^{a+1} q^{N_j - M_i} a_{1 \leq i \leq m, 1 \leq j \leq n} \right) & \left( q^{-M_i Q_j} a_{1 \leq i \leq m, 1 \leq j \leq m - r} \right) \\ q^{-N_j(P_i - 1)} a_{1 \leq i \leq n - r, 1 \leq j \leq n} & 0 \end{pmatrix}.
\]

Denote
\[
\tilde{M} = \begin{pmatrix} \left( \sum_{a \geq 0} (-1)^a q^{a+1} q^{N_j - M_i} a_{1 \leq i \leq m, 1 \leq j \leq n} \right) & \left( (-1)^Q_j q^{Q_j+1} q^{-M_i Q_j} a_{1 \leq i \leq m, 1 \leq j \leq m - r} \right) \\ q^{-N_j(P_i - 1)} a_{1 \leq i \leq n - r, 1 \leq j \leq n} & 0 \end{pmatrix}.
\]

Clearly, we have \( \det \tilde{M} = C \det M \), where \( C = (-1)^{\sum Q_i} q^{-\sum (Q_j+1)} \). We decompose the matrix \( \tilde{M} \) as a product of two (infinite) matrices
\[
\tilde{M} = \begin{pmatrix} 0 & \left( (-1)^a q^{a+1} a_{1 \leq i \leq m, a \geq 0} \right) \\ (\delta_{a-1, P_i}) a_{1 \leq i \leq n - r, a < 0} & 0 \end{pmatrix} \begin{pmatrix} (q^N a_{a \in \mathbb{Z}, 1 \leq j \leq n} \quad ((-1)^Q_j \delta_{a, Q_j}) a_{a \in \mathbb{Z}, 1 \leq j \leq m - r}) \\ 0 \end{pmatrix},
\]

Now we apply the Cauchy–Binet formula, the numbers of columns in the minor from the first factor (the numbers of rows in the minor from the second factor) we denote by \(-P_1, \ldots, -P_{n-r} - 1, A_1, \ldots, A_r, Q_1, \ldots, Q_{m-r} \), and get
\[
\det M = (-1)^{(m-r)(n-r)} \sum_{A_1 > A_2 > \ldots > A_r \geq 0} \left( \sum_{i=1}^{r} A_i \right) a_N(q^{A_i} q^{P-1}) a_M(q^{-A}, q^{-Q})
\]

Therefore we proved that the right sides of (2.3) and (2.4) are equal. \( \square \)
4. Integer Points in Polyhedra

4.1. In this section we give a combinatorial proof of Theorem 3. The proof is based on Brion’s theorem which we briefly recall. Standard references for this theorem are [6, 32, 33, 29], for a clear introduction see, for example, [3].

Let $P \subset \mathbb{R}^N$ be a convex polyhedron, i.e., an intersection of a finite number of half-spaces. Note that $P$ can be unbounded. For simplicity we assume below that vertices of $P$ have integer coordinates and edges have rational directions.

For a point $p = (p_1, \ldots, p_N) \in \mathbb{Z}^N$ by $t^p$ we denote $t_1^{p_1} \cdots t_N^{p_N}$, where $t_1, \ldots, t_N$ are formal variables. Define the characteristic function of $P$ by the formula

$$ S(P) = \sum_{p \in P \cap \mathbb{Z}^N} t^p. $$

In this definition $S(P)$ is a formal series, $S(P) \in \mathbb{Z}[\![t_1^{\pm 1}, \ldots, t_N^{\pm 1}]\!]$. It can be proven that there exist two Laurent polynomials $f, g \in \mathbb{Z}[\![t_1^{\pm 1}, \ldots, t_N^{\pm 1}]\!]$ such that $fS(P) = g$ (see e.g. [2, Theorem 13.8]). We denote $S(P) = f/g \in \mathbb{Q}(t_1, \ldots, t_n)$. Clearly $S(P)$ does not depend on the particular choice of $f, g \in \mathbb{Z}[\![t_1^{\pm 1}, \ldots, t_N^{\pm 1}]\!]$.

For any vertex $v \in P$, we denote by $K_v$ its cone, i.e., the intersection of half-spaces corresponding to the facets (maximal proper faces) of $P$ containing $v$.

**Theorem** (Brion). For any convex polyhedron $P$ with integer vertices and rational directions of edges we have

$$ S(P) = \sum_v S(K_v). $$

Plane partitions satisfying (1.1) and (1.2) are integer points of the polyhedron $P_{\mu,\nu,\lambda}^{n,m}$ in the space with coordinates $t_{i,j} (i, j) \in \mathbb{N}^2 \setminus \lambda$. The polyhedron $P_{\mu,\nu,\lambda}^{n,m}$ defined by the inequalities

$$ P_{\mu,\nu,\lambda}^{n,m} : \begin{cases} t_{i,j} \geq t_{i,j+1} & t_{i,j} \geq \nu_i \geq 0, \\ t_{i,j} \geq t_{i+1,j} & t_{i,j} \geq \mu_j \geq 0, \\ t_{n+1,m+1} = 0 \end{cases} \quad (4.1) $$

Therefore the functions $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ can be computed using Brion theorem.

Two remarks are in order. First, we stated Brion theorem for finite dimensional polyhedra, but $P_{\mu,\nu,\lambda}^{n,m}$ is infinite dimensional. Therefore we start from the finitization of $P_{\mu,\nu,\lambda}^{n,m}$, i.e., for $H, H' \in \mathbb{N}$ we consider the polyhedron $P_{\mu,\nu,\lambda}^{n,m,H,H'}$ defined as

$$ P_{\mu,\nu,\lambda}^{n,m,H,H'} : \begin{cases} t_{i,j} \geq t_{i,j+1} & t_{i,H} = \nu_i \geq 0, \\ t_{i,j} \geq t_{i+1,j} & t_{H,j} = \mu_j \geq 0, \\ t_{n+1,m+1} = 0 \end{cases}, \quad (i, j) \in \{1, \ldots, H'\} \times \{1, \ldots, H\} \setminus \lambda. \quad (4.2) $$

We compute $S(P_{\mu,\nu,\lambda}^{n,m,H,H'})$ and then take the limit $H, H' \to \infty$.

Second, we need a specialization of the function $S(P)$ in which $t_{i,j} \to q$. We denote by $S_q(P) \in \mathbb{Q}(q)$ the function obtained by composition of $S$ and this specialization. The limit $\lim_{H, H' \to \infty} q^{-\Delta^{H,H'}} S_q(P_{\mu,\nu,\lambda}^{n,m,H,H'})$ coincides with $\chi_{\mu,\nu,\lambda}^{n,m}(q)$. Here the numbers $\Delta^{H,H'}$ emerge due to different definitions of grading, see below.
It will be convenient to start from a specialization \( t_{i,j} \to x_{j-i+1}/x_{j-i} \). We denote by \( S_x(P) \in \mathbb{Q}(\{x_i\}) \) composition of \( S \) and this specialization. Then we can set \( x_i \to q^i \) and get \( S_q(P) \).

4.2. We explain main ideas in the case \( m = 0 \). As the result we get a new proof of (1.4).

We will work under additional assumption of strict inequalities \( \nu_1 > \ldots > \nu_n \), in the Section 4.4 we briefly explain (following [34]) how to remove this assumption.

We start from a description of vertices of the polyhedron \( P_{\varnothing,\mu,\nu,\lambda} \). Since \( t_{n+1,1} = 0 \) one can think that indices \((i, j)\) of coordinates \( t_{i,j} \) satisfy \( 1 \leq i \leq n, 1 \leq j \leq H, (i, j) \notin \lambda \), i.e. \((i, j)\) lies in a skew Young diagram that we will denote \((H_n) - \lambda\). Any face of our polyhedron is defined by (4.2) where some of the inequalities become equalities. For any face we construct a graph \( \Gamma \) with vertices \((i,j)\) satisfying conditions above. Two vertices \((i,j)\) and \((i',j')\) are connected by an edge iff \( t_{i,j} = t_{i',j'} \) for all points of the face and boxes \((i,j)\) and \((i',j')\) have a common side.

There exist at least \( n \) connected components in \( \Gamma \) since \( t_{i,H} = \nu_i \) and \( \nu_i > \nu_j \) for \( i > j \). Vertices of our polyhedron are faces of maximal codimension, i.e., corresponding to graphs having exactly \( n \) connected components. See an example in Fig. 7.

![Figure 7](image-url)

Denote by \( \Gamma_v \) the graph corresponding to the vertex \( v \). Denote by \( K_s \) connected components of \( \Gamma_v \). Each \( K_s \) is a skew Young diagram. Denote by \( \mathcal{K}_{s,v} \) projection of the cone \( \mathcal{K}_v \) on the subspace with coordinates \( t_{i,j} \) for \((i,j) \in K_s \). Then we have \( S(\mathcal{K}_v) = \prod S(\mathcal{K}_{s,v}) \).

Situation simplifies since for many vertices \( S_q(\mathcal{K}_v) \) vanishes due to the following result.

**Proposition 4.1** ([34 Theorem 2.1]). If the connected component \( K_s \) has cycles, then \( S_x(\mathcal{K}_{s,v}) \) is equal to 0.

In particular, from this Proposition and calculation in acyclic case below follows that specializations \( S_q(\mathcal{K}_v) \) (and therefore \( S_q(P_{\varnothing,\mu,\nu,\lambda}^{n,0,(H,H')}) \)) are well defined.

Therefore by Brion theorem we have

\[
S_q(P_{\varnothing,\mu,\nu,\lambda}^{n,0,(H,H')}) = \sum_v S_q(\mathcal{K}_v),
\]

(4.3)

where the summation goes over the vertices \( v \) such that corresponding graphs \( \Gamma_v \) are acyclic.

Recall that a skew Young diagram \( \alpha - \beta \) is a called ribbon if it is connected and contains no \( 2 \times 2 \) block of squares. Due to Proposition 4.1 vertices of \( P_{\varnothing,\mu,\nu,\lambda}^{n,0,(H,H')}(\mathbb{C}) \) with
nonzero contribution correspond to decompositions of the skew diagram \((H^n) - \lambda\) into \(n\) ribbons such that boxes \((i, H)\) belong to different ribbons.\(^2\)

In order to discuss ribbons it is convenient to use also another combinatorial description. For any partition \(\lambda\) we assign sequence of numbers \(\lambda_i - i\). This maps is the bijection between partitions and sequences \(\{a_i | i \in \mathbb{Z}_{>0}\}\) such that \(a_i > a_{i+1}\) and \(a_i = -i\) for \(i >> 0\). We will say that there are particles in the points \(\lambda_i - i\) and holes on other integer points. For the illustration see Fig. 3, black balls are particles, white balls are holes (up to total shift by \(\frac{1}{2}\)).

The following lemma is standard

**Lemma 4.1.** Skew partition \(\alpha - \beta\) is a ribbon if and only if there exist \(j, k \in \mathbb{N}\) such that the set \(\{\alpha_i - i\}\) is obtained from the set \(\{\beta_i - i\}\) by replacement of \(\beta_j - j\) by \(\beta_j - j + k\).

We will call such replacement \(\beta_j - j\) by \(\beta_j - j + k\) as jump of the particle \(\beta_j - j\). Therefore, in a more informal language the lemma means that a jump of one particle to the right corresponds to the addition of the ribbon to partition. The decomposition of skew partition on \(n\) ribbon corresponds to the sequence of \(n\) jumps of particles.

Assume that \(H > \lambda_1 + n - 1\). Then the sets of particles for partitions \((H^n)\) and \(\lambda\) differ in the first \(n\) numbers. Therefore to any decomposition of the skew diagram \((H^n) - \lambda\) into \(n\) ribbons we assign a permutation \(\sigma \in S_n\) such that corresponding jumps are from \(\lambda_i - i\) to \(H - \sigma(i)\). Since the boxes \((i, H)\) belong to different ribbons the order of jumps is is unique: first jump goes to \(H - 1\), second to \(H - 2\) and so forth. On the other side to any permutation we assign the sequence of jumps due to "only if" part of the Lemma 4.1 get a decomposition of skew diagram \((H^n) - \lambda\) into \(n\) ribbons such that boxes \((i, H)\) belong to different ribbons.

So we get a a one-to-one correspondence between acyclic graphs \(\Gamma_v\) and permutations. For example the graph \(\Gamma_v\) in the Fig. 8 corresponds to the permutation \((1\ 2\ 3\ 4)\) (1 4 3 2).

\[\text{Figure 8.}\]

We denote by \(v_\sigma\) the acyclic vertex corresponding to \(\sigma \in S_n\).

**Lemma 4.2.** For the vertex \(v_\sigma\) of the polyhedron \(P_{\phi, \nu, \lambda}^{n, H, H'}\) we have

\[S_q(K_{v_\sigma}) = (-1)^{|\sigma|} q^{\Delta_{\phi, \nu, \lambda}(H, H')} \prod_{i=1}^{n} (q)^{H - \sigma(i) - \lambda_i + i - 1}, \tag{4.4}\]

\(^2\)One can compare this to Murnaghan–Nakayama rule.
where \((q)_k = \prod_{s=1}^{k}(1-q^s)\) and
\[
\Delta^{\sigma,H}(\lambda, \nu) = \sum_{i=1}^{n}(H\nu_i - i\lambda_i - i\nu_i + i^2) - \sum_{i=1}^{n}(\lambda_i - i)(\nu_{\sigma(i)} - \sigma(i))
\]

The proof is similar to the one in [34, Prop. 2.4].

**Proof.** Let \(K_i\) be the ribbon which corresponds to particle jump from \(\lambda_i - i\) by \(H - \sigma(i)\). The set \(\{K_i\}\) is a set of all connected components of the graph \(\Gamma_{v_s}\). First, we compute the contribution of the corresponding cone \(S(K_{v_s,v_s})\).

Denote by \(h\) the number of boxes in the ribbon \(K_i\), clearly \(h = H - \sigma(i) - \lambda_i + i\). We number these boxes by \(1, \ldots, h\) from the bottom-left corner to the top-right corner. In order to simplify notation we denote the corresponding coordinates \(t_{ij}\) by \(t_1, \ldots, t_h\). In the vertex \(v_i\) of cone \(K_{v_s,v_s}\) all these coordinates equal \(\nu_{\sigma(i)}\), therefore \(S_q(t^n) = q^{\nu_{\sigma(i)}h}\).

The cone \(K_{v_s,v_s}\) is simple. Its edges are generated by the vectors \(e_1, \ldots, e_{h-1}\), where the vector \(e_s\) equals \(\pm (1, \ldots, 1, 0, \ldots, 0)\), with \(s\) nonzero coordinates. The sign \(\pm\) is equal to \(\pm\) if the box \(s + 1\) is right neighbor of the box \(s\) and is equal to \(\mp\) if the box \(s + 1\) is upper neighbor of the box \(s\). See an example in Fig. 9

![Figure 9](image-url)

Therefore \(S_q(K_{v_s,v_s}) = q^{\nu_{\sigma(i)}h} / \prod_{s=1}^{h-1}(1-q^{s\pm 1})\), where the signs \(\pm\) were specified above.

Now we want to express this product in more explicit terms.

**Lemma 4.3.** The box \(s + 1\) is upper neighbor of the box \(s\) then there exist \(j\) such that \(i > j\), \(\sigma(i) < \sigma(j)\) and \(s = \lambda_j - j - \lambda_i + i\)

In terms of particles this lemma means that particle \(\lambda_i - i\) in its jump overtakes the particle \(\lambda_j - j\) and \(s\) in lemma corresponds to overtaking place.

**Proof of the Lemma.** We draw lines given by equations \(y = x + c\), where \(c \in \mathbb{Z}\). Such lines go through centers of boxes in our skew diagram \((H^n) - \lambda\). Such a line intersects the ribbon \(K_i\) in one box if \(\lambda_i - i + 1 \leq c \leq H - \sigma(i)\) and does not intersect otherwise.

If the box \(s + 1\) is upper neighbor of the box \(s\) then, the right neighbour of the box \(s\) belong to another ribbon. Denote this ribbon by \(K_{v'}\) and let this box (right neighbor of the box \(s\)) has the number \(s' + 1\) in the ribbon \(K_{v'}\).

If \(s' > 0\) then there is a previous box in the ribbon \(K_{v'}\). This box has number \(s'\) in \(K_{v'}\) and should be the lower neighbor of the box \(s' + 1\). And again, the right neighbor should belong to another ribbon, denote this ribbon by \(K_{v''}\) and let this box has the number
We can find $S_q(K_{v,i})$ by using formula (2.1) with the weight defined in formula (2.1) for $q = 1$. Since this line goes through the center of the first box on $K_j$, we have $c = \lambda_j - j + 1$. Therefore $s = \lambda_j - j - \lambda_i + i$. In such case $\sigma(i) < \sigma(j)$ since $K_j$ is below $K_i$, but $i > j$ since $s > 0$.

See the Figure 5 for the demonstration of this effect.

Conversely, for any $j$ such that $j > i$ and $\sigma(j) < \sigma(i)$ consider the first box of $K_j$. The line $y = x + c$ for $c = \lambda_j - j + 1$ goes through the center of this box and should intersect the ribbon $K_i$. Let the box of intersection has number $s + 1$ in $K_i$. Since $\sigma(i) < \sigma(j)$ the ribbon $K_i$ is higher then the ribbon $K_j$ and the box $s + 1$ in $K_i$ is higher then the first box in the ribbon $K_j$. The box $s + 1$ in $K_i$ cannot be the first box of the ribbon since $\lambda_i - i \neq \lambda_j - j$. And it is easy to prove similarly to the previous paragraphs that the box number $s$ is low neighbor of the box $s + 1$. □

Rewriting factors $1 / (1 - q^{-s})$ as $-q^s / (1 - q^s)$ and using formula for $h$ we have

$$S_q(K_{v,i}) = (-1)^{|\{j < i, \sigma(j) > \sigma(i)\}|} q^{\nu_{\sigma(i)}(H - \sigma(i) - \lambda_i + i)} \prod_{s=1}^{H - \sigma(i) - \lambda_i + i - 1} (1 - q^s)$$

Now we can find $S_q(K_{v,i}) = \prod_{i=1}^{n} S_q(K_{v,i})$. Using algebraic identities

$$\sum_{j < i, \sigma(j) > \sigma(i)} (\lambda_j - j - \lambda_i + i) = \sum_{i=1}^{n} (\lambda_i - i)(\sigma(i) - i)$$

and

$$\sum_{i=1}^{n} \nu_{\sigma(i)}(H - \sigma(i) - \lambda_i + i) + \sum_{i=1}^{n} (\lambda_i - i)(\sigma(i) - i) = \Delta_{\sigma,H}(\lambda, \nu)$$

we get (4.4). □

Now we can find $S_q(P^{n,0}_{\mathcal{E},\mu})$ using specialization of Brion theorem (4.3)

$$S_q(P^{n,0}_{\mathcal{E},\mu}) = \sum_{\sigma \in S_n} (-1)^{|\sigma|} q^{S_{\sigma,H}(\lambda, \nu)} \prod_{i=1}^{n} (q^{H - \sigma(i) - \lambda_i + i - 1})$$

Here we count integer points in $P^{n,0}_{\mathcal{E},\mu}$ with the weight $q^{\sum_{i,j} \nu}$, which differs from the weight defined in formula (2.1) by $q^{\Delta(H)}$, where $\Delta(H) = \sum_{i=1}^{n} \nu_i(\lambda - \lambda_i)$. Using identity

$$\Delta_{\sigma,H}(\lambda, \nu) - \Delta(H) = \sum_{i=1}^{n} (\nu_i + n - i)(\lambda_i + n - i) - \sum_{i=1}^{n} (\lambda_i + n - i)(\nu_{\sigma(i)} + n - \sigma(i))$$

we see that limit $\lim_{H \to \infty} q^{\Delta(H)} S_q(P^{n,0}_{\mathcal{E},\mu})$ coincides with the right side of (1.4).

4.3. In this subsection we prove Theorem 3 under the assumption

$$\nu_1 > \ldots > \nu_n > \mu_1 > \ldots > \mu_m$$

The Theorem 3 is valid without this assumption and later, in subsection 4.4 we explain this.
Proof. As before for any vertex \( v \) we construct the graph \( \Gamma_v \). It follows from Proposition [4.4] that vertices with nonzero contribution in \( S_q \) correspond to decompositions of skew diagram \( (H^n, m^{H^n-n}) - \lambda \) into \( m + n \) ribbons (connected components of \( \Gamma_v \)), where \( n \) contain boxes \( (i, H) \), \( 1 \leq i \leq n \), and \( m \) contain boxes \( (H', j) \), \( 1 \leq j \leq m \).

For any partition \( \alpha \) we consider the set of particles in coordinates \( \{\alpha_i - i + n - m + 1\} \). Note that this set differs from the one used in Lemma [4.1] by \( n - m + 1 \).

We recall notation from Section [2] \( \{L_i = \lambda_i - i + n - m + 1\} \) and \( L_i = P_i + 1 \), for \( 1 \leq i \leq n - r \), \( L_i \leq 0 \) for \( i > n - r \). The set of particles for \( (H^n, m^{H^n-n}) \) equals

\[
\{H+n-m, \ldots, H-m+1, 0, \ldots, -H'+n+1, -H'+n-m, \ldots\}. \tag{4.7}
\]

Ribbons which contains the boxes \( (i, H) \) corresponds to the jumps of particles to the points \( H+n+1-i, 1 \leq i \leq n \). Ribbons which contains the boxes \( (H', j) \) corresponds to the jumps from points \( -H'+n-m+j, 1 \leq j \leq m \). The order of such jumps in uniquely specified by the inequality (4.6): first jumps to \( H+n, \ldots, H+n-m+1 \) then jumps from \( -H'+n-m+1, \ldots, -H'+n \).

Due to Lemma [4.3] the first \( n \) jumps should starts from numbers \( B_1 > B_2 > \ldots > B_n \), \( B_i \in \{L_s | s \in \mathbb{N}\} \). Assume that \( H > \lambda_1 + n - 1 \), then there are \( n - r \) particles for \( \lambda \) in \( P_i + 1 \) which are not present in (4.7). Therefore the numbers \( P_i + 1 \) should belong to the set \( \{B_i\} \), in other words

\[
(B_1, B_2, \ldots, B_n) = (P_1 + 1, \ldots, P_{n-r} + 1, -A_r, \ldots, -A_1), \tag{4.8}
\]

where \( A_i \in \{-L_s | s > n - r\} \). For any vertex we assign a permutation \( \sigma \in S_n \) such that our \( n \) ribbons replace \( B_i \) by \( H+n-m+1-\sigma(i) \). These data \( \sigma \in S_n \) and \( \{A_i | 1 \leq i \leq r\} \in \{-L_s | s > n - r\} \) encode \( n \) ribbons containing \( (i, H) \).

Due to Lemma [2.5] the set \( \{L_i\} \) has \( m - r \) non-positive holes in integers \(-Q_j\). Assume that \( H' > \lambda_1' + m - 1 \), then these holes are occupied in (4.7). And adding first \( n \) ribbons we have \( r \) additional holes in \(-A_1, \ldots, -A_r\). Therefore the last \( m \) jumps should go the the numbers \(-C_j\), where

\[
(C_1, C_2, \ldots, C_m) = (Q_1, \ldots, Q_{m-r}, A_1, \ldots, A_r). \tag{4.9}
\]

Introduce permutation \( \tau \) such that jumps goes from \(-H'+n-m+\tau(j)\) by \(-C_j\). This permutation encodes the last \( m \) jumps. In order to construct inverse map we apply "only if" part of the Lemma [4.1] and this works only under restriction that \( H'-n-m-\tau(m+j) > A_j \).

We will call such \( \tau \) admissible. Below we go to the limit \( H' \to \infty \), in this limit given set of \( A_i \) do not impose any restriction of the permutation \( \tau \).

We denote by \( v_{\sigma, \tau, A} \) the corresponding vertex. In the example in Fig. [10] we have \( \sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 3 & 4 & 2 \end{pmatrix} \), \( \tau = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix} \), \( A_1 = 2, A_2 = 0 \).

Therefore by Brion theorem we have

\[
S_q(P_{\mu, \nu, \lambda}^{n,m}(H,H')) = \sum_{\sigma, \tau, A} S_q(K_{v_{\sigma, \tau, A}}), \tag{4.10}
\]

where \( \sigma \in S_n, A_i = -L_{s_i} \), for \( s_1 > \cdots > s_r > n - r \) and \( \tau \in S_m \) is admissible.
Lemma 4.4. For the vertex $v_{\sigma,\tau,A}$ of the polyhedron $P^{n,m,(H,H')}_{\mu,\nu,\lambda}$ we have

\[
S_q(K_{v_{\sigma,\tau,A}}) = \frac{(-1)^{|\sigma|+|\tau|+\sum(A_i-i+1)} q^\Delta_{\sigma,\tau,A,(H,H')}^\mu_{\nu,\lambda}}{\prod_{i=1}^n (q^H-\sigma(i)+n-m-B_i) \prod_{j=1}^m (q^H'-\tau(j)+m-n-C_j-1)},
\]

(4.11)

where

\[
\Delta_{\sigma,\tau,A,(H,H')}^\mu_{\nu,\lambda} = \sum_{i=1}^r A_i \left( \frac{A_i+1}{2} - N_{\sigma(n-i+1)} + M_{\tau(m-r+i)} \right) + \sum_{i=1}^{n-r} (P_i+1)(-N_{\sigma(i)}+n-i) + \sum_{j=1}^{m-r} Q_j(-M_{\tau(j)}+m-j) + \sum_{i=1}^n \nu_i(H+n-m-i+1) + \sum_{j=1}^m \mu_j(H'+n-m-j)
\]

(4.12)

and $N_i = \nu_i + n - i$, $M_j = \mu_j + m - j$.

Proof. The proof of this lemma is analogous to the one of Lemma 4.2. In the denominator we have a product of $(q)_{h-1}$ where $h$ is the length of the ribbon. The power of $q$ in the numerator is made from two summands. The first one

\[
\sum_{i=1}^n \nu_{\sigma(i)}(H-\sigma(i)+n-m)+1-B_i + \sum_{j=1}^m \mu_{\tau(j)}(H'-\tau(j)+m-n-C_j)
\]

is the sum of the weights of the vertices $v_i$ in cones $K_{v_{\sigma,\tau,A,i}}$ corresponding to ribbons. The second one comes from rewriting $1/(1-q^{-s})$ as $-q^s/(1-q^s)$. Such terms come from the edges of the form $-(1,\ldots,1,0,\ldots,0)$ as in Lemma 4.2.
It was explained in the proof of Lemma 4.2 that for ribbons which contain boxes \((i, H)\) such terms corresponds the pairs of consecutive boxes \(s, s + 1\) such that \(s + 1\) is upper neighbor of the box \(s\). For ribbons which contain boxes \((H', j)\) situation is reflected, if we number boxes from upper right corner then such terms corresponds the pairs of consecutive boxes \(s, s + 1\) such that \(s + 1\) is a lower neighbor of the box \(s\).

Moreover, it was explained in the proof of the Lemma 4.3 that such terms corresponds to the overtaking of the particles, and the corresponding overtakings give the terms \(\sum_{i=1}^{n} B_i(\sigma(i) - i)\) and \(\sum_{j=1}^{m} C_j(\tau(j) - j)\) (compare with (4.5)). Now for ribbons which contain boxes \((i, H)\) we have an additional phenomena, namely the particles overtakes standing particles in nonpositive positions \((0, \ldots, -H + n + 1)\) (except particles in position \(-A_j\), for \(j > i\)). In terms of the proof the Lemma 4.3 it means that the line \(y = x - n + m + c\) for \(c < 0\), can intersect not the first box of another ribbon but vertical border of the diagram \((H^n, m^{H'-n})\). For each \(1 \leq i \leq r\) this gives the term \(\sum_{s=1}^{A_1} s - \sum_{j=i+1}^{r} (A_i - A_j)\). The resulting formula is

\[
\sum_{i=1}^{r} \left( A_i + 1 \right) \left( r - i + 1 \right) + \sum_{i=1}^{r} A_i (r - i + 1) + \sum_{i=1}^{n} B_i(\sigma(i) - i) + \sum_{j=1}^{m} C_j(\tau(j) - j).
\]

Putting all things together and using (1.8), (1.9) we get (1.12).

Now we find \(\lambda_{\mu, \nu, \lambda}(q)\) as \(\lim_{H, H' \to \infty} q^{-\Delta(H, H')} S_q(p_{\mu, \nu, \lambda}(H, H'))\), where

\[
\Delta(H, H') = \sum_{i=1}^{n-r} \nu_i(H - P_i - i + n - m) + \sum_{j=1}^{m-r} \mu_j(H' - Q_j - j + m - n)
\]

\[
+ \sum_{i=n-r+1}^{n} \nu_i(H - i + n - m + 1) + \sum_{j=m-r+1}^{m} \mu_j(H' - j + m - n).
\]

It is easy to see that \(\Delta_{\sigma, \tau, \lambda}(H, H')(\mu, \nu, \lambda) - \Delta(H, H') = \Delta_{\tilde{\sigma}, \tilde{\tau}, A}(\mu, \nu, \lambda)\) for

\[
\tilde{\sigma} = \sigma \circ \begin{pmatrix} 1 & \ldots & r & r + 1 & \ldots & n \\ n & \ldots & n - r + 1 & 1 & \ldots & n - r \end{pmatrix}, \quad \tilde{\tau} = \tau \circ \begin{pmatrix} 1 & \ldots & r & r + 1 & \ldots & m \\ m - r + 1 & \ldots & m & 1 & \ldots & m - r \end{pmatrix}
\]

and we get formula (2.6).

4.4. In the previous subsection we proved Theorem 3 under the assumption (4.6)

\(\nu_1 > \ldots > \nu_n > \mu_1 > \ldots > \mu_m\).

But this theorem holds for any \(\nu, \mu\) since it is equivalent to Theorem 1 proven in section 3.

In this subsection we explain how to get rid of the condition (4.6) in the context of Brion theorem.

First, note that if some inequalities between \(\nu_i, \mu_j\) become equalities then the polyhedron \(P_{\mu, \nu, \lambda}(H, H')\) degenerates. This degeneration changes combinatorial structure, in particular, some of the vertices merge. But one can ignore this when using Brion theorem (see arguments in [18 Sec. 8]). Therefore Theorem 3 still holds.

Now fix any strong order \(\sigma\) on \(\{\nu_1, \ldots, \nu_n, \mu_1, \ldots, \mu_m\}\) such that \(\nu_{i_1} > \nu_{i_2}, \mu_{j_1} > \mu_{j_2}\) for \(i_1 < i_2\) and \(j_1 < j_2\). Proposition 4.4 implies that vertices with nonzero contribution to
$S_q(P_{\mu, \nu, \lambda}^{n,m,(H,H')})$ correspond to decompositions of the skew diagram $(H^n, m^{H'-n}) - \lambda$ into $m + n$ ribbons (of which $n$ contain boxes $(i, H)$, $1 \leq i \leq n$, and $m$ contain boxes $(H', j)$, $1 \leq j \leq m$).

The order $\sigma$ provides additional condition on such decomposition. The usual partial order on boxes ($b_i \geq b_j$ if $b_i$ lies to the northwest of $b_j$) induces a partial order on ribbons: $K_i \geq K_j$ if there are boxes $b_i \in K_i$, $b_j \in K_j$ such that $b_i \geq b_j$. Such order should be compatible with the order $\sigma$ if we identify ribbons containing $(i, H)$ with $\nu_i$ and ribbons containing $(H', j)$ with $\mu_j$.

The set of vertices depends on the order $\sigma$. But the contribution of a vertex is a product of ribbon contributions, and each such contribution is defined for any $\nu_i$ and $\mu_j$ (not necessarily compatible with $\sigma$).

So for any given order $\sigma$ the function $S_q(P_{\mu, \nu, \lambda}^{n,m,(H,H')})$ computed using Brion theorem is defined for any nonnegative integer numbers $\nu_i$, $\mu_j$ not necessarily compatible with $\sigma$.

For any given $n, m, \mu, \nu, \lambda$ we denote this function just by $S_{\sigma}^{(H,H')}(q)$ and its limit (as $H, H' \to \infty$) as $S_{\sigma}(q)$.

**Example 4.1.** Let $n = m = 1$, $\lambda = \emptyset$. We have two possible orders $\sigma$: $\nu_1 > \mu_1$ and $\sigma'$: $\mu_1 > \nu_1$. For $\sigma$ we have $H' - 1$ vertices and using Brion Theorem we obtain

$$S_{\sigma}^{(H,H')}(q) = \sum_{a=0}^{H'-2} (-1)^a q^{(a+1)/2} q^{(H+a)\nu_1 + (H'-a-1)\mu_1} \frac{q^{H+a-1}(q) H'-a-2}{(q)_{H-a-1}(q)_{H'-a-2}}.$$

For the order $\sigma'$ we have $H - 1$ vertices and using Brion Theorem we obtain

$$S_{\sigma'}^{(H,H')}(q) = \sum_{b=0}^{H-2} (-1)^b q^{(b+1)/2} q^{(H-b-1)\nu_1 + (H'+b)\mu_1} \frac{q^{H-b-2}(q)_{H'-b-1}}{(q)_{H-b-2}(q)_{H'-b-1}}.$$

**Figure 11.** Some examples of decompositions and compatible orders
These formulas are different, they even have different number of summands. Brion theorem proves that the first formula calculates $S_2^2 M$. Bershtein, B. Feigin, G. Merzon

It is convenient to rewrite the last inequality as

$$\text{Proof.} \text{It is enough to consider the case when } H, H' \text{ is large enough}$$

If $\nu_1 - \mu_1 + H' - 2 \leq H + H' - 4$.

It is convenient to rewrite the last inequality as

$$2 - H' \leq \nu_1 - \mu_1 \leq H - 2,$$  \hspace{1cm} (4.13)

in this region both formulas give the same (and therefore correct) answer.

In the limit $H, H' \to \infty$ situation becomes simpler. Indeed, for any given $\nu_1, \mu_1$ and large enough $H, H'$ the inequality (4.13) is satisfied and in the limit $S_\sigma(q) = S_{\sigma'}(q)$.

Now we prove generic

**Proposition 4.2.** If $n + 1 - H' \leq \nu_i - \mu_j \leq H - m - 1$ for any $i, j$ then for any two orders $\sigma, \sigma'$ we have

$$S_\sigma(H, H')(q) = S_{\sigma'}(H, H')(q).$$

**Proof.** It is enough to consider the case when $\sigma, \sigma'$ differ only by an elementary transposition of $\nu_i$ and $\mu_j$ (in $\sigma : \nu_i > \mu_j$ and $\sigma' : \mu_j > \nu_i$). Recall that the summands in $S_\sigma(H, H')(q)$ and $S_{\sigma'}(H, H')(q)$ correspond to decompositions of the skew diagram $(H^n, m^{H' - n}) - \lambda$ into $m + n$ ribbons compatible with orders $\sigma$ and $\sigma'$ correspondingly. There are three possibilities.

Case 1. Ribbons containing boxes $(i, H)$ and $(H', j)$ have no common edges. Corresponding summands appear both in $S_\sigma(H, H')(q)$ and $S_{\sigma'}(H, H')(q)$.

Case 2. Union of ribbons containing boxes $(i, H)$ and $(H', j)$ is a ribbon. Denote this ribbon by $\alpha - \beta$. Fix ribbons containing other end-boxes $(i', H)$ and $(H', j')$ for $i' \neq i$ and $j' \neq j$. For such summands $\alpha - \beta$ is divided by an internal edge $e$ into two ribbons containing $(i, H)$ and $(H', j)$. Denote by $S_{e, \alpha - \beta}(q)$ the product of contributions of these two ribbons. If the edge $e$ is horizontal then the corresponding term appears in $S_\sigma(H, H')(q)$, otherwise in $S_{\sigma'}(H, H')(q)$.

**Lemma 4.5.** Suppose $\alpha - \beta$ is a ribbon such that $\alpha - \beta$ lies in the rectangle $H \times H'$ and contains boxes $(i, H)$ and $(H', j)$. If $1 + i - H' \leq \nu_1 - \mu_1 \leq H - j - 1$ then

$$\sum_{e: \text{horizontal}} S_{e, \alpha - \beta}(q) = \sum_{e: \text{vertical}} S_{e, \alpha - \beta}(q)$$

This lemma is a generalization of Example 4.1 and by straightforward calculation reduces to the $q$-binomial theorem. Due to this lemma the contributions to $S_\sigma(H, H')(q)$ and $S_{\sigma'}(H, H')(q)$ are equal to each other in this case.
Example 4.2. Consider $\alpha = (4, 2, 1, 1)$ and $\beta = (1)$. In this case $\alpha - \beta$ has 6 internal edges, corresponding decompositions are drawn below in Fig. 12 The terms $S_1, S_2, S_4$ correspond to the horizontal internal edges $e$ and order $\nu_1 > \mu_1$. The terms $S_3, S_5, S_6$ correspond to the vertical internal edges $e$ and order $\mu_1 > \nu_1$. We have

$$S_1 + S_2 - S_3 + S_4 - S_5 - S_6 = \frac{q^{\mu_1 + 6\nu_1 + 4}}{(q)_6} - \frac{q^{2\mu_1 + 5\nu_1 + 2}}{(q)(q)_5} + \frac{q^{3\mu_1 + 4\nu_1 + 1}}{(q)_4} - \frac{q^{4\mu_1 + 3\nu_1 + 1}}{(q)_4(q)_3} + \frac{q^{5\mu_1 + 2\nu_1 + 2}}{(q)_5(q)_1} - \frac{q^{6\mu_1 + \nu_1 + 4}}{(q)_6} = \prod_{i=1}^{5} (1 - q^{\mu_1 - \nu_1 - 3 + i})$$

So in other words we get zero for $-2 \leq \nu_1 - \mu_1 \leq 2$ as in Lemma 4.5.

Case 3. Union of ribbons containing boxes $(i, H)$ and $(H', j)$ is a connected skew Young diagram $\alpha - \beta$ but not a ribbon. Informally it means that $\alpha - \beta$ has width 2 in the middle. In this case there are two ways to decompose $\alpha - \beta$ into two ribbons. Corresponding two terms are equal to each other, and one goes to $S_6^{(H,H')}(q)$ and other to $S_6^{(H,H')}(q)$. □

Remark 4.1. The calculation in Case 3 is essentially the last step in the proof of [34, Theorem 2.1] (see our Proposition 4.1).

Tending $H, H' \to \infty$ we get from Proposition 4.2 that the function $S_6(q)$ does not depend on the order $\sigma$. For the actual order of $\nu_1, \mu_j$ this function coincides with $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ and for the order (4.6) this function coincides with right side of (2.6).

5. Algebras, representations and resolutions

5.1. For the reference of quantum toroidal algebra $U_{\overline{q}}(\hat{g}_1)$ one can use [44, Sec. 2], but our notation slightly differs from the loc. cit.

Fix complex numbers $\epsilon_i$, where $i = 1, 2, 3$ and should be viewed as mod 3 residues. We assume that $\epsilon_1 + \epsilon_2 + \epsilon_3 = 0$. Denote $q_i = e^{\epsilon_i}$, $\overline{q} = (q_1, q_2, q_3)$. We assume further that $q_1, q_2, q_3$ are generic, i.e., for integers $l, m, n \in \mathbb{Z}$, $q_1^l q_2^m q_3^n = 1$ holds only if $l = m = n$. We set

$$g(z, w) = \prod_{i=1}^{3} (z - q_i w), \quad \kappa_r = \prod_{i=1}^{3} (q_i^{r/2} - q_i^{-r/2}) = \sum_{i=1}^{3} (q_i^r - q_i^{-r}), \quad \delta(z) = \sum_{m \in \mathbb{Z}} z^m.$$

Currently there is no standard convention to the notation, even for the algebra itself other names $\mathcal{E}$, $\mathcal{E}_1$, $\mathcal{S}_H$, $U_{\overline{q}}(q_1, q_2, q_3)(\hat{g}_1)$ are also used in the literature.
The algebra $U_q(\tilde{\mathfrak{gl}}_1)$ is generated by $E_m, F_m, H_r$, where $m \in \mathbb{Z}, r \in \mathbb{Z} \setminus 0$ and invertible central elements $C, C^\perp$. In order to write down the defining relations we form the currents (generating functions of operators)

$$E(z) = \sum_{m \in \mathbb{Z}} E_m z^{-m}, \quad F(z) = \sum_{m \in \mathbb{Z}} F_m z^{-m}, \quad K^\pm(z) = (C^\perp)^{\pm1} \exp \left( \sum_{r>0} \frac{K_r}{r} H_{r} z^{\mp r} \right).$$

The relations have form

$$g(z, w) E(z) E(w) + g(w, z) E(w) E(z) = 0, \quad g(w, z) F(z) F(w) + g(z, w) F(w) F(z) = 0,$$

$$K^\pm(z) K^\pm(w) = K^\pm(w) K^\pm(z), \quad \frac{g(C^{-1} z, w)}{g(z, w)} K^-(z) K^+(w) = \frac{g(w, C^{-1} z)}{g(w, C z)} K^+(w) K^-(z),$$

$$g(z, w) K^\pm(C^{-1} z/2) E(w) + g(w, z) E(w) K^\pm(C^{-1} z/2) = 0,$$

$$g(w, z) K^\pm(C^{-1} z/2) F(w) + g(z, w) F(w) K^\pm(C^{-1} z/2) = 0,$$

$$[E(z), F(w)] = \frac{1}{\kappa_1} (\delta(C w/z) K^+(w) - \delta(z w/C) K^-(z)),$$

$$\text{Sym}_{z_1 z_2 z_3} z_1^{-1} [E(z_1), [E(z_2), E(z_3)]] = 0, \quad \text{Sym}_{z_1 z_2 z_3} z_2^{-1} [F(z_1), [F(z_2), F(z_3)]] = 0.$$

There exists an action of the group $\tilde{SL}(2, \mathbb{Z})$ on the toroidal algebra $U_q(\tilde{\mathfrak{gl}}_1)$ by automorphisms, see [7, Sec. 6.5]. We denote by $E_m^\perp, F_m^\perp, H_r^\perp$ images of generators $E_m, F_m, H_r$ after rotation of the lattice clockwise by 90 degrees. Under this rotation $C$ goes to $C^\perp$.

Denote by $d$ the operator

$$[d, E_m] = -m E_m, \quad [d, F_m] = -m F_m, \quad [d, H_r] = -r H_r, \quad [d, C] = [d, C^\perp] = 0.$$

This operator introduces the grading on the algebra $U_q(\tilde{\mathfrak{gl}}_1)$. Sometimes it is convenient to consider $d$ as an additional generator of $U_q(\tilde{\mathfrak{gl}}_1)$. Let $V$ be a representation of $U_q(\tilde{\mathfrak{gl}}_1)$ such that one can define an action of $d$ on the space $V$ with finite dimensional eigenspaces. By the character $\chi(V)$ denote the trace of operator $D = q^d$ where $q$ is a formal variable.

The algebra $U_q(\tilde{\mathfrak{gl}}_1)$ has the following formal coproduct

$$\Delta(H_r) = H_r \otimes 1 + C^{-r} \otimes H_r, \quad \Delta(H_{-r}) = H_{-r} \otimes C^r + 1 \otimes H_{-r}, \quad r > 0$$

$$\Delta(E(z)) = E \left( C_2^{-1} z \right) \otimes K^+ \left( C_2^{-1} z \right) + 1 \otimes E (z),$$

$$\Delta(F(z)) = F (z) \otimes 1 + K^- \left( C_1^{-1} z \right) \otimes F(C_1^{-1} z),$$

$$\Delta(X) = X \otimes X, \quad \text{for } X = C, C^\perp, D,$$

where $C_1 = C \otimes 1, C_2 = 1 \otimes C$.

In all representations of $U_q(\tilde{\mathfrak{gl}}_1)$ considered in this paper we have $C^\perp = 1$.

In the paper [13] authors defined the MacMahon modules of the algebra $U_q(\tilde{\mathfrak{gl}}_1)$. The MacMahon modules depend on three partitions $\mu, \nu, \lambda$ and two parameters $v, c \in \mathbb{C}$ (the central element $C$ acts of these modules as $c \text{Id}$). These modules are denoted by $\mathcal{M}_{\mu, \nu, \lambda}(v, c)$. This module has the basis $|a\rangle$, where $a$ is a plane partition which satisfies condition (1.2). The action of $d$ on $\mathcal{M}_{\mu, \nu, \lambda}(v, c)$ is defined by $d|a\rangle = |a| |a\rangle$. Therefore the

\footnote{Note that our $E_m, F_m, H_r$ are called $e_m^\perp, f_m^\perp, h_r^\perp$ in [13] (up to rescaling of $h_r$).}
character $\chi(M_{\mu,\nu,\lambda}(v,c))$ is equal to the generating function of plane partitions satisfying \((1.2)\).

The modules $M_{\mu,\nu,\lambda}(v,c)$ were originally defined by the explicit formulas for the action of “rotated” generators $E^+_m$, $F^+_m$, $H^+_m$ in the basis labeled by plane partitions. For example, the action of $K^{\perp,\pm}(z)$ have the form

$$K^{\perp,\pm}(z)|a\rangle = \frac{1 - e^2 v/z}{1 - v/z} \prod_{(i,j,k) \in a} \psi_{i,j,k}(v/z)|a\rangle \quad (5.2)$$

where

$$\psi_{i,j,k}(v/z) = \frac{(1 - q_i^{j-1}q_j^{k+1}v/z)(1 - q_i^{-k+1}q_j^{k}v/z)(1 - q_i^{k}q_j^{-k}v/z)}{(1 - q_i^j q_j^k v/z)(1 - q_i^{-j+1}q_j^{-k}v/z)(1 - q_i^{-j+1}q_j^{k}v/z)}.$$

Notation $(i, j, k) \in a$ means that $(i, j, k)$ belongs to the corresponding 3d Young diagram, see Fig. 1. It is easy to see that the product in the right side of \((5.2)\) becomes finite after cancellation of common factors. The highest weight of $M_{\mu,\nu,\lambda}(v,c)$ is given by the formula \((5.2)\) applied for “minimal” plane partition $a$ satisfying conditions \((1.2)\).

For generic values $c, v, q_1, q_2, q_3$ the module $M_{\mu,\nu,\lambda}(v,c)$ is irreducible. But for $c = q_1^{n/2} q_2^{m/2}$ (and generic $v, q_1, q_2, q_3$) this module has one singular vector. The quotient by the submodule generated by this vector is irreducible. This quotient is denoted by $N_{\mu,\nu,\lambda}^{n,m}(v)$ and has the basis $|a\rangle$ where $a$ is a plane partition, satisfying both conditions \((1.2)\) and \((1.1)\).

Recall that partitions $\lambda, \mu, \nu$ satisfy $l(\nu) \leq n$, $l(\mu) \leq m$, and $\lambda_{n+1} < m + 1$.

Therefore the character $\chi(N_{\mu,\nu,\lambda}^{n,m}(v))$ is equal to the generating function $\chi_{\mu,\nu,\lambda}^{n,m}(q)$ defined in the introduction. This is the representation theoretic interpretation of the left side of \((2.3), (2.4), (2.6)\). Now we will discuss the representation theoretic interpretation of the right sides.

### 5.2. It is difficult to write down the explicit action of the generators $E_m$, $F_m$, $H_m$ in the modules $N_{\mu,\nu,\lambda}^{n,m}(v)$. Now we recall a construction of another class of modules, namely, the Fock modules and intertwining operators between them, which are called screening operators. Then we sketch a construction of MacMahon modules $N_{\mu,\nu,\lambda}^{n,m}(v)$ in these terms.

The name of Fock modules over $U_q(\hat{gl}_1)$ comes from the fact that the representation space is identified with the Fock module over some Heisenberg algebra. In these representations the currents $E(z), F(z), K^\pm(z)$ are given in terms of the Heisenberg algebra (as combination of vertex operators).

We start from the basic Fock modules $F_u^{(i)}$, where $u = e^p$, $p \in \mathbb{C}$ and $i = 1, 2, 3$. These representations space is a module over a Heisenberg algebra with generators $a_n$, $n \in \mathbb{Z}$ and relations

$$[a_r, a_s] = r \frac{(q_i^{r/2} - q_i^{-r/2})^3}{-\kappa_r} \delta_{r+s,0}. \quad (5.3)$$

The space $F_u^{(i)}$ is generated by the highest weight vector $v_u^{(i)}$ such that

$$a_r v_u^{(i)} = 0 \quad \text{for } r > 0; \quad a_0 v_u^{(i)} = -\frac{\epsilon_i^2 p}{\epsilon_1 \epsilon_2 \epsilon_3} v_u^{(i)}.$$
Now we define representation \( \rho^{(i)}_u \) of \( U_q(\mathfrak{g}_1) \) in the space \( \mathcal{F}^{(i)}_u \) by the formulae

\[
\rho^{(i)}_u(E(z)) = \frac{u(1-q_i)}{\kappa_1} \exp \left( \sum_{r=1}^{\infty} \frac{q_i^{-r/2} \kappa_r}{r(q_i^{r/2} - q_i^{-r/2})^2} a_{-r}z^r \right) \exp \left( \sum_{r=1}^{\infty} \frac{\kappa_r}{r(q_i^{r/2} - q_i^{-r/2})^2} a_{-r}z^r \right),
\]

\[
\rho^{(i)}_u(F(z)) = \frac{u^{-1}(1-q_i^{-1})}{\kappa_1} \exp \left( \sum_{r=1}^{\infty} \frac{-\kappa_r}{r(q_i^{r/2} - q_i^{-r/2})^2} a_{-r}z^r \right) \exp \left( \sum_{r=1}^{\infty} \frac{-q_i^{r/2} \kappa_r}{r(q_i^{r/2} - q_i^{-r/2})^2} a_{-r}z^r \right),
\]

\[
\rho^{(i)}_u(H_r) = \frac{a_r}{q_i^{r/2} - q_i^{-r/2}}, \quad \rho^{(i)}_u(C^\perp) = 1, \quad \rho^{(i)}_u(C) = q_i^{1/2},
\]

\[
\rho^{(i)}_u(d)v^{(i)}_u = \Delta_i(p)v^{(i)}_u, \quad \text{where } \Delta_i(p) = \frac{(p + \epsilon_i)^3 - p^3}{6\epsilon_1\epsilon_2\epsilon_3}.
\]

Note that generally speaking the operators \( a_0 \) and \( d \) can act on the highest weight vector \( v^{(i)}_u \) by any numbers. Our choice is convenient for the formulas below, for example, the screening operators will commute with \( d \) due to our choice.

We formally introduce operators \( \hat{Q} \) by the relation \([a_n, \hat{Q}] = -\frac{\epsilon_i^3}{\epsilon_1\epsilon_2\epsilon_3} \delta_{n,0}\). This operator does not act on our representation spaces but for \( x \in \mathbb{C} \) we define operator

\[ e^{x\hat{Q}} : \mathcal{F}^{(i)}_u \to \mathcal{F}^{(i)}_{q^u x} \text{ such that } \]

\[ [a_n, e^{x\hat{Q}}] = 0, \text{ for } n \neq 0, \quad e^{x\hat{Q}}v^{(i)}_u = v^{(i)}_{q^u x}.
\]

The \( U_q(\mathfrak{g}_1) \) modules \( \mathcal{F}^{(i)}_u \) are irreducible. In terms of the rotated generators, their highest weight has the form

\[
K^{1,\pm}(z)v^{(i)}_u = \frac{1 - q_iu/z}{1 - u/z}v^{(i)}_u.
\]

In particular, the highest weight of the Fock module \( \mathcal{F}^{(1)}_u \) coincides with the highest weight of the Macmahon module \( \mathcal{M}_{\varnothing,(v_1),(\lambda_1)}(v,c) \) for \( c = q_1^{1/2} \) and \( u = vq_1^{\lambda_1}q_3^{\mu_1} \) (see (5.2)). Therefore the irreducible quotient \( \mathcal{N}^{1,0}_{\varnothing,(v_1),(\lambda_1)}(v) \) is isomorphic to the Fock module \( \mathcal{F}^{(2)}_u \). Similarly the MacMahon module \( \mathcal{N}^{0,1}_{(\mu_1),\varnothing,(\lambda_1)}(v) \) is isomorphic to the Fock module \( \mathcal{F}^{(3)}_u \), where \( u = vq_1^{\lambda_1}q_3^{\mu_1} \).

The highest weight of the module \( \mathcal{N}^{n,m}_{\mu,\nu,\lambda}(v) \) is given by the rational function which can be decomposed as the product of several factors of the type \( [5,5] \). Therefore \( \mathcal{N}^{n,m}_{\mu,\nu,\lambda}(v) \) is isomorphic to a subquotient of a tensor product of a Fock modules

\[ \mathcal{F}^{(i_1)}_{u_1} \otimes \mathcal{F}^{(i_2)}_{u_2} \otimes \cdots \otimes \mathcal{F}^{(i_k)}_{u_k}. \]

Clearly such tensor product is also a Fock representation of the sum of \( k \) copies of the Heisenberg algebras or, in other words, Heisenberg algebra with generators \( a_{r,i}, r \in \mathbb{Z}, 1 \leq i \leq k \). Now we will describe the image of \( U_q(\mathfrak{g}_1) \) in these representations.

**5.3.** First, we consider the tensor product \( \mathcal{F}^{(i_1)}_{u_1} \otimes \mathcal{F}^{(i_2)}_{u_2} \). This tensor product was essentially elaborated in [17] which we follow. We introduce the Heisenberg generators \( h_n \) acting on \( \mathcal{F}^{(i_1)}_{u_1} \otimes \mathcal{F}^{(i_2)}_{u_2} \)

\[
h_{-r} = q_i^{r/2}(a_{-r} \otimes 1) - q_i^{-r/2}(1 \otimes a_{-r}), \quad h_r = q_i^{-r/2}(a_r \otimes 1) - q_i^{r/2}(1 \otimes a_r), \quad r > 0.
\]
For any $n \in \mathbb{Z} \setminus \{0\}$ we have satisfy $[h_n, \Delta(H_m)] = 0$ for all $m \in \mathbb{Z} \setminus \{0\}$ and, clearly, $h_n$ is unique (up to normalization) linear combination of $a_n \otimes 1$ and $1 \otimes a_n$ with such property. In our normalization we have

$$[h_r,h_s] = \frac{r(q_i^r - q_i^{-r})(q_i^{r/2} - q_i^{-r/2})^2}{-\kappa_r} \delta_{r+s,0}. $$

Denote $\hat{Q}_1 = \hat{Q} \otimes 1$, $\hat{Q}_2 = 1 \otimes \hat{Q}$, $u_1 = e^{p_1}$, $u_2 = e^{p_2}$. Following [12] we introduce two screening operators

$$S^i_+ (z) = e^{\frac{i+1}{r_1}(\hat{Q}_1 - \hat{Q}_2)z} e^{p_{\frac{r_1}{r_1+1}i}} \exp \left( \sum_{r=1}^{\infty} \frac{-(q_i^{r/2} - q_i^{-r/2})}{r(q_i^{r/2} - q_i^{-r/2})} h_{-r} z^r \right) \exp \left( \sum_{r=1}^{\infty} \frac{(q_i^{r/2} - q_i^{-r/2})}{r(q_i^{r/2} - q_i^{-r/2})} h_{r} z^{-r} \right) \tag{5.7}$$

$$S^i_- (z) = e^{\frac{i-1}{r_1}(\hat{Q}_1 - \hat{Q}_2)z} e^{p_{\frac{r_1}{r_1+1}i}} \exp \left( \sum_{r=1}^{\infty} \frac{-(q_i^{-r/2} - q_i^{r/2})}{r(q_i^{-r/2} - q_i^{r/2})} h_{-r} z^r \right) \exp \left( \sum_{r=1}^{\infty} \frac{(q_i^{-r/2} - q_i^{r/2})}{r(q_i^{-r/2} - q_i^{r/2})} h_{r} z^{-r} \right).$$

**Lemma 5.1.** The following screening operators

$$S^i_+ = \oint S^i_+(z) dz, \quad S^i_- = \oint S^i_-(z) dz. \tag{5.8}$$

commutes with action of $U_q(\mathfrak{gl}_1)$ (including the operator $d$).

Here $\oint$ is an integral over small contour around 0 (residue at 0). This integral is defined if the corresponding power of $z$ is integer. In other words the operator $S^i_\pm$ acts on the tensor product $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$ if and only if $p_{\frac{r_1}{r_1+1}i} \in \mathbb{Z}$ and similarly for $S^i_-$. The lemma follows from a direct computation, which shows that commutator $[E(z), S^i_\pm] = D_{q^{\pm 1}}(G)$ where $[D_{n}f](w) = \frac{f^{(n)}(w) - f(wo)}{w}$ and $G$ is some current.

Note that the screening currents formally commute

$$S^i_+(z)S^i_-(w) = \frac{1}{(z - q_i^{-1/2} w)(z - q_i^{-1/2} w)} :S^i_+(z)S^i_-(w): = S^i_-(w)S^i_+(z).$$

We denote by $W_q(\mathfrak{gl}_2)$ the quotient of $U_q(\mathfrak{gl}_1)$ by the two-sided ideal generated by operators, which act as 0 on any tensor product $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$. It was proven in [17, Sec. 2.4] that this definition is equivalent to the standard definition of $q$-deformed $W$-algebra. This $W$-algebra is just the product of Heisenberg algebra and deformed Virasoro algebra introduced in [38]. We will use results on the representation theory of the latter.

For generic $u_1, u_2$ the module $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$ is irreducible. But if $u_2 = u_1 q_s q_{t-1}^s$ where $s, t \in \mathbb{Z}$ and $st > 0$ then it is not so. If $s, t < 0$, then $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$ has singular vector and this singular vector can be obtained by the action of the power of screening operator [38, Sec. 5]. The quotient of $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$ by the submodule generated by this singular vector is irreducible. The highest weight of this irreducible quotient coincides with the highest weight of $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$ and actually coincides with the highest weight of $\mathcal{N}^{2,0}_{\{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v)$.

Since the MacMahon module $\mathcal{N}^{2,0}_{\{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v)$ is also irreducible we proved that it is isomorphic to the quotient of $\mathcal{F}^{(i)}_{u_1} \otimes \mathcal{F}^{(i)}_{u_2}$. This can be written as a short exact sequence.
The simplest example of such complex given if \( s \) or \( t \) equal to 1

\[
0 \to \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \otimes \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \xrightarrow{S_{11}} \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \otimes \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \to \mathcal{N}^{2,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v) \to 0.
\]

For a generic module \( \mathcal{N}^{2,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v) \) the corresponding short exact sequences have the form

\[
0 \to \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \otimes \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \xrightarrow{(S_{11})_{v_1^{-1} v_2^{-1} + 1}} \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \otimes \mathcal{F}^{(1)}_{vq_2^{-1} q_3^{-1}} \to \mathcal{N}^{2,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v) \to 0
\]

(5.9)

where operators \((S_{11})^r\) should be considered as \( r \)-fold integrals over the appropriate cycle with the appropriate additional (Lukyanov) factor (see [25]). Now we compute the Euler characteristic of (5.9). Using \( \chi(\mathcal{F}^{(1)}_{u_1} \otimes \mathcal{F}^{(1)}_{u_2}) = q^{\Delta_1(p_1) + \Delta_1(p_2)} / (q^2)^{\infty} \), where \( \Delta_i(p) \) is defined in (5.4) we have

\[
\chi(\mathcal{N}^{2,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v)) = q^\Delta q^{-(\lambda_1 + 1)\nu_1 + \lambda_2 \nu_2} - q^{-(\lambda_1 + 1)\nu_1 - \lambda_2 (\nu_2 + 1)} \frac{(q^2)^{\infty}}{(q^2)^{\infty}},
\]

(5.10)

where

\[
\Delta = \Delta_1(p + \nu_1 \epsilon_2 + \lambda_1 \epsilon_3) + \Delta_1(p + (\nu_2 - 1) \epsilon_2 + (\lambda_2 - 1) \epsilon_3) + (\lambda_1 + 1)\nu_1 + \lambda_2 \nu_2,
\]

and \( e^p = v \). Up to the factor \( q^\Delta \) the formula (5.10) coincides with (2.6) (or with its special case (1.4)).

In a similar manner one can construct resolutions of \( \mathcal{N}^{n,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v) \) in terms of \( \mathcal{F}^{(1)}_{u_1} \otimes \mathcal{F}^{(2)}_{u_2} \).

Below we will discuss the algebra of screening operators which commute with the image of algebra \( U_q(\hat{\mathfrak{gl}}_1) \) in the representation \( \mathcal{F}^{(1)}_{u_1} \otimes \ldots \otimes \mathcal{F}^{(1)}_{u_n} \). This system of screening operators coincides with the one studied in [12], the algebra which commutes with them (i.e., image of \( U_q(\hat{\mathfrak{gl}}_1) \)) is \( W_q(\hat{\mathfrak{gl}}_n) \). We conjecture that one can construct resolutions of \( \mathcal{N}^{n,0}_{\emptyset, \{\nu_1, \nu_2\}, \{\lambda_1, \lambda_2\}}(v) \) in terms of the modules \( \mathcal{F}^{(1)}_{u_1} \otimes \ldots \otimes \mathcal{F}^{(n)}_{u_n} \). See Section 5.5 for more details.

### 5.4. Second, we consider the tensor product \( \mathcal{F}^{(1)}_{u_1} \otimes \mathcal{F}^{(2)}_{u_2} \). We introduce the Heisenberg generators \( h_n \) acting on \( \mathcal{F}^{(1)}_{u_1} \otimes \mathcal{F}^{(2)}_{u_2} \)

\[
h_{-r} = \frac{q_1^{-r} (q_1^{r/2} - q_2^{-r/2})}{q_1^{r/2} - q_2^{-r/2}} (a_{-r} \otimes 1) - \frac{q_1^{-r} (q_1^{r/2} - q_2^{-r/2})}{q_1^{r/2} - q_2^{-r/2}} (1 \otimes a_{-r}),
\]

\[
h_r = \frac{q_1^{r} (q_1^{r/2} - q_2^{-r/2})}{q_1^{r/2} - q_2^{-r/2}} (a_{r} \otimes 1) - \frac{q_1^{-r} (q_1^{r/2} - q_2^{-r/2})}{q_1^{r/2} - q_2^{-r/2}} (1 \otimes a_{r}),
\]

(5.11)

ny \( n \in \mathbb{Z} \setminus \{0\} \) we have satisfy \( [h_n, \Delta(H_m)] = 0 \) for all \( m \in \mathbb{Z} \setminus \{0\} \) and, clearly, \( h_n \) is unique (up to normalization) linear combination of \( a_n \otimes 1 \) and \( 1 \otimes a_n \) with such property. In our normalization we have

\[
[h_r, h_s] = r \delta_{r+s,0}.
\]
Similarly to the previous case, denote 
\( \hat{Q}_1 = \hat{Q} \otimes 1, \hat{Q}_2 = 1 \otimes \hat{Q} \), 
and introduce a screening current
\[
S^{12}(z) = e_{\nu_1}^{\frac{\nu_2}{\nu_3}} \hat{Q}_1 - e_{\nu_2}^{\frac{\nu_2}{\nu_3}} \hat{Q}_2 \z \exp \left( \sum_{r=1}^{\infty} \frac{1}{r} h_{-r} z^{-r} \right) \exp \left( \sum_{r=1}^{\infty} \frac{1}{r} h_{r} z^{-r} \right).
\] (5.12)

**Lemma 5.2.** The following screening operator
\[
S^{12} = \oint S^{12}(z) dz.
\] (5.13)
commutes with action of \( U_q(\hat{\mathfrak{gl}}_1) \) (including the operator \( d \)).

This lemma follows from a direct computation (see also comments after the Lemma 5.1).

Note that in this case we have only one screening current contrary to two currents \( S^{11}_{\nu_1}(z), S^{12}_{\nu_2}(z) \) above in (5.11). Also note that the commutation relations of \( S^{12}(z) \) do not depend on \( q_1, q_2, q_3 \).

We denote by \( W_q(\hat{\mathfrak{gl}}_{11}) \) the quotient of \( U_q(\hat{\mathfrak{gl}}_1) \) by the two-sided ideal generated by operators, which act as 0 on any tensor product \( \mathcal{F}_{u_1}^{(1)} \otimes \mathcal{F}_{u_2}^{(2)} \). The arguments for such name will be given below.

For generic \( u_1, u_2 \) the module \( \mathcal{F}_{u_1}^{(1)} \otimes \mathcal{F}_{u_2}^{(2)} \) is irreducible. But in the resonance case we have nontrivial intertwining operators between such modules and can construct a complex with cohomology \( \mathcal{N}^{1,1}_{\{\mu_1\},\{\nu_1\},\varpi}(v) \).

There are two infinite exact sequences (Of course, the exactness is nontrivial, here we omit the proof)
\[
\ldots \xrightarrow{S^{12}} \mathcal{F}_{v_{q_2} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_7} g_3}^{(2)} \xrightarrow{S^{12}} \mathcal{F}_{v_{q_2} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_7} g_3}^{(2)} \xrightarrow{S^{12}} \mathcal{F}_{v_{q_7} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_2} g_3}^{(2)} \rightarrow \mathcal{N}^{1,1}_{\{\mu_1\},\{\nu_1\},\varpi}(v) \rightarrow 0,
\] (5.14)
\[
0 \rightarrow \mathcal{N}^{1,1}_{\{\mu_1\},\{\nu_1\},\varpi}(v) \xrightarrow{S^{12}} \mathcal{F}_{v_{q_2} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_7} g_3}^{(2)} \xrightarrow{S^{12}} \mathcal{F}_{v_{q_2} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_7} g_3}^{(2)} \xrightarrow{S^{12}} \mathcal{F}_{v_{q_7} g_3}^{(1)} \otimes \mathcal{F}_{v_{q_2} g_3}^{(2)} \xrightarrow{S^{12}} \ldots
\] (5.15)

Now we calculate the Euler characteristics of exact sequences (5.14) and (5.15). Introduce \( p \) by \( e^p = v \) and \( \Delta = \Delta_1(p + \nu_1 \epsilon_3) + \Delta_2(p + \epsilon_1 + \mu_1 \epsilon_3) \). We have an algebraic identity (using the definition (5.4))
\[
\Delta_1(p + \nu_1 \epsilon_3 - a \epsilon_2) + \Delta_2(p + (a + 1) \epsilon_1 + \mu_1 \epsilon_3) - \Delta = \left( \frac{a + 1}{2} \right) + (\nu_1 - \mu_1)a.
\]

Therefore
\[
\chi\left( \mathcal{N}^{1,1}_{\{\mu_1\},\{\nu_1\},\varpi}(v) \right) = q^\Delta R(\nu_1 - \mu_1; q)
\] (5.16)
where function $R$ is defined in (2.2). Up to a factor $q^{-}$ this formula coincides with (2.6) for this special case $n = m = 1$.

5.5. Now we want to consider tensor products

$$F_{u_1}^{(1)} \otimes \cdots \otimes F_{u_n}^{(1)} \otimes F_{u_{n+1}}^{(2)} \otimes \cdots \otimes F_{u_{n+m}}^{(2)},$$

(5.17)

Similarly to previous discussion we expect that the MacMahon module $N^{n,m}_{\mu,\nu,\lambda}(v)$ admits a resolution consisting of modules of the type (5.17). For example one can easily see that the central charge of $N^{n,m}_{\mu,\nu,\lambda}(v)$ and central charge of (5.17) are both equal to $c = q_1^{n/2} q_2^{m/2}$.

Moreover we can consider another ordering in the tensor product (5.17). For generic parameters $u$ any tensor product of $n$ modules $F_{u_i}^{(1)}$ and $m$ modules $F_{u_j}^{(2)}$ is isomorphic to the product in the ordering (5.17). For each pair of neighbor Fock modules $F_{u_i}^{(i)} \otimes F_{u_{i+1}}^{(i+1)}$ we constructed above the screening operators $(S_{i,i+1}^{*})_{l,l+1}$, where indices $l, l+1$ label Fock modules in which this operator act and $* = \pm$ if $i_l = i_{l+1}$, while $*$ should be ignored when $i_l = i_{l+1}$. For any $l, *$ the operator $(S_{i,i+1}^{*})_{l,l+1}$ commutes with $U_{\tilde{q}}(\mathfrak{gl}_1)$.

For modules (5.17) it is convenient to decompose the corresponding screening operators into 3 systems:

$$\mathcal{G}_1 = \left\{ (S_{11}^{i})_{i,i+1} | 0 < i < n \right\},$$

$$\mathcal{G}_2 = \left\{ (S_{22}^{j})_{j,j+1} | n < j < n + m \right\},$$

$$\mathcal{G}_3 = \left\{ (S_{11}^{i})_{i,i+1}, (S_{12}^{n,n+1}), (S_{22}^{j})_{j,j+1} | 0 < i < n, n < j < n + m \right\}.$$

(5.18)

We will denote by $W_{\tilde{q}}(\mathfrak{gl}_{n|m})$ the quotient of $U_{\tilde{q}}(\mathfrak{gl}_1)$ by the two-sided ideal generated by operators, which act as 0 on any tensor product (5.17).

Now we discuss a representation theoretic interpretation of the character formulas (2.6), (2.14), (2.15).

• Each term in the sum of right side of (2.6) has the form of $q^{\Lambda}/(q^{n+m})$. This is the character of the Fock module (5.17). Therefore it is natural to expect that right side of (2.6) is an Euler characteristic of a resolution, consisting of Fock modules (5.17). The terms in this resolution should be labeled by $(\sigma, \tau, A) \in \Theta$ as in (2.6). We will say that this resolution is a materialization of the formula (2.6).

This resolution of $W_{\tilde{q}}(\mathfrak{gl}_{n|m})$ modules is a generalization of resolutions (5.9) and (5.14), (5.15) discussed above. The intertwining operators in this resolution could be constructed using screening operators. The construction of such resolution is unknown (actually we did not give a proof of the existence of (5.9) and (5.14), (5.15) but these particular cases are rather easy).

Even in the case $m = 0$ which corresponds to $W_{\tilde{q}}(\mathfrak{gl}_n)$ we did not find this resolution in the literature. It is well known that conformal limit of such resolution exists. For the construction of intertwining operators in the $W_{\tilde{q}}(\mathfrak{gl}_n)$ case see [16].

• The algebra $U_{\tilde{q}}(\mathfrak{gl}_1)$ acts on the product of first $n$ factors of (5.17) through the quotient $W_{\tilde{q}}(\mathfrak{gl}_n)$ and acts on the product of last $m$ factors of (5.17) through the quotient $W_{\tilde{q}}(\mathfrak{gl}_m)$. Therefore algebra $W_{\tilde{q}}(\mathfrak{gl}_{n|m})$ is a subalgebra of $W_{\tilde{q}}(\mathfrak{gl}_n) \otimes W_{\tilde{q}}(\mathfrak{gl}_m)$. The latter algebra
has representations of the form $\mathcal{N}_{\varnothing,\nu,\bar{\rho}}^{n,0}(v_1) \otimes \mathcal{N}_{\mu,\varnothing,\bar{\mu}}^{0,m}(v_2)$. Since the character of each factor is given by formula (1.4) we have
\[
\chi(\mathcal{N}_{\varnothing,\nu,\bar{\rho}}^{n,0}(v_1) \otimes \mathcal{N}_{\mu,\varnothing,\bar{\mu}}^{0,m}(v_2)) = q^\Delta a_{\nu+\rho}(q^{\bar{\rho} - \rho}) a_{\mu+\rho}(q^{\bar{\mu} - \rho}),
\]
for certain $\Delta$. The right side of the character formula (2.4) is a linear combination of such terms. Therefore it is natural to expect that there exists a resolution of $\mathcal{N}_{\mu,\nu,\lambda}(v)$ consisting of modules $\mathcal{N}_{\varnothing,\nu,\bar{\rho}}^{n,0}(v_1) \otimes \mathcal{N}_{\mu,\varnothing,\bar{\mu}}^{0,m}(v_2)$ with the cohomology $\mathcal{N}_{\mu,\nu,\lambda}^{n,m}(v)$. This resolutions should be a materialization of the character formula (2.4). See also Section 5.7 below.

- Consider tensor product
\[
\mathcal{F}_{u_1}^{(1)} \otimes \ldots \otimes \mathcal{F}_{u_{n-r}}^{(1)} \otimes \mathcal{F}_{u_{n-r+1}}^{(2)} \otimes \ldots \otimes \mathcal{F}_{u_{n+m-2r}}^{(2)} \otimes \mathcal{F}_{u_{n+m-2r+1}}^{(1)} \otimes \ldots \otimes \mathcal{F}_{u_{n+m-1}}^{(1)} \otimes \mathcal{F}_{u_{n+m}}^{(2)},
\]
As mentioned before this product is isomorphic to (5.17).

The algebra $U_{\bar{q}}(\mathfrak{gl}_1)$ acts on the product through the algebra $W_{\bar{q}}(\mathfrak{gl}_1)^{\otimes (n+m-2r)} \otimes W_{\bar{q}}(\mathfrak{gl}_1^1)^{\otimes r}$, where $W_{\bar{q}}(\mathfrak{gl}_1)^{\otimes n+m-2r}$ is by definition just Heisenberg algebra acting on the first $n+m-2r$ factors of (5.3). Therefore $W_{\bar{q}}(\mathfrak{gl}_1^m)$ is a subalgebra of $W_{\bar{q}}(\mathfrak{gl}_1)^{\otimes n+m-2r} \otimes W_{\bar{q}}(\mathfrak{gl}_1^1)^{\otimes r}$. The latter $W$-algebra has representations
\[
\mathcal{F}_{u_1}^{(1)} \otimes \ldots \otimes \mathcal{F}_{u_{n-r}}^{(1)} \otimes \mathcal{F}_{u_{n-r+1}}^{(2)} \otimes \ldots \otimes \mathcal{F}_{u_{n+m-2r}}^{(2)} \otimes \mathcal{N}_{r,1}^{(1)}(\mathfrak{gl}_1^1) \otimes \ldots \otimes \mathcal{N}_{r,1}^{(1)}(\mathfrak{gl}_1^m) \otimes \ldots \mathcal{N}_{r,1}^{(1)}(\mathfrak{gl}_1^l) \otimes \mathcal{F}_{u_r}^{(2)}.
\]
Due to (5.13) the character of this representations equals $\prod_{i=1}^r R(d_i; q) \cdot q^\Delta / (q^\infty)^{m+n-2r}$, where $d_i = n_i - m_i$ and $\Delta$ is specified by parameters $u_i, v_i, l_i, n_i$.

If we compute the determinant in right side of (2.3) we get the linear combination of terms $\prod_{i=1}^r R(d_i; q) \cdot q^\Delta / (q^\infty)^{m+n-2r}$ as before. Therefore it is natural to conjecture the existence of the resolution of $\mathcal{N}_{\mu,\nu,\lambda}^{n,m}(v)$ consisting of modules of the type (5.20). And this resolution should be a materialization of the character formula (2.3).

5.6. Now we consider conformal limit of the previous construction. We rescale $\epsilon_i \to h \epsilon_i, p_i \to h p_i$ and then send $h$ to zero, i.e., send all parameters $q_i, u_i$ to 1 with a certain speed. Now consider the limit of screening operators, we will see that this limit is well defined.

Let $C^{n+m}$ be a vector space with the scalar product $(\cdot, \cdot)$ given in orthogonal basis $e_i$ by the formula
\[
(e_i, e_i) = -\frac{\epsilon_i^2}{2\epsilon_3}, \quad (e_j, e_j) = -\frac{\epsilon_j^2}{2\epsilon_3}, \quad 1 \leq i \leq n, n+1 \leq j \leq n+m.
\]

Denote by $\bar{a}_{n,l}$, $n \neq 0$ the limit of generators $a_n$ acting on the $l$-th factor in (5.17). As the limit of (5.3) we get
\[
[\bar{a}_{r,i}, \bar{a}_{s,i}] = -r(e_i, e_j) \delta_{n,0r+s,0}.
\]
By $\bar{Q}_l$ we denote a limit of $\bar{Q}_l$, and by $\bar{a}_{0,l}$ we denote
\[
\bar{a}_{0,i} = \lim_{h \to 0} a_{0,i} - i\frac{\epsilon_i^2}{2\epsilon_3}, \quad \bar{a}_{0,i} = \lim_{h \to 0} a_{0,i} - n\frac{\epsilon_i^2}{2\epsilon_3} - (j-n)\frac{\epsilon_j^2}{2\epsilon_3}, \quad 1 \leq i \leq n, n+1 \leq j \leq n+m,
\]
here such strange shifts are introduced in order to hide factors like $\epsilon^2/\epsilon_3$ in the definition of $S^{12}$ in (5.12). Anyway, we get a relation $[\bar{a}_{0,l}, \bar{Q}_l] = (e_l, e_l)$. 

It is convenient to introduce

\[ \varphi_l(z) = \sum_{r \in \mathbb{Z} \setminus 0} \tilde{a}_{n,l} z^{-r} + \tilde{a}_{0,l} \log z + \tilde{Q}_l, \]  

(5.21)

Then, the limit of screening currents has the form

\[
\begin{align*}
\lim_{\hbar \to 0} (S^{11}_\pm (z))_{i,i+1} &= \exp \left( \sum_{l=1}^{n+m} (\alpha_{\pm,i,l} \varphi_l(z)) \right), \quad 0 < i < n, \\
\lim_{\hbar \to 0} (S^{12}_\pm (z))_{n,n+1} &= \exp \left( \sum_{l=1}^{n+m} (\alpha_n \varphi_l(z)) \right), \\
\lim_{\hbar \to 0} (S^{22}_\pm (z))_{j,j+1} &= \exp \left( \sum_{l=1}^{n+m} (\alpha_{\pm,j,l} \varphi_l(z)) \right), \quad n < j < n + m.
\end{align*}
\]

Here \( \cdots \) is a standard Heisenberg normal ordering. We consider \( \alpha_{\pm,i}, \alpha_n, \alpha_{\pm,j} \) as the vectors in \( \mathbb{C}^{n+m} \) which have the form

\[
\begin{align*}
\alpha_{+,i} &= \frac{\epsilon_2}{\epsilon_1} \epsilon_i - \frac{\epsilon_2}{\epsilon_1} \epsilon_{i+1}, \\
\alpha_n &= \frac{\epsilon_2}{\epsilon_1} \epsilon_n - \frac{\epsilon_1}{\epsilon_2} \epsilon_{n+1}, \\
\alpha_{-,j} &= \frac{\epsilon_3}{\epsilon_1} \epsilon_j - \frac{\epsilon_3}{\epsilon_1} \epsilon_{j+1}, \\
\alpha_{+,j} &= \frac{\epsilon_3}{\epsilon_2} \epsilon_j - \frac{\epsilon_3}{\epsilon_2} \epsilon_{j+1}.
\end{align*}
\]

Slightly abusing notation we will say that \( \alpha \in \mathcal{S}_I \), for \( I = 1, 2, 3 \) if the corresponding screening operator belongs to \( \mathcal{S}_I \).

For any \( \beta, \gamma \in \mathbb{C}^{n+m} \) the commutation relations of vertex operators have the form

\[
\exp \left( \sum_{l=1}^{n+m} \beta_l \varphi_l(z) \right) \cdot \exp \left( \sum_{l=1}^{n+m} \gamma_l \varphi_l(w) \right) = (z - w)^{\beta,\gamma} \exp \left( \sum_{l=1}^{n+m} \beta_l \varphi_l(z) + \gamma_l \varphi_l(w) \right). 
\]

In particular, if \( (\beta, \gamma) \in 2\mathbb{Z} \) then the corresponding vertex operators formally commute and if \( (\beta, \gamma) \in 2\mathbb{Z} + 1 \) then the corresponding vertex operators formally anticommute. It is easy to see that if two vectors \( \alpha, \alpha' \) belong to different systems \( \mathcal{S} \) then the scalar product \( (\alpha, \alpha') \in \mathbb{Z} \), i.e., corresponding screening operators formally commute. The Gramian matrices for vectors from \( \mathcal{S}_1, \mathcal{S}_2, \mathcal{S}_3 \) are given below

\[
\mathcal{S}_1: \begin{pmatrix}
-\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} & 0 & \ldots & 0 \\
\frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} & \cdots & \vdots \\
0 & \ldots & \frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} \\
\vdots & \ddots & \ddots & \ddots & \ddots \\
0 & \ldots & 0 & \frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2}
\end{pmatrix}, \\
\mathcal{S}_2: \begin{pmatrix}
-\frac{2\epsilon_1}{\epsilon_1} & \frac{\epsilon_1}{\epsilon_1} & 0 & \ldots & 0 \\
\frac{\epsilon_1}{\epsilon_1} & -\frac{2\epsilon_1}{\epsilon_1} & \frac{\epsilon_1}{\epsilon_1} & \cdots & \vdots \\
0 & \ldots & \frac{\epsilon_1}{\epsilon_1} & -\frac{2\epsilon_1}{\epsilon_1} & \frac{\epsilon_1}{\epsilon_1} \\
\vdots & \ddots & \ddots & \ddots & \ddots \\
0 & \ldots & 0 & \frac{\epsilon_1}{\epsilon_1} & -\frac{2\epsilon_1}{\epsilon_1}
\end{pmatrix}, \\
\mathcal{S}_3: \begin{pmatrix}
-\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} & 0 & \ldots & 0 \\
\frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} & \cdots & \vdots \\
0 & \ldots & \frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2} & \frac{\epsilon_1}{\epsilon_2} \\
\vdots & \ddots & \ddots & \ddots & \ddots \\
0 & \ldots & 0 & \frac{\epsilon_1}{\epsilon_2} & -\frac{2\epsilon_1}{\epsilon_2}
\end{pmatrix},
\]
of braided tensor categories, but we do not need tensor structure here.

Kazhdan–Lusztig theorems [26]. In fact, this equivalence of categories is an equivalence of the abelian categories of certain representations of a vertex algebra and certain representations of a quantum group. This is a statement similar to the Drinfeld–Kohno or Kazhdan–Lusztig theorems [26].

The Gramian matrix corresponding to $\mathfrak{g}_1$ is equal to the Cartan matrix of $\mathfrak{sl}_n$ multiplied by $-\frac{\epsilon_1}{\epsilon_2}$. The $W$-algebra commuting with screening operators with such Gramian matrix is called $W(\mathfrak{g}_1)$ see [11], the parameter $-\frac{\epsilon_1}{\epsilon_2}$ is responsible for central charge. In our case the $W$-algebra is $W(\mathfrak{g}_1) \otimes \text{Heis} \otimes m$ since there exists $m + 1$ dimensional Heiseberg algebra which commutes with all screening operators from $\mathfrak{g}_1$. Similarly, commutativity with screening operators from $\mathfrak{g}_2$ determines $W$-algebra $\text{Heis} \otimes n \otimes W(\mathfrak{g}_m)$.

The Gramian matrix corresponding to $\mathfrak{g}_3$ have blocks corresponding to $\mathfrak{sl}_n, \mathfrak{sl}_m$ and fermionic screening operator between them. Therefore we call the $W$-algebra commuting with this system $W(\mathfrak{g}_m|n)$. The $W(\mathfrak{g}_m|n)$ case was considered in [21], but we did not find any reference for general $n, m$. Note that our $W$-algebras differ from the ones introduced in [27].

We expect that resolutions constructed in Section 5.5 has conformal limit. We discuss their quantum group meaning in the next section.

5.7. A standard statement (conjecture) in the theory of vertex algebras is an equivalence of the abelian categories of certain representations of a vertex algebra and certain representations of a quantum group. This is a statement similar to the Drinfeld–Kohno or Kazhdan–Lusztig theorems [26]. In fact, this equivalence of categories is an equivalence of braided tensor categories, but we do not need tensor structure here.

It is known that a certain category of representations of the vertex algebra $W(\mathfrak{g}_1)$ is equivalent to a certain category of representations of the quantum group $U_q \mathfrak{g}_1 \otimes U_q \mathfrak{g}_n$, where parameters $q, q'$ are given in terms of $\epsilon_1, \epsilon_2$ (people also use modular double of $U_q \mathfrak{g}_n$). We conjecture that the same relation holds for the vertex algebra $W(\mathfrak{g}_m|n)$ and the quantum group $U_q \mathfrak{g}_m \otimes U_q \mathfrak{g}_n \otimes U_q \mathfrak{g}_m$ for certain $q, q', q''$ given in terms of $\epsilon_1, \epsilon_2$.

Denote by $L^{(n)}_\nu$ the finite dimensional irreducible representation of $U_q(\mathfrak{g}_n)$, recall that these representations are labeled by partitions $\nu$ such that $l(\nu) \leq n$. Similarly denote by $L^{(m)}_\mu$ the finite dimensional irreducible representation of $U_q(\mathfrak{g}_m)$.

For $U_q \mathfrak{g}_{m|n}$ we will consider two types of representations. It is known (see [4], [37]) that irreducible submodules of the tensor powers of $\mathbb{C}^{n|m}$ are labeled by partitions $\lambda$ such that $\lambda_{n+1} < m + 1$, such irreducible modules are called tensor representation. We denote an analogous representation of $U_q \mathfrak{g}_{m|n}$ by $L^{(n|m)}_\lambda$. Let $p \subset \mathfrak{g}_{m|n}$ be a parabolic
subalgebra with a Levi subgroup $\mathfrak{gl}_s \oplus \mathfrak{gl}_m$. The algebra $\mathfrak{p}$ acts on a tensor product of finite dimensional representations of $\mathfrak{gl}_n$ and $\mathfrak{gl}_m$ and a corresponding induced $\mathfrak{gl}_{n|m}$ module is called Kac module. We denote an analogues representation for $U_q \mathfrak{gl}_{n|m}$ by $\tilde{V}_{\nu, \mu}$, where $\tilde{\nu}, \tilde{\mu}$ label the finite dimensional representations of $\mathfrak{gl}_n$ and $\mathfrak{gl}_m$ correspondingly.

We conjecture that under the aforementioned equivalence the tensor product of irreducible modules $L_\lambda^{(n|m)} \otimes L_\nu^{(n)} \otimes L_\mu^{(m)}$ goes to the conformal limit of $\mathcal{N}_{\mu, \nu, \lambda}^{n,m}(v)$, and tensor product $V_{\tilde{\nu}, \tilde{\mu}} \otimes L_\nu^{(n)} \otimes L_\mu^{(m)}$ goes to the conformal limit of $\mathcal{N}_{\tilde{\nu}, \nu, \tilde{\mu}}^{n,0}(v_1) \otimes \mathcal{N}_{\nu, \nu, \lambda}^{0,m}(v_2)$.

In paper [8] Cheng, Kwon and Lam constructed a resolution in terms of the Kac modules of the tensor module of $\mathfrak{gl}_{n|m}$. Taking the (conjectural) $q$-deformation of this resolution we have a complex which consists of modules $V_{\tilde{\nu}, \tilde{\mu}}$ with the cohomology $L_\lambda^{(n|m)}$. Multiplying by $L_\nu^{(n)} \otimes L_\mu^{(m)}$ we get a complex of $U_q \mathfrak{gl}_{n|m} \otimes U_q \mathfrak{gl}_n \otimes U_q \mathfrak{gl}_m$ modules. Then, applying the above equivalence we get a resolution of the conformal limit of $\mathcal{N}_{\mu, \nu, \lambda}^{n,m}(v)$ in terms of the conformal limits of $\mathcal{N}_{\tilde{\nu}, \nu, \tilde{\mu}}^{n,0}(v_1) \otimes \mathcal{N}_{\nu, \nu, \lambda}^{0,m}(v_2)$. This resolution should be a materialization of (2.4), its $q$-deformation was discussed above in Section 5.5.

The Euler characteristic of the resolution constructed in [8] yields the following formula

$$s_\lambda(x|y) = \sum_{\alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_r \geq r-m} (-1)^{\sum \alpha_i} s_{\pi + m - r, -\alpha}(x) s_{\alpha, \kappa}(y) \prod_{1 \leq i \leq n, 1 \leq j \leq m} \left(1 + \frac{y_j}{x_i}\right).$$

Here the notation $\pi$, $\kappa$ were introduced in Section 2.1. $s_\mu(x)$ is a Schur polynomial, i.e., the character of $L_\mu^{(m)}$ and $s_\lambda(x|y)$ is a hook Schur polynomial (or super-Schur polynomial), i.e., the character of $L_\lambda^{(n|m)}$. This formula resembles our character formula (2.4).

Remark 5.1. Moens and van der Jeugt in the paper [35] found another formula for the character of $L_\lambda^{(n|m)}$

$$s_\lambda(x|y) = \frac{(-1)^{mn-r}}{V(x_1, \ldots, x_n)V(y_1, \ldots, y_m)} \det \left(\begin{array}{ccc} 1 + \frac{y_j}{x_i} & \left(\sum_{a \geq 0} (-1)^a x_j^{-a-1+m} y_i^a\right) & \left(y_i^{Q_j}\right)_{1 \leq i \leq m, 1 \leq j \leq m-r} \\ x_j^{m+1} & 0 & \end{array}\right)_{1 \leq i \leq n-r, 1 \leq j \leq n}.$$

This formula is similar to our formula (2.3). It is natural to conjecture that there is a resolution which is a materialization of (5.22) and under the equivalence this resolution goes to a resolution which is a materialization of (2.3).

5Here we are a bit sloppy about parameter $v$ in $\mathcal{N}_{\mu, \nu, \lambda}^{n,m}(v)$, actually partition $\nu$ in $L_\nu^{(n)}$ can consist of noninteger parts with integer differences (instead of $\nu$ in $\mathcal{N}_{\mu, \nu, \lambda}^{n,m}(v)$) and total shift of these parts depends on $v$.
