IN Variant *-PRODUCTS ON COADJOINT ORBITS AND THE SHAPOVALOV PAIRING

A. ALEKSEEV AND A. LACHOWSKA

Abstract. We give an explicit formula for invariant *-products on a wide class of coadjoint orbits. The answer is expressed in terms of the Shapovalov pairing for generalized Verma modules.

1. Introduction

The problem of constructing a *-product on a manifold $M$ with given Poisson structure was formulated in [BFFLS]. In the case of symplectic manifolds the existence of *-products was established in [DL] and in a more geometric fashion in [F]. For general Poisson manifold the existence of *-products was proved in [K]. While general existence results are now available, giving explicit formulas for *-products remains a difficult task. The first formula of this type was given by Moyal in [M] in the case of a constant Poisson bi-vector on $\mathbb{R}^n$. Further examples that one can consider are linear Poisson brackets on the dual $\mathfrak{g}^*$ of the Lie algebra $\mathfrak{g}$, and non-degenerate Poisson brackets on coadjoint orbits in $\mathfrak{g}^*$. The *-products on $\mathfrak{g}^*$ were constructed in e.g. [G]. It is a natural idea to construct *-products on coadjoint orbits by restriction from $\mathfrak{g}^*$. However, in [CGR] it was proved that for $\mathfrak{g}$ semisimple a smooth *-product on $\mathfrak{g}^*$ does not restrict to coadjoint orbits.

Examples of *-products on some simple coadjoint orbits ($\mathbb{C}P^n$ and symmetric spaces) can be found e.g. in [BBEW], [T]. We shall concentrate on constructing *-products on $M$ invariant with respect to the transitive $G$-action. In the case of $G = \text{GL}(n)$ this problem has been addressed in [DM1]. Invariant *-products on minimal nilpotent coadjoint orbits of simple Lie groups were constructed in [ABC] and [AB]. In these works the locality axiom (stating that the *-product should be defined by a bi-differential operator) is relaxed. In the case of $\mathfrak{g}$ semisimple constructions of *-products on coadjoint orbits of semisimple elements were suggested in [A] using the deformation quantization with separation of variables of [Ka] and in [DM2] using the technique of the category theory.

Our main result is an explicit formula for invariant *-products on coadjoint orbits $G/H$ for which the corresponding Lie algebras $\mathfrak{g}$ and $\mathfrak{h}$ (or their complexifications) fit into a decomposition $\mathfrak{g} = \mathfrak{n}_+ \oplus \mathfrak{h} \oplus \mathfrak{n}_-$ (see Section 2.2 for the precise statement of assumptions). Examples include: the space $\mathbb{R}^{2n}$ with constant nondegenerate Poisson bracket (a coadjoint orbit in the dual to the Heisenberg algebra), coadjoint orbits of semisimple elements in semisimple Lie algebras, as well as infinite dimensional examples such as coadjoint orbits in the dual to the Virasoro algebra. Our construction is motivated by the fusion technique of [EV].

Date: October 6, 2003.
Acknowledgements. We received a lot of help from S. Parmentier who participated in this project in its early stages. We are grateful to S. Gutt, P. Etingof, V. Rubtsov, D. Sternheimer, X. Tang, B. Tsygan and P. Xu for the interest in our work and for useful discussions. This work was supported in part by the Swiss National Science foundation and by the Erwin Schrödinger Institute for mathematical Physics.

2. Preliminaries

2.1. Invariant *-products on homogeneous spaces. Let $M$ be a manifold. Recall that a *-product on $M$ is defined by a formal power series in $h$ with coefficients complex bi-differential operators on $M$, $B = \sum_{n=0}^{\infty} h^n B_n$ with $B_0 = 1$ and $B_n \in \text{Diff}^2(M)$. The *-product is then given by formula, $f \ast g := fg + \sum_{n=1}^{\infty} h^n B_n(f,g)$ for $f,g \in C^\infty(M)$. The main condition imposed on $B$ is that the *-product be associative, $f \ast (g \ast h) = (f \ast g) \ast h$ for all $f,g,h \in C^\infty(M)$.

Let $G$ be a connected Lie group and let $H \subset G$ be a closed Lie subgroup of $G$. Denote the corresponding Lie algebras by $\mathfrak{g}$ and $\mathfrak{h}$, respectively. The quotient $M := G/H$ carries a transitive action of $G$. There is an induced $G$-action on functions on $M$, and on differential and poly-differential operators. A *-product on $M$ is called invariant if it is defined by an invariant formal bi-differential operator $B$. That is, all bi-differential operators $B_n$ have to be $G$-invariant.

Recall that the space of invariant differential operators on $M = G/H$ can be expressed as follows, $\text{Diff}_G(M) = (U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^H$. Here $U\mathfrak{g}$ is the universal enveloping algebra of $\mathfrak{g}$, $U\mathfrak{g} \cdot \mathfrak{h}$ is the left ideal generated by $\mathfrak{h} \subset \mathfrak{g} \subset U\mathfrak{g}$. The algebra $U\mathfrak{g}$ carries a natural adjoint action of $H \subset G$, and since $\text{Ad}_H(\mathfrak{h}) = \mathfrak{h}$ this action factors to the quotient $U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h}$. The $H$-invariant part $(U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^H$ has an algebra structure induced by the one of $U\mathfrak{g}$. In a similar fashion, the space of invariant $N$-differential operators on $G/H$ is given by

$$\text{Diff}_G^N(M) = ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes N)^H,$$

where the invariant part is taken with respect to the diagonal $H$-action on $(U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes N$. Formal bi-differential operators which define invariant *-products on $M$ take values in the space

$$B \in ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes 2)^H[[h]].$$

Remark 2.1. As opposed to $\text{Diff}_G(M)$, the space $\text{Diff}_G^N(M)$ for $N > 1$ has no natural algebra structure.

Let $\Delta : U\mathfrak{g} \rightarrow U\mathfrak{g} \otimes U\mathfrak{g}$ be the standard coproduct of $U\mathfrak{g}$. That is, $\Delta$ is an algebra homomorphism such that $\Delta(x) = 1 \otimes x + x \otimes 1$ for all $x \in \mathfrak{g}$. Let $B,C \in \text{Diff}_G^2(M) = ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes 2)^H$. Then expressions $((\Delta \otimes 1)B)(C \otimes 1)$ and $((1 \otimes \Delta)B)(1 \otimes C)$ define unique elements of $\text{Diff}_G^2(M) = ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes 3)^H$. In more detail, let $B,C \in U\mathfrak{g} \otimes U\mathfrak{g}$ be representatives of the classes $B,C \in (U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes 2$. The classes of $((\Delta \otimes 1)B)(C \otimes 1)$ and $((1 \otimes \Delta)B)(1 \otimes C)$ in $(U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h})^\otimes 3$ are $H$-invariant and independent of the choice.

The associativity of an invariant *-product defined by a formal bi-differential operator $B$ is expressed by the following equality of invariant formal 3-differential operators,

$$((\Delta \otimes 1)B)(B \otimes 1) = ((1 \otimes \Delta)B)(1 \otimes B).$$

in \(((U \mathfrak{g}/U \mathfrak{g} \cdot \mathfrak{h})^\mathbb{C})^H[[h]]\).

**Remark 2.2.** If \(H\) is a connected Lie group one can replace the condition of \(Ad_H\)-invariance of \(B\) by an algebraic condition of invariance with respect to the adjoint action of \(\mathfrak{h}\). It is also a natural context when the Lie algebra \(\mathfrak{g}\) is infinite dimensional and the corresponding Lie group may not be available.

**Remark 2.3.** In the case of \(\mathfrak{h} = 0\) equation (1) was considered by Drinfeld in [Dr]. In this reference a family of solutions of (1) was constructed in terms of the Campbell-Hausdorff series for the Lie algebra \(\mathfrak{g}\).

### 2.2. Assumptions on \(\mathfrak{g}\) and \(\mathfrak{h}\).

**Examples.** Here we list assumptions imposed on the Lie algebra \(\mathfrak{g}\) and its Lie subalgebra \(\mathfrak{h}\) which allow to construct explicit solutions of equation (1).

- The Lie algebra \(\mathfrak{g}\) is \(\mathbb{Z}\)-graded, \(\mathfrak{g} = \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}_i\), such that each graded component has finite dimension. The adjoint action of \(H\) on \(\mathfrak{g}\) preserves this grading. Let \(\mathfrak{h} = \mathfrak{g}_0\) and denote \(\mathfrak{n}_+ = \mathfrak{g}_{>0}, \mathfrak{n}_- = \mathfrak{g}_{<0}\).

- There exists a character \(\chi : \mathfrak{g}_0 \rightarrow \mathbb{C}\) such that the paring \(\mathfrak{n}_+ \times \mathfrak{n}_- \rightarrow \mathbb{C}\) defined by \(u, v \mapsto \chi([u, v]_0)\) for \(u \in \mathfrak{n}_+, v \in \mathfrak{n}_-\) is nondegenerate. Here \(x \mapsto x_0\) denotes the projection onto the zero graded component \(\mathfrak{g}_0\). Such a character is called nonsingular.

**Remark 2.4.** If \(H\) is connected, the requirement that \(H\) preserves the grading is automatically satisfied.

**Remark 2.5.** The second assumption implies that \(\mathfrak{g}_0 \neq 0\).

**Example 2.6.** Assume that \(\mathfrak{g}\) is quadratic. That is, there is a nondegenerate \(\text{ad}(\mathfrak{g})\)-invariant symmetric bilinear form \(Q : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathbb{C}\) of degree zero. In this case, \(\mathfrak{g}_0\) is a finite dimensional quadratic Lie algebra with invariant bilinear form the restriction of \(Q\) to \(\mathfrak{g}_0\). Let \(\mathfrak{z}(\mathfrak{g}_0)\) be the center of \(\mathfrak{g}_0\). Every element \(z \in \mathfrak{z}(\mathfrak{g}_0)\) defines a character \(\chi_z\) of \(\mathfrak{g}_0\), \(\chi_z(x) = Q(z, x)\). An element \(z \in \mathfrak{z}(\mathfrak{g}_0)\) is called nonsingular if the map \((u, v) \mapsto \chi_z([u, v]_0)\) for \(u \in \mathfrak{n}_+, v \in \mathfrak{n}_-\) is nondegenerate. Here \(x \mapsto x_0\) denotes the projection onto the zero graded component \(\mathfrak{g}_0\). Such a character is called nonsingular.

**Example 2.7.** Let \(\mathfrak{g}\) be a semisimple complex Lie algebra, \(\mathfrak{h}\) be a Cartan subalgebra of \(\mathfrak{g}\), \(\Pi = \{\alpha_i\}_{i=1}^{\text{rank}(\mathfrak{g})}\) be (some choice of) the set of simple roots. The principal grading on \(\mathfrak{g}\) is the unique grading such that \(\mathfrak{h} = \mathfrak{g}_0\) and all root vectors corresponding to simple roots have degree 1, \(e_{\alpha_i} \in \mathfrak{g}_1\). Any regular character \(\chi\) of \(\mathfrak{h}\) defines a nondegenerate paring \(\mathfrak{n}_+ \times \mathfrak{n}_- \rightarrow \mathbb{C}\).

This construction applies verbatim to any Kac-Moody algebra.

**Example 2.8.** Let \(\mathfrak{g}\) be a semisimple complex Lie algebra, and let \(z \in \mathfrak{g}\) be a semisimple element. Let \(\mathfrak{g}_z\) be the centralizer of \(z\) and let \(\mathfrak{h}\) be a Cartan subalgebra of \(\mathfrak{g}\) such that \(z \in \mathfrak{h} \subset \mathfrak{g}_z\). Define the unique grading on \(\mathfrak{g}\) such that \(\mathfrak{g}_0 = \mathfrak{g}_z\) and for all simple roots in \(S_z := \{\alpha_i, e_{\alpha_i} \notin \mathfrak{g}_z\}\) one has \(e_{\alpha_i} \in \mathfrak{g}_1\). The Lie algebra \(\mathfrak{p}_+ = \mathfrak{g}_0 \oplus \mathfrak{n}_+\) is a parabolic subalgebra of \(\mathfrak{g}\) with the Levi subalgebra \(\mathfrak{g}_z\), corresponding to the subset \(S_z \subset \Pi\). The center \(\mathfrak{z}(\mathfrak{g}_0) \subset \mathfrak{h}\) consists of the elements orthogonal to \(S_z\). Denote by \(R\) the set of roots of \(\mathfrak{g}\) and by \(R_z \subset R\) the set of roots of \(\mathfrak{g}_z\). Then the nonsingular elements of \(\mathfrak{z}(\mathfrak{g}_0)\) that define nondegenerate bilinear paring between \(\mathfrak{n}_+\) and \(\mathfrak{n}_-\) are those with nonvanishing scalar product with all elements of \(R \setminus R_z\). They form a Zariski open subset of \(\mathfrak{z}(\mathfrak{g}_0)\). In particular \(z\) is a central nonsingular element in \(\mathfrak{z}(\mathfrak{g}_0)\).

If \(z\) is a regular semisimple element of \(\mathfrak{g}\) we return to Example 2.7.
Example 2.9. Let $\mathfrak{g} = H_n$ be the Heisenberg Lie algebra generated by $c$ and by $p_i, q_i, i = 1 \ldots n$ with the only nonvanishing Lie brackets $[p_i, q_j] = \delta_{ij}c$. Define the grading by setting $\text{deg}(p_i) = 1, \text{deg}(q_i) = -1$ and $\text{deg}(c) = 0$. Then $\mathfrak{g}_0 = \mathbb{C}c$ and any $\chi \in (\mathfrak{g}_0)^*$ such that $\chi(c) \neq 0$ is a nonsingular character.

Example 2.10. Let $\mathfrak{g} = \text{Vir}$ be the Virasoro algebra with $\mathfrak{g}_n = \mathbb{C}L_n, n \in \mathbb{Z}, n \neq 0$ and $\mathfrak{g}_0 = \mathbb{C}L_0 \oplus \mathbb{C}c$ with the Lie bracket $[L_n, L_m] = (n-m)L_{n+m} + \delta_{n+m,0}\frac{n^3-n}{12}c$. Let $\chi \in \mathfrak{g}_0^*$ be defined so that $\chi(L_0) = \Delta, \chi(c) = c$ for some $\Delta, c \in \mathbb{C}$. Then $\chi$ defines the pairing $(L_n, L_{-n}) = 2n\Delta + \frac{n^3-n}{12}c$ which is nondegenerate for all pairs $\Delta, c \in \mathbb{C}$ such that $\Delta + \frac{n^3-n}{12}c \neq 0$ for all $n \in \mathbb{Z}_{>0}$.

2.3. Relation to coadjoint orbits. Let $\mathfrak{g}^* := \bigoplus_{i \in \mathbb{Z}} \mathfrak{g}_i^*$ be the (graded) dual to the Lie algebra $\mathfrak{g}$. It carries a natural coadjoint action of $\mathfrak{g}$. An element $\chi \in \mathfrak{g}_0^0 \subset \mathfrak{g}^*$ defines a point in $\mathfrak{g}^*$. Our second assumption is equivalent to saying that $\mathfrak{g}_0$ is the coadjoint stabilizer of $\chi$.

Assume that $\mathfrak{g}$ is finite dimensional. Then there is a connected simply connected Lie group $G$ with Lie algebra $\mathfrak{g}$ and with a natural coadjoint action of $G$ on $\mathfrak{g}^*$. Denote the stabilizer of $\chi$ by $G_0 \subset G$. It is a closed subgroup of $G$ with Lie algebra $\mathfrak{g}_0$. A coadjoint orbit of $\chi$ under the $G$-action is a homogeneous space $M = G/G_0$. Our construction of invariant $*$-products applies if the adjoint action of $G_0$ preserves the grading. If $G_0$ is connected, this condition is satisfied automatically. In particular, this is always the case if $\mathfrak{g}$ is a semisimple Lie algebra.

If $G_0$ is disconnected let $H$ be the connected component of the unit element. Then our method applies to $G/H$ which covers the coadjoint orbit $G/G_0$.

Let $G$ be a real Lie group and $\mathfrak{g}$ be the corresponding real Lie algebra. Since the $*$-products are usually defined on the space of complex valued functions, it is sufficient that assumptions of the previous Section be satisfied for the complexified Lie algebra $\mathfrak{g}^C$. For this reason in the rest of the paper we assume that $\mathfrak{g}$ is a complex Lie algebra.

Recall that the coadjoint orbits carry an invariant symplectic form which is constructed as follows. Identify $T_{\omega}H(G/H) \cong \mathfrak{n}_- \oplus \mathfrak{n}_+$, and define $\omega(u, v) := -\chi([u, v])$. By assumptions, this bilinear form establishes a duality between $\mathfrak{n}_-$ and $\mathfrak{n}_+$. Let $u_i$ and $v_i$ be a pair of dual bases in $\mathfrak{n}_-$ and $\mathfrak{n}_+$, respectively. Then, the inverse of $\omega$ is the invariant Kirillov-Kostant-Souriau Poisson bi-vector on $G/H$ which is equal to $\sum_i u_i \wedge v_i$ at $\mathfrak{e}H$. An additional constraint which is often imposed on the bi-differential operator $B$ is that the skew-symmetric part of $B_1$ be equal a given Poisson bi-vector. In our case, this condition reads

$$B_1 - B_1' = \sum_i u_i \wedge v_i,$$

where $B_1'$ is a bi-differential operator obtained by exchanging two copies of $U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{h}$ in the tensor product. Geometrically, $\mathfrak{n}_-$ and $\mathfrak{n}_+$ define two distributions in $T(G/H)$. If we deal with a real Lie group $\mathfrak{g}$ and the conditions of the previous Section are satisfied for the real Lie algebra $\mathfrak{g}$, these distributions give rise to transverse Lagrangian polarizations on the orbit. In general, we are getting transverse complex polarizations.

3. Generalized Verma modules and the Shapovalov pairing

In this Section we recall the notion and basic properties of the Shapovalov pairing and of the associated canonical element in the tensor product of two opposite generalized Verma modules. The details on the generalized Verma modules can be found in e.g. [Di].
3.1. **Generalized Verma modules.** Let \( p_+ = \bigoplus_{i \geq 0} \mathfrak{g}_i \) and \( p_- = \bigoplus_{i < 0} \mathfrak{g}_i \). A central character \( \chi \) of \( \mathfrak{g}_0 \) can be given a \( p_\pm \)-module structure by letting \( n_\pm \) act on it by zero. Define the generalized Verma modules by

\[
M^\pm = \text{Ind}^U_{U p_\pm} \chi \cong U(\mathfrak{g}) \otimes_{U p_\pm} \chi.
\]

In Example 2.7 we recover the Verma module over \( \mathfrak{g} \) of highest weight \( \chi \), in Example 2.8 - the scalar generalized Verma module induced from the parabolic \( p_+ \). By general properties of the induction, \( M^+ \) is isomorphic to \( U n_- \) as a \( U n_- \)-module generated by \( v_{\chi} = 1 \otimes \chi \). Similarly, \( M^- \cong U n_+ \) as a \( U n_+ \)-module generated by \( v_{\chi} \). Both Verma modules inherit natural gradings from \( U n_+, U n_- \).

Suppose that \( M \) is a \( \mathbb{Z} \)-graded \( U(\mathfrak{g}) \)-module, and \( V \) is any \( U(\mathfrak{g}) \)-module. Then we define the completed tensor product \( M \otimes V \equiv \bigoplus_{i \in \mathbb{Z}} M_i \otimes V \) as a \( \mathbb{Z} \)-graded \( U(\mathfrak{g}) \)-module where elements of \( U(\mathfrak{g}) \) act by comultiplication. In particular, if both \( M \) and \( N \) are \( \mathbb{Z} \)-graded \( U(\mathfrak{g}) \)-modules, then \( M \otimes N \) has two \( \mathbb{Z} \)-gradings. Often it is convenient to preserve both gradings, \( M \otimes N \equiv \bigoplus_{i,j} M_i \otimes N_j \), where the elements may have infinite length.

Fix a nonsingular character \( \chi \) of \( \mathfrak{g}_0 \). For any \( \lambda \in \mathbb{C} \) we consider a rescaled character \( \lambda \chi := \lambda \chi \), and define a paring between \( U n_- \) and \( U n_+ \), which depends on the parameter \( \lambda \). Write \( U(\mathfrak{g}) \cong U(\mathfrak{g}_0) \oplus (n_- U(\mathfrak{g}) \oplus U(\mathfrak{g}) n_+) \) and let \( \phi : U(\mathfrak{g}) \rightarrow U(\mathfrak{g}_0) \) be the projection of an element in \( U(\mathfrak{g}) \) to the first summand along the second. For any \( x \in U n_- \), \( y \in U n_+ \), we set

\[
(x, y)_\chi := \lambda \chi (\phi(S(y)x)),
\]

where \( S : U \mathfrak{g} \rightarrow U \mathfrak{g} \) is the antipode of \( U \mathfrak{g} \). That is, \( S \) is the unique anti-automorphism of \( U \mathfrak{g} \) such that \( S(x) = -x \) for all \( x \in \mathfrak{g} \).

Let \( M^+_\lambda \equiv \text{Ind}^U_{U p_+} \chi \lambda \) and \( M^-_\lambda \equiv \text{Ind}^U_{U p_-} \chi - \lambda \) be the generalized Verma modules. The pairing \( \langle \cdot, \cdot \rangle_\lambda \) gives rise to a pairing between \( M^+_\lambda \) and \( M^-_\lambda \). Namely, fix generating vectors \( v_\lambda = 1 \otimes \chi \) in \( M^+_\lambda \) and \( v_{-\lambda} = 1 \otimes \chi - \lambda \) in \( M^-_\lambda \) and let

\[
(xv_\lambda, yv_{-\lambda}) := (x, y)_\lambda.
\]

This pairing is called the Shapovalov pairing between the generalized Verma modules. It is \( U \mathfrak{g} \)-invariant in the following sense: \( (au, v) = (u, S(a)v) \) for \( u \in M^+_\lambda \) and \( v \in M^-_\lambda \). The modules \( M^+_\lambda \) and \( M^-_\lambda \) are irreducible if and only if \( \langle \cdot, \cdot \rangle_\lambda : U n_+ \times U n_- \rightarrow \mathbb{C} \) is nondegenerate. Indeed, if \( x \cdot v_\lambda \) lies in a proper submodule of \( M^+_\lambda \) and \( x \in U n_- \) has a maximal degree in this submodule, then \( (x, y)_\lambda = 0 \) for all \( y \in U n_+ \) by the \( U(\mathfrak{g}) \)-invariance of the paring, and conversely.

**Proposition 3.1.** Let \( \chi \) be a nonsingular character of \( \mathfrak{g}_0 \). Then the pairing \( \langle \cdot, \cdot \rangle_\lambda : U n_- \otimes U n_+ \rightarrow \mathbb{C} \) is nonsingular for almost all \( \lambda \in \mathbb{C} \).

**Proof.** Let \( \{ u_i \} \) be a homogeneous basis in \( n_- \), \( \chi \) a nonsingular character, and \( \{ v_i \} \) the dual basis in \( n_+ \) with respect to the paring \( (u, v) = -\chi(|u, v|) \). Choose an order of the elements \( u_i \) in each graded component of \( n_+ \), and enumerate the set \( \{ u_i \} \) by increased grading. Then we have a PBW-type basis in \( U(n_+) \). In particular, in each graded component \( (U n_-)_n, n \in \mathbb{Z}_+ \), there is a basis \( \{ x_k^{(n)} \}_{k=1}^N \) of monomials in \( \{ u_i \} \). It can be ordered so that the number of factors in \( x_k^{(n)} \) is greater or equal to that in \( x_j^{(n)} \) whenever \( i \leq j \). For each element \( x_k^{(n)} = u_{k_1}^{(n)} u_{k_2}^{(n)} \cdots u_{k_r}^{(n)} \), set \( y_k^{(n)} = v_{k_1} s_{k_2} \cdots v_{k_r} s_{k_r} \). The elements \( \{ y_k^{(n)} \} \) form a basis in \( (U n_+)_n \). The number \( d_k = \sum_{i=1}^r s_i \)
will be called the length of \( x_k^{(n)} \). Let \( \lambda \in \mathbb{C} \) and consider the \( N \times N \) matrix \( M^n(\lambda) = (x_k^{(n)}, y_l^{(n)})_\lambda \). Its elements are polynomials in \( \lambda \). The following statements are easy to check:

(a) The degree of the polynomial \( (x_k^{(n)}, y_l^{(n)}) \) cannot exceed the length of the shortest of the two monomials \( x_k^{(n)}, y_l^{(n)} \).

(b) For two monomials \( x_k^{(n)}, y_l^{(n)} \) of the same length \( d_k \), \( (x_k^{(n)}, y_l^{(n)}) \) is a polynomial of degree strictly less than \( d_k \) unless \( l = k \). If \( l = k \) then \( x_k^{(n)} \) and \( y_k^{(n)} \) have the same number of factors which are dual to each other with respect to the \( (\cdot, \cdot) \) pairing.

(c) We have

\[
(x_k, y_k)_{\lambda} = \left( \prod_{i=1}^r (s_i) ! \right) \lambda^{d_k} + P_k(\lambda),
\]

where \( P_k \) is a polynomial of degree less than \( d_k \).

The above implies that we can write

\[
M^n(\lambda) = D^n(\lambda)C(1 + O(1/\lambda)),
\]

where \( D^n(\lambda) \) is a diagonal matrix with \( [D^n(\lambda)]_{kk} = \left( \prod_{i=1}^r (s_i) ! \right) \lambda^{d_k} \), the matrix \( C \) is constant lower triangular with units on the diagonal, and \( O(1/\lambda) \) is a matrix whose entries are polynomials in \( 1/\lambda \) without a constant term. The determinant of \( M^n(\lambda) \) is a polynomial in \( \lambda \) of degree \( \sum_{k=1}^N d_k \) with a nonzero leading coefficient. Therefore, the matrix \( M^n(\lambda) \) is invertible for all but a finite number of values of \( \lambda \in \mathbb{C} \). The union of zeros of \( M^n(\lambda) \) for all \( n \) is a countable subset of \( \mathbb{C} \). This completes the proof.

3.2. **Canonical element** \( F_\lambda \). Let \( \lambda \in \mathbb{C} \) such that the pairing \( (\cdot, \cdot)_\lambda \) be nonsingular. Denote by \( F_\lambda \in U_{\mathfrak{n}_-} \hat{\otimes} U_{\mathfrak{n}_+} \) the canonical element corresponding to the pairing. It has the following form, \( F_\lambda \in 1 + (U_{\mathfrak{n}_-})_{<0} \hat{\otimes} (U_{\mathfrak{n}_+})_{>0} \). Let \( M_\lambda^+ \hat{\otimes} M_\lambda^- \) be a completed tensor product of two irreducible generalized Verma modules with generating vectors \( v_\lambda \) and \( v_{-\lambda} \). Then \( F_\lambda(v_\lambda \otimes v_{-\lambda}) \) is the canonical element with respect to the Shapovalov pairing. In particular, it is \( U_{\mathfrak{g}} \)-invariant. Choose a generating vector \( v \in V_0 \), in the trivial \( U_{\mathfrak{g}} \) module \( V_0 \cong \mathbb{C} \). Then \( v \mapsto F_\lambda(v_\lambda \otimes v_{-\lambda}) \) defines a \( U_{\mathfrak{g}} \)-homomorphism \( V_0 \to M_\lambda^+ \hat{\otimes} M_\lambda^- \).

**Proposition 3.2.** The element \( F_\lambda \) is a meromorphic function of \( \lambda \) which is holomorphic at \( \lambda = \infty \). The residue of \( F_\lambda \) at \( \lambda = 0 \) is given by formula,

\[
\text{Res}_{\lambda=0} F_\lambda = \sum_{i=1}^n u_i \otimes v_i \in \mathfrak{n}_- \hat{\otimes} \mathfrak{n}_+ \subset U_{\mathfrak{n}_-} \hat{\otimes} U_{\mathfrak{n}_+}.
\]

**Proof.** Using bases \( \{x_k^{(n)}\} \) and \( \{y_k^{(n)}\} \) of Proposition 3.1 one can write the element \( F_\lambda \) in the following form,

\[
F_\lambda = \sum_{n=0}^{\infty} \sum_{k,l} (M^n(\lambda))^{-1}_{lk} x_k^{(n)} \otimes y_l^{(n)}.
\]

Decomposition (3) implies that matrix elements \( (M^n(\lambda))^{-1}_{lk} \) are rational functions of \( \lambda \) holomorphic at \( \lambda = \infty \). Hence, each bi-graded component of \( F_\lambda \) is a rational function of \( \lambda \) holomorphic at \( \lambda = \infty \), which amounts to saying that \( F_\lambda \) is meromorphic and regular at \( \lambda = \infty \).
To compute the residue of $F_\lambda$ note that for the matrix $C$ of (3) one has $C_{kl} = \delta_{kl}$ for $k, l$ with $d_k = d_l = 1$. This implies the same property for the inverse matrix, $C_{kl}^{-1} = \delta_{kl}$ for $k, l$ with $d_k = d_l = 1$. We write,

$$\text{Res}_{\lambda=0} \left( M^n(\lambda) \right)_{lk}^{-1} = \text{Res}_{\lambda=0} \sum_m (1+O(\lambda^{-1}))_{lm} C_{mk}^{-1} \lambda^{-dk} (\prod_i s_i!)^{-1} = \text{Res}_{\lambda=0} C_{lk}^{-1} \lambda^{-dk} (\prod_i s_i!)^{-1}$$

This formula shows that the residue vanishes unless $d_k = 1$. Then, since $C^{-1}$ is lower triangular with $d_l \leq d_k$ for $l \geq k$ one has $d_l = 1$ as well. Hence, the only matrix elements which have nonvanishing residues are diagonal entries $k = l$ with $d_k = 1$, in which case the residue is equal to one. Since the elements with $d = 1$ are basis elements in $\mathfrak{n}_-$ and $\mathfrak{n}_+$ we obtain (4) as required.

**Remark 3.3.** Formula (3) implies that the coefficient $(M^n(\lambda))_{lk}^{-1}$ in front of the element $x_k^{(n)} \otimes y_l^{(n)}$ in $F_\lambda$ is a rational function in $\lambda$ of the order less or equal to $-dk$. By exchanging the roles of $k$ and $l$ we see that in fact the order is $\leq \max(d_k, d_l)$.

**Remark 3.4.** In case when $\mathfrak{g}$ is finite dimensional, $F_\lambda$ has only finitely many bi-graded components of a given degree $m$ in $1/\lambda$. Indeed, suppose $(\mathfrak{n}_+)_{l} = 0$ for all $l > d_{\max}$. Then we have the following estimate for the length $d_k$ of monomials in the basis of $(\mathfrak{U}\mathfrak{n}_+)_n$: $d_k \geq \left\lceil \frac{n}{d_{\max}} \right\rceil$. Therefore, the power of $\lambda$ in the matrix $M^n(\lambda)$ cannot be less than $\left\lceil \frac{n}{d_{\max}} \right\rceil$. This means that the Taylor’s series in $1/\lambda$ with leading term of degree $m$ can appear only in matrices $(M^n(\lambda))^{-1}$ with $n \leq md_{\max}$. Since each graded component of $\mathfrak{U}\mathfrak{n}_+$ is finite dimensional, we get only finitely many elements in the decomposition of $F_\lambda$ with coefficients of a given degree in $1/\lambda$.

## 4. Solutions of the associativity equation

In this Section we relate the Shapovalov pairing with the associativity equation (1) for the pair $\mathfrak{g}, \mathfrak{h} := \mathfrak{g}_0$. In the proof of the associativity equation we shall use $\mathfrak{U}\mathfrak{g}$-homomorphisms from generalized Verma modules to various completed tensor products. Our argument uses the method introduced in [EV]; detailed exposition can be found in [ES].

### 4.1. $\mathfrak{U}\mathfrak{g}$-homomorphisms of generalized Verma modules

One useful property of $\mathfrak{U}\mathfrak{g}$-homomorphisms is given in the following Proposition.

**Proposition 4.1.** Let $M_\lambda^+$ be an irreducible generalized Verma module with generating vector $v_\lambda$. Suppose that for a $\mathfrak{U}\mathfrak{g}$-module $\mathcal{V}$, there exists a $\mathfrak{U}\mathfrak{g}$-invariant element $z \in M_\lambda^+ \otimes \mathcal{V}$ such that $z \in v_\lambda \otimes w + (\mathfrak{U}\mathfrak{n}_-)_{<0} \cdot v_\lambda \otimes \mathcal{V}$ for a certain $w \in \mathcal{V}$. Then such element is unique.

**Proof.** Assuming that an invariant element exists, we will construct it inductively starting from the summand $v_\lambda \otimes w$. Let $\{y_k\}$ and $\{x_k\}$ be the bases in $\mathfrak{U}\mathfrak{n}_+$ and $\mathfrak{U}\mathfrak{n}_-$ which consist of the elements of the bases in each graded component of $\mathfrak{U}\mathfrak{n}_+$ and $\mathfrak{U}\mathfrak{n}_-$ constructed in the proof of Proposition 3.1, and ordered by the increased grading. Then we can write $z = v_\lambda \otimes w + \sum_{k>0} x_k v_\lambda \otimes w_k$ for some elements $w_k \in \mathcal{V}$. By assumptions we have $\Delta(y_k)z = 0$ for all $k > 0$. Let $y_1$ be a basis element of degree 1. Then $\Delta(y_1)z = v_\lambda \otimes y_1 w + \sum_k y_1 x_k v_\lambda \otimes w_k + \sum x_k v_\lambda \otimes y_1 w_k$. By construction of the basis, there is only one $x_s$ (of degree 1) such that $y_1 x_s v_\lambda = v_\lambda$, and therefore one determines uniquely the element $w_s \in \mathcal{V}$. Then proceed by induction on the degree of $y_k$. □
Remark 4.2. In case when \( V = V \) is a finite dimensional module, \( \otimes \) is the usual tensor product, the statement follows from the Frobenius reciprocity of the induction:

\[
\text{Hom}_{Ug}(V_0, M^+_\lambda \otimes V) = \text{Hom}_{Ug}(M^-_{-\lambda}, V) = \text{Hom}_{Ug}(\chi_{-\lambda}, V).
\]

Therefore, the space of \( Ug \)-homomorphisms \( V_0 \to M^+_\lambda \otimes V \) coincides with the space of \( (Un_-) \)-invariant vectors in \( V \) with the action of \( Ug_0 \) given by the character \( \chi_{-\lambda} \).

**Proposition 4.3.** Let \( A : g \to g \) be a Lie algebra automorphism of \( g \) preserving the grading. Then the element \( F_\lambda \) is invariant with respect to the natural action of \( A \) on \( Un_- \otimes Un_+ \).

**Proof.** Since \( A \) preserves the grading, the element \( A(F_\lambda)(v_\lambda \otimes v_{-\lambda}) \in M^+_\lambda \otimes M^-_{-\lambda} \) is of the form, \( v_\lambda \otimes v_{-\lambda} + (Un_-)_{<0} \cdot v_\lambda \otimes (Un_+)_{>0} \cdot v_{-\lambda} \). The map \( A \) being a Lie algebra automorphism, \( A(F_\lambda)(v_\lambda \otimes v_{-\lambda}) \) is \( Ug \)-invariant. Hence, by Proposition 4.1 one has \( A(F_\lambda)(v_\lambda \otimes v_{-\lambda}) = F_\lambda(v_\lambda \otimes v_{-\lambda}) \) which implies \( A(F_\lambda) = F_\lambda \). \( \square \)

**Remark 4.4.** Assume that \( g \) integrates to a Lie group \( G \), and \( H \subset G \) is a subgroup with Lie algebra \( g_0 \) such that \( Ad_H \) preserves the grading. Then, the element \( F_\lambda \) is \( Ad_H \)-invariant.

**Proposition 4.5.** Let \( \lambda \in \mathbb{C} \) be such that the module \( M^+_\lambda \) is irreducible and denote \( p : Ug \to Ug/ Ug \cdot g_0 \) the natural projection. Then

\[
(1 \otimes p \otimes 1) [(\Delta \otimes 1) F_\lambda (F_\lambda \otimes 1)] = (1 \otimes p \otimes 1) [(1 \otimes \Delta) F_\lambda (1 \otimes F_\lambda)]
\]

in \( Un_- \otimes Ug/ Ug \cdot g_0 \otimes Un_+ \).

**Remark 4.6.** In case when \( g \) is semisimple and \( g_0 \) its Cartan subalgebra, the equation (5) is a projection from \( U(g) \otimes D \) to \( Un_- \otimes Ug/ Ug \cdot g_0 \otimes Un_+ \) of the dynamical cocycle condition which was considered in [EV], [EE] and [ESS]. The element satisfying such a condition is called a dynamical twist and is used further to construct solutions of the dynamical Yang-Baxter equation.

For \( V_0 \) the trivial representation of \( Ug \) define \( V_0 = \text{Ind}_{Ug_0} Ug_0 \). Choose a nonzero vector \( v \in V_0 \) and denote \( \tilde{v} := 1 \otimes v \) the generating vector in \( V_0 \).

**Lemma 4.7.** Let \( \lambda \in \mathbb{C} \) be such that the module \( M^+_\lambda \) is irreducible.

(a) There exists a unique \( Ug \)-homomorphism

\[
F^+_\lambda : M^+_\lambda \to M^+_\lambda \otimes V_0
\]

such that

\[
F^+_\lambda(v_\lambda) \in v_\lambda \otimes \tilde{v} + (Un_-)_{<0} \cdot v_\lambda \otimes Ug \cdot \tilde{v}.
\]

Explicitly,

\[
F^+_\lambda(v_\lambda) = F_\lambda(v_\lambda \otimes \tilde{v}).
\]

(b) Similarly, there exists a unique \( Ug \)-homomorphism

\[
F^-_\lambda : M^-_{-\lambda} \to V_0 \otimes M^-_{-\lambda}
\]

such that for a fixed vector \( v \in V_0 \)

\[
F^-_\lambda(v_{-\lambda}) \in \tilde{v} \otimes v_{-\lambda} + Ug \cdot \tilde{v} \otimes (Un_+)_{>0} \cdot v_{-\lambda}.
\]

Explicitly,

\[
F^-_\lambda(v_{-\lambda}) = F_\lambda(\tilde{v} \otimes v_{-\lambda}).
\]
Proof. Consider the first statement. The element \( F_\lambda(v_\lambda \otimes \bar{v}) \) is \( U\mathfrak{n}_+ \)-invariant because of the \( U\mathfrak{g} \)-invariance of the Shapovalov’s paring and the \( U\mathfrak{n}_- \)-invariance of \( v_\lambda \). The subalgebra \( U\mathfrak{g}_0 \) acts on \( F_\lambda(v_\lambda \otimes \bar{v}) \) by the character \( \chi_\lambda \). Therefore, by the universal property of the generalized Verma module, there is a homomorphism \( \mathcal{F}_\lambda^+ : M_\lambda^+ \to M_\lambda^+ \otimes V_0 \) mapping the generating vector \( v_\lambda \) to \( F_\lambda(v_\lambda \otimes \bar{v}) \). The proof of the uniqueness for a given choice of \( v \in V_0 \) coincides verbatim with the proof of Proposition 4.1. The second statement is proved similarly. \( \square \)

Lemma 4.8. Let \( \lambda \in \mathbb{C} \) be such that \( M_\lambda^+ \) is irreducible. The two morphisms of \( U\mathfrak{g} \)-modules

\[
V_0 \to M_\lambda^+ \otimes M_{-\lambda} \xrightarrow{\mathcal{F}_\lambda^+ \otimes \text{id}} M_\lambda^+ \otimes V_0 \otimes M_{-\lambda}
\]

and

\[
V_0 \to M_\lambda^+ \otimes M_{-\lambda} \xrightarrow{\text{id} \otimes \mathcal{F}_\lambda^-} M_\lambda^+ \otimes V_0 \otimes M_{-\lambda}
\]

coincide.

Proof. Both homomorphisms map \( v \) to \( v_\lambda \otimes \bar{v} \otimes v_{-\lambda} + (U\mathfrak{n}_-)_{<0} \cdot v_\lambda \otimes \bar{U}(\mathfrak{g}) \cdot \bar{v} \otimes (U\mathfrak{n}_+)_{>0} \cdot v_{-\lambda} \). Such a homomorphism is unique by Lemma 4.7. \( \square \)

Proof of Proposition 4.5. Written in terms of \( F_\lambda \in \sum_i (U\mathfrak{n}_-)_{-i} \otimes (U\mathfrak{n}_+)_i \), the equality of the two homomorphisms in Lemma 4.8 gives the statement of the theorem. \( \square \)

4.2. Invariant \( * \)-products. Denote by \( \pi : U\mathfrak{g}^\otimes 2 \to (U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{g}_0)^\otimes 2 \) the natural projection. The following theorem is the main result of this paper.

Theorem 4.9. Let \( \chi \) be a nonsingular character of \( \mathfrak{g}_0 \) and \( F_\lambda \) be the corresponding canonical element in \( U\mathfrak{n}_- \otimes U\mathfrak{n}_+ \). Then, the element \( B := \pi(F_{h^{-1}}) \) takes values in \( ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{g}_0)^\otimes 2)^\oplus [\hbar] \) and satisfies the associativity equation (1).

Proof. Recall that \( F_\chi \) is a meromorphic function of \( \chi \) holomorphic at \( \chi = \infty \). Hence, \( F_{\mu-1} \) is holomorphic at zero and defines a formal power series \( F_{h^{-1}} \in (U\mathfrak{n}_- \otimes U\mathfrak{n}_+)[[\hbar]] \) with projection \( B := \pi(F_{h^{-1}}) \in (U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{g}_0)^\otimes 2[[\hbar]] \). The \( U\mathfrak{g} \)-invariance of the Shapovalov paring implies the \( \mathfrak{g}_0 \)-invariance of \( \pi(F_\chi) \) and as a consequence the \( \mathfrak{g}_0 \)-invariance of \( B \).

Projecting equation (5) to \( (U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{g}_0)^\otimes 3 \) yields the associativity equation for \( \pi(F_\chi) \). Since the latter is holomorphic at infinity, the associativity equation for \( B \) follows. \( \square \)

Remark 4.10. As usual, assume that \( \mathfrak{g} \) integrates to a Lie group \( G \) and \( \mathfrak{g}_0 \) integrates to a subgroup \( H \subset G \) such that \( \text{Ad}_H \) preserves the grading. Then \( \pi(F_\chi) \) is an element in \( ((U\mathfrak{g}/U\mathfrak{g} \cdot \mathfrak{g}_0)^\otimes 2)^H[[\hbar]] \) which satisfies the associativity equation. Hence, it defines an invariant \( * \)-product on \( G/H \).

Remark 4.11. In a recent paper [DM2], a categorical approach to constructing dynamical twists is developed. It allows the authors to obtain a quantization of function algebras on semisimple coadjoint orbits for \( \mathfrak{g} \) reductive and \( \mathfrak{g}_0 \) its Levi subalgebra. The difference between the approach of [DM2] and the one chosen in the present paper is that we do not use finite dimensional representations of \( U\mathfrak{g} \) and the harmonic analysis on \( G/H \).

Proposition 4.12. Let \( \{u_i\} \) and \( \{v_i\} \) be dual bases in \( \mathfrak{n}_- \) and \( \mathfrak{n}_+ \) with respect to the pairing \(-\chi(\cdot, \cdot)\). Then the element \( B \) has the form

\[
B = 1 + h\pi(\sum_i u_i \otimes v_i) + O(h^2).
\]
Proof. By Proposition 3.2 the first two terms in the Taylor expansion of $F_\lambda$ at $\lambda = \infty$ are as follows,

$$F_\lambda = 1 + \lambda^{-1} \sum_i u_i \otimes v_i + \mathcal{O}(\lambda^{-2}).$$

Replacing $\lambda^{-1} \mapsto h$ and applying projection $\pi$ yields the result. \hfill \Box

Remark 4.13. The skew-symmetric part of the first order term in $h$ in the Taylor expansion of $B$ defines an invariant bi-vector on $M = G/H$. Its value at $eH \in M$ is given by $\sum_{i=1}^n u_i \wedge v_i$ which is exactly the Kirillov-Kostant-Souriau bi-vector on the coadjoint orbit.

Remark 4.14. By Remark 3.3 the elements $x_k \otimes y_l$ which occur with a factor $\lambda^{-n}$ in the element $F_\lambda$ have the property $d_k, d_l \leq n$. Hence, the bi-differential operators $B_n$ in the $*$-product $\pi(F_{h^{-1}})$ have the order $\leq n$ in each factor. Such $*$-products are called natural. In [GR] it is shown that a natural $*$-product induces a symplectic connection on the underlying manifold $M$. In the case of coadjoint orbits considered in this paper such a connection is defined by a $g_0$-invariant complement to to $g_0$ in $g$, $n_+ \oplus n_- \subset g$.

Example 4.15. Let $g = H_n$ be the Heisenberg algebra defined in Example 2.9, and let $\chi : c \mapsto w \in \mathbb{C}$ be a nonsingular character, $w \neq 0$. Then the matrix of the Shapovalov paring in each graded component $(U(n_-), k, U(n_+, k))$ is diagonal, with matrix elements

$$(q_1^{k_1} \cdots q_n^{k_n}, p_1^{k_1} \cdots p_n^{k_n})_{\lambda} = (-\lambda w)^k \prod_{i=1}^n k_i!,$$

where $k = k_1 + \cdots + k_n$. The corresponding inverse element $F_\lambda$ is given by

$$F_\lambda = \sum_{k_1, \ldots, k_n = 0}^{\infty} \frac{(-1)^k}{(\lambda w)^kk_1! \cdots k_n!} q_1^{k_1} \cdots q_n^{k_n} \otimes p_1^{k_1} \cdots p_n^{k_n}.$$

Using the product structure of $U(n_-) \otimes U(n_+)$ one can write the answer for $B$ in the following compact form,

$$B = \exp \left( -\frac{h}{w} \sum_{i=1}^n q_i \otimes p_i \right).$$

This gives a $*$-product on the coadjoint orbit $G/G_0 = \mathbb{R}^{2n}$ of the Heisenberg group acting on $g^*$. It is a ‘normal ordered’ version of the Moyal product [M].

Example 4.16. Let $g = sl(2, \mathbb{C})$ with generators $e, f, h$ and the Lie brackets $[e, f] = h, [h, e] = 2e, [h, f] = -2f$. Then $g_0 = Ch$ and $\chi(h) = z \in \mathbb{C}, z \neq 0$ defines a nonsingular character. The element $B$ associated to $sl(2, \mathbb{C})$ and $\chi$ is given by the formula

$$(6) \quad B = \sum_{n=1}^\infty h^n \left[ \frac{(-1)^n}{n!} \prod_1^n (z - (n-1)h) \right] f^n \otimes e^n.$$

Remark 4.17. By the theorem of Cahen, Gutt and Rawnsley [CGR], in case when $g$ is semisimple, there are no $*$-products on $g^*$ with the first order term given by the KKS Poisson bi-vector which restrict to the coadjoint orbits. This is illustrated by the above example: starting from the second graded component, the expression (6) for the $*$-product is singular at $z = 0$. 

\[ \]
Remark 4.18. Set $G = SU(2)$. Then the stabilizer of a nonsingular character $\chi \in \mathfrak{g}^*$ is isomorphic to $G_0 = U(1)$. The homogeneous space $M = G/G_0 = S^2$ is the underlying manifold for the $\ast$-product constructed above. In this case explicit formula for the $\ast$-product similar to (6) appeared before in physics literature in [P], [N] and [HNT].

Example 4.19. Let $\mathbf{Vir}$ be the Virasoro algebra defined in Example 2.10 and $\chi$ a nonsingular character. We will use the notation of 2.10 to give an explicit expression for the element $B$, corresponding to $\mathbf{Vir}$ and $\chi$, up to the second graded component. The character $\chi$ being nonsingular implies in particular that $\Delta \neq 0$ and $A := -32\Delta^3 - 4\Delta^2 c \neq 0$. Denote $B := 20\Delta^2 - 2\Delta c$, and set $D = A + hB$. Then

$$B = 1 - h \left[ \frac{1}{8\Delta} \right] L_{-1} \otimes L_1 + h \left[ \frac{8\Delta^2}{D} + h \frac{4\Delta}{D} \right] L_{-2} \otimes L_2 + h^2 \left[ \frac{6\Delta}{D} \right] L_{-2} \otimes L_2 -$$

$$- h^2 \left[ \frac{6\Delta}{D} \right] L_{-1} \otimes L_2 + h^2 \left[ \frac{A}{8\Delta} \right] L_{-2} \otimes L_2 + (U_{-3}) \otimes (U_{n_+})_{\geq 3}.$$
