Abstract
We study weighted total least squares problems on infinite dimensional spaces. We present some necessary and sufficient conditions for the regularized problem to have a solution. The existence of solution can also be assured for the regularized minimization problem with a constraint to special subsets. Furthermore, we show that a regularization in infinite dimensional total least squares problems is necessary, since in most cases the problem without regularization does not admit a solution.

Keywords: total least squares problems, Tikhonov regularization, inverse problems

1. Introduction

In the classic least squares problem [23, 27], to solve the inverse problem associated to a linear system \( Ax = b \), where \( A \) is a linear operator on a Hilbert space, the operator \( A \) is assumed to be known exactly and only \( b \) contains noise. However, this assumption may be unrealistic: sampling errors, human errors, modeling errors and instrument errors may imply inaccuracies of the operator \( A \).

In the finite dimensional case, to obtain approximate solutions of a linear system \( Ax = b \), with \( A \in \mathbb{R}^{m \times n} \) and \( b \in \mathbb{R}^m \), in which it is assumed that both the elements of \( A \) and \( b \) are known up to some noise, a widely used approach is to solve the so-called total least squares (TLS) problem. The usual formulation consists in finding (if there exists) a solution to the minimization problem

*Author to whom any correspondence should be addressed.
the existence of solution on infinite dimensional spaces and we show that it is a delicate matter. A valued decomposition is used, is not available. The main goal of this paper is to study TLS and set in infinite dimensional Hilbert spaces and the classic approach of [19], where singular decomposition of the augmented matrix \((A|b)\), is given.

In many occasions (for example in the case of integral equations), the problem is originally set in infinite dimensional Hilbert spaces and the classic approach of [19], where singular value decomposition is used, is not available. The main goal of this paper is to study TLS and related inverse problems on infinite dimensional spaces. In particular, we discuss extensively the existence of solution on infinite dimensional spaces and we show that it is a delicate matter.

Let us fix some notations: \(H, F\) are complex or real Hilbert spaces, \(L(H, F)\) is the set of bounded linear operators from \(H\) to \(F\) and \(L(H) := L(H, H)\).

Given \(A \in L(H, F)\) and \(b \in F\), in order to formulate the TLS problem in infinite dimensional Hilbert spaces, we introduce a positive (semidefinite) weight \(W \in L(F)\) such that \(W^{1/2} \in S_2\) (the Hilbert–Schmidt class). The problem is to find if there exists
\[
\min_{X \in L(H, F), x \in H} \|x - b\|^2_W + \|A - X\|^2_{L(W)}, \tag{1.1}
\]
where \(\|x\|^2_W = \|W^{1/2}x\|^2,\) for every \(x \in L(H, F)\) and \(\|z\|_W = \|W^{1/2}z\|,\) for every \(z \in F\), the seminorms associated to \(W\). We will refer to problem \(1.1\) as the weighted total least squares (WTLS) problem.

One typical application of the TLS problem is to ill-conditioned problems arising from integral equations. While these kind of application is of an infinite dimensional nature, the usual methods to solve the problem apply only to finite dimensional systems. Then, for such a problem, the TLS problem is usually solved for a discretization of the original equation and we cannot assure that this discretizations converge to the TLS associated to the original infinite dimensional problem. Moreover, it is not even clear whether this infinite dimensional TLS problem admits a solution. In fact, we will show that in most cases the TLS problem on infinite dimensional spaces does not admit a solution unless in the trivial case. We also exhibit a simple example where any finite dimensional approximation has solution but the original infinite dimensional problem does not (see example 3.6).

It is thus natural to consider a regularization on the TLS problem (even in the cases where the solution of the TLS problem exists regularizations are often considered in order to obtain a less contaminated solution, see for example \([4, 5, 18, 31]\)). We study the extension of the so-called Tikhonov regularization to infinite dimensional spaces. Given \(A, T \in L(H, F), b \in F\) and a positive (semidefinite) weight \(W \in L(F)\) such that \(W^{1/2} \in S_2\), the problem is to find if there exists
\[
\min_{X \in L(H, F), x \in H} (\|Tx\|^2 + \|x - b\|^2_W + \|A - X\|^2_{L(W)}). \tag{1.2}
\]
We will refer to problem \(1.2\) as the regularized weighted total least squares (RWTL) problem.

Recently, this problem has been studied on infinite dimensional Hilbert spaces, see \([6, 7]\). There, the authors stated general existence results under a hypothesis of weak to norm continuity of a certain bilinear application, which allows them to prove that the objective function is weakly lower semicontinuous. However, as we will see in section 5, this type of continuity does not hold in many reasonable cases. In fact, in general this application is not even weak to
weak continuous. We seek for conditions under which the continuity of the bilinear mapping may be assured (and hence the existence of solution of the RWTLS problem).

The paper is organized as follows. In section 2, we fix some notation and recall some concepts on ideals of operators. In the beginning of section 3, we prove that in most cases the non-regularized TLS problem does not have a solution on infinite dimensional spaces. Therefore, we focus our attention on the regularized problem (1.2) on infinite dimensional Hilbert spaces. We present necessary conditions for a pair \((A_0, x_0)\), to be a solution of the RWTLS problem. We observe that if the RWTLS problem has a solution \((A_0, x_0)\), then \(x_0\) is a solution of the classical smoothing problem [3, 9, 10, 13, 14] and the results obtained in [11] can be applied for giving necessary conditions for the existence of solution of problem (1.2). In section 3.3, we study the case where the regularization is given by a multiple of the identity operator, \(\rho I\). We apply there the Dinkelbach method to show that the RWTLS problem admits a solution when \(\rho \geq \rho^*\), where \(\rho^*\) is the infimum value of the RWTLS problem.

We show that \(\rho^*\) can be obtained via a semidefinite programming problem. In section 4, we give several examples that show that, on infinite dimensional spaces, the objective function we need to minimize to solve the RWTLS problem is not generally weakly lower semicontinuous. We also show that restricting the minimization problem to special subsets, the semicontinuity and hence the existence of solution may be assured.

2. Preliminaries

Throughout \(E, E_0, E_1, E_2\) denote complex or real Banach spaces, \(L(E_0, E_1)\) is the set of bounded linear operators from \(E_0\) to \(E_1\), \(L(E) := L(E, E)\). Denote \(E^*\) the dual space of \(E\). For any \(A \in L(E_0, E_1)\), its range and nullspace are denoted by \(R(A)\) and \(N(A)\), respectively.

We recall the concept of ideal of operators (see for example [15, 26]). We say that a class \(\mathcal{I}\) of bounded linear operators and a norm \(\| \cdot \|_\mathcal{I}\) form a normed ideal if for each set \(\mathcal{I}(E_0, E_1) := \mathcal{I} \cap L(E_0, E_1)\) one has that \(\mathcal{I}(E_0, E_1)\), \(\| \cdot \|_\mathcal{I}\) is a normed space containing all finite rank operators such that

(a) \(TXS \in \mathcal{I}(E, E_2)\) for every \(T \in L(E_1, E_2), S \in L(E, E_0)\) and \(X \in \mathcal{I}(E_0, E_1)\). Moreover,

\[
\|TXS\|_\mathcal{I} \leq \|T\|_{L(E_1, E_2)} \|X\|_{\mathcal{I}} \|S\|_{L(E, E_0)}.
\]

(b) If \(x' \in E_0^*\) and \(y \in E_1\) then \(\|x' (\cdot )y\|_\mathcal{I} = \|x'\|_{E_0^*} \|y\|_{E_1}\), where \((x' (\cdot ))y(x) := x'(x)y\) for \(x \in E_0\).

The symbols \(\mathcal{H}, \mathcal{E}, \mathcal{F}\) denote complex or real Hilbert spaces, \(L(\mathcal{H})^+\) is the cone of semidefinite positive operators and \(\leq\) stands for the order in \(L(\mathcal{H})\) induced by \(L(\mathcal{H})^+\), i.e., given \(A, B \in L(\mathcal{H})\), \(A \leq B\) if \(B - A \in L(\mathcal{H})^+\).

Given \(x \in \mathcal{H}\) and \(y \in \mathcal{F}\) the operator \((\cdot , x) y : \mathcal{H} \to \mathcal{F}\) is defined by \((\cdot , x) y = \langle h, x \rangle y\), for \(h \in \mathcal{H}\). Note that \((\cdot , x) y^* = (\cdot , x) y\) and that if \(W \in L(\mathcal{F}, \mathcal{E})\) then \(W (\cdot , x) y = \langle \cdot , x \rangle Wy\). Recall also that \(\text{tr}(\cdot , x) y = \langle x, y \rangle\), where \(\text{tr}\) denotes the trace of an operator.

Let \(T \in L(\mathcal{H}, \mathcal{F})\) be a compact operator. By \(\{\lambda_\ell(T)\}_{\ell \geq 1}\) we denote the eigenvalues of \(|T| := (TT^*)^{1/2} \in L(\mathcal{H})\), where each eigenvalue is repeated according to its multiplicity. We say that \(T\) belongs to the two-Schatten class \(S_2\), if \(\sum_{\ell \geq 1} \lambda_\ell(T)^2 < \infty\) and, the two-Schatten norm is given by \(\|T\|_2 := (\sum_{\ell \geq 1} \lambda_\ell(T)^2)^{1/2}\). Recall that \(S_2\) is a normed ideal of operators on Hilbert spaces.
3. Regularized weighted total least squares on Hilbert spaces

In order to motivate the study of RW TLS problems on Hilbert spaces, we begin this section by showing that in most cases the unregularized TLS problem on infinite dimensional spaces does not admit a solution unless in the trivial case. This proves that in this type of problems on infinite dimensional spaces, the assumption of solution is a delicate matter.

3.1. Weighted total least squares problems

The lack of solution of the TLS problem can be proven in a very general case. Let \((E_0, \| \cdot \|_{E_0}), (E_1, \| \cdot \|_{E_1})\) be a normed ideal of operators and let \((E_0, \| \cdot \|_{E_0}), (E_1, \| \cdot \|_{E_1})\) be normed spaces. Consider \(A \in L(E_0, E_1), W_0 \in I(E_1), W_1 \in L(E_1)\) and \(b \in E_1\), the problem is to determine if there exists

\[
\min_{x \in L(E_0, E_1)} \| W_0(A - X) \|_{F}^2 + \| W_1(Xx - b) \|_{E_1}^2.
\]

(3.1)

We will refer to problem (3.1) as the TLS problem.

We will say that problem (3.1) is trivial when the minimum in (3.1) is 0. Observe that problem (3.1) is trivial if and only if \(b \in R(A) + N(W_0) + N(W_1)\). In fact, if \(b = Ax_0 + z_0 + z_1\), with \(z_j \in N(W_j), j = 1, 2\), then taking \(X_0 = A + Z\), where \(R(Z) \subseteq N(W_0)\) and \(Zx_0 = z_0\), it follows that the pair \((X_0, x_0)\) is a solution of problem (3.1) and the minimum in (3.1) is 0.

Conversely, if the minimum in (3.1) is 0, then, there exists \(X_0 \in L(E_0, E_1)\) and \(x_0 \in E_0\) such that, \(W_0(A - X_0) = 0\) and \(W_1(X_0x_0 - b) = 0\). Then, \(X_0 = A + Z\), for some \(Z \in L(E_0, E_1)\) such that \(R(Z) \subseteq N(W_0)\) and \(b = X_0x_0 + z_1\) for some \(z_1 \in N(W_1)\). Hence, \(b = Ax_0 + Zx_0 + z_1 \in R(A) + N(W_0) + N(W_1)\).

In the next proposition, we suppose that \(b \notin R(A) + N(W_0) + N(W_1)\). Then the infinite dimensional extension of problem (3.1) never has solution:

**Proposition 3.1.** Let \(A \in L(E_0, E_1), W_0 \in I(E_1), W_1 \in L(E_1)\) and \(b \in E_1\) for some normed ideal of operators \(I\) such that \(W_0A\) is not bounded below. Then problem (3.1) does not have solution.

**Proof.** Since \(b \notin R(A) + N(W_0) + N(W_1)\). Then,

\[
\| W_0(A - X) \|_{F}^2 + \| W_1(Xx - b) \|_{E_1}^2 > 0,
\]

for any \((X, x) \in L(E_0, E_1) \times E_1\).

Since \(W_0A\) is not bounded below, for any \(\varepsilon > 0\), there is some \(x \in E_0\) such that \(\| x \| \geq 1\) and \(\| W_0Ax \|_{E_1} < \varepsilon\).

Take \(x' \in E_0^*\) such that \(x'(x) = \| x' \|_{E_0^*} = 1\) and define

\[
X_0 = A + \varepsilon x'(\varepsilon)(b - Ax/\varepsilon).
\]

Then \(X_0x/\varepsilon - b = Ax/\varepsilon - b + x'(\varepsilon)(b - Ax/\varepsilon) = 0\) and

\[
\| W_0(X_0 - A) \|_{F} = \| W_0 \varepsilon x'(\varepsilon)(b - Ax/\varepsilon) \|_{F} = \varepsilon \| x' \|_{E_0^*} \| W_0b - W_0Ax/\varepsilon \|_{E_1} \\ \\
= \varepsilon \| x' \|_{E_0^*} \| W_0b \|_{E_1} + \varepsilon^2 (\| W_0b \|_{E_1} + 1).\]

Therefore, \(\| W_0(A - X_0) \|_{F}^2 + \| W_1(X_0x/\varepsilon - b) \|_{E_1}^2 \leq 2\varepsilon^2 (\| W_0b \|_{E_1} + 1)^2\). Since this is true for arbitrarily small \(\varepsilon > 0\) we conclude that problem (3.1) does not have a solution.

**Remark 3.2.** We may also formulate the TLS problem imposing that the variable operator is in the normed ideal. In this case, no assumption on the weight is necessary in order to pose
the problem (in particular, the problem without weights is also possible). That is, given \( A \in \mathcal{I}(E_0, E_1) \), \( b \in E_1 \) and \( W_0, W_1 \in L(E_1) \), we may consider the problem of determining if there exists

\[
\min_{x \in \mathcal{I}(E_0, E_1) \backslash x \in E_0} \| W_0(A - X) \|^2 + \| W_1(Xx - b) \|^2_{E_1}.
\]

In this case, the same reasoning as in proposition 3.1 shows that if \( W_0A \) is not bounded below then this problem does not have solution. Note that if \( \mathcal{I} \) is an ideal of compact operators then \( W_0A \) is never bounded below.

In particular, let \( \mathcal{H} \) and \( \mathcal{F} \) be real or complex Hilbert spaces and, consider \( A \in L(\mathcal{H}, \mathcal{F}) \), \( b \in \mathcal{F} \) and \( W_0 = W_1 = W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \). The TLS problem in this case is to determine if there exists

\[
\min_{x \in L(\mathcal{H}, \mathcal{F}) \backslash x \in \mathcal{H}} \| A - X \|^2_{2,W} + \| Xx - b \|^2_W.
\]

We will refer to this problem as **WTLS problem in Hilbert spaces**. Observe that problem (WTLS) is trivial if and only if \( b \in R(A) + N(W) \). For the rest of this section, we suppose that \( b \notin R(A) + N(W) \).

**Corollary 3.3.** Let \( A \in L(\mathcal{H}, \mathcal{F}), b \in \mathcal{F} \) and \( W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \). Suppose that \( \dim(\mathcal{H}) = \infty \). Then problem (WTLS) does not have a solution.

**Proof.** The result follows from the above proposition because since \( W^{1/2} \) is a Hilbert–Schmidt (compact) operator, \( W^{1/2}A \) cannot be bounded below. \( \square \)

**Corollary 3.4.** Let \( A \in L(\mathcal{H}, \mathcal{F}), b \in \mathcal{F} \) and \( W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \). If \( A \) is not injective then problem (WTLS) does not have a solution.

### 3.2. Regularized weighted total least squares problems on Hilbert spaces

We know that the TLS problem on infinite dimensional Banach spaces does not have solution unless we are in a trivial case. Now we consider an associated problem, namely the Tikhonov regularized problem in infinite dimensional Hilbert spaces. We show some necessary and some sufficient conditions for the Tikhonov regularized problem to have solution and we present an example of existence.

Let \( \mathcal{H}, \mathcal{F}, \mathcal{E} \) be real or complex Hilbert spaces, \( A \in L(\mathcal{H}, \mathcal{F}), T \in L(\mathcal{H}, \mathcal{E}), b \in \mathcal{F} \) and \( W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \). Consider the following problem: finding the set of solutions of

\[
\min_{x \in L(\mathcal{H}, \mathcal{F}) \backslash x \in \mathcal{H}} \left( \| Tx \|^2 + \| A - X \|^2_{2,W} + \| Xx - b \|^2_W \right).
\]

We will refer to problem (RWTLS) as the **regularized weighted total least squares problem**.

In case \((A_0, x_0)\) is a solution of problem (RWTLS) and \( \delta = \| Tx_0 \| \), it is easy to see that \((A_0, x_0)\) is a solution of the WTLS problem with a quadratic constraint, i.e., \((A_0, x_0)\) is a solution of

\[
\min_{x \in L(\mathcal{H}, \mathcal{F}) \backslash x \in \mathcal{H}, \| Tx \| \leq \delta} \| A - X \|^2_{2,W} + \| Xx - b \|^2_W.
\]

Note that the minimum in (RWTLS) is 0 if and only if \( b \in A(N(T)) + N(W) \). We will say that in this case problem (RWTLS) is trivial.
As in the TLS problem, there are many cases where the (RWTLS) problem does not have a solution.

**Proposition 3.5.** Let $A \in L(\mathcal{H}, \mathcal{F})$, $T \in L(\mathcal{H}, \mathcal{E})$, $b \in \mathcal{F}$ and $W \in L(\mathcal{F})^+$ such that $W^{1/2} \in S_2$. If $T^*T + A^*WA$ is not bounded below [e.g. if $W^{1/2}A$ is not bounded below on $N(T)$] then either the problem (RWTLS) is trivial or it does not have a solution.

**Proof.** Since $T^*T + A^*WA$ is not bounded below, then it is not difficult to see that $(T^*T + A^*WA)^{1/2}$ is not bounded below. Therefore, given $\varepsilon > 0$ there exists $x \in \mathcal{H}$ such that

$$\|x\|_2 = 1 \text{ and}$$

$$\|(T^*T + A^*WA)^{1/2}x\| < \varepsilon^2.$$ 

Observe that $\|Tx\|^2 = \langle T^*Tx, x \rangle \leq \|(T^*T + A^*WA)x, x \rangle = \|(TT^* + A^*WA)^{1/2}x\|^2$. Similarly $\|W^{1/2}Ax\|^2 \leq \|(TT^* + A^*WA)^{1/2}x\|^2$.

Consider

$$X_0 = A + \langle \cdot, \varepsilon x \rangle(b - Ax/\varepsilon).$$

Then $X_0x/\varepsilon - b = Ax/\varepsilon + \|x\|^2(b - Ax/\varepsilon) - b = 0$ and

$$\|A - X_0\|_2^2 = \|\langle \cdot, \varepsilon x \rangle(b - Ax/\varepsilon)\|_2^2 = \|\langle \cdot, \varepsilon x \rangle W^{1/2}(b - Ax/\varepsilon)\|_2^2.$$

Hence

$$\|Tx/\varepsilon\|^2 + \|A - X_0\|_2^2 + \|X_0x/\varepsilon - b\|_W^2 = \|Tx/\varepsilon\|^2 + \|\langle \cdot, \varepsilon x \rangle W^{1/2}(b - Ax/\varepsilon)\|_2^2$$

$$= \frac{\|Tx\|^2}{\varepsilon^2} + \|\langle \cdot, \varepsilon x \rangle W^{1/2}(b - Ax/\varepsilon)\|_2^2$$

$$\leq \frac{\|Tx\|^2}{\varepsilon^2} + \varepsilon^2 \|x\|^2 \|W^{1/2}(b - Ax/\varepsilon)\|^2$$

$$\leq \frac{\|Tx\|^2}{\varepsilon^2} + \frac{\varepsilon^4}{\varepsilon^2} \left( \|W^{1/2}b\| + \|W^{1/2}Ax/\varepsilon\| \right)^2$$

$$\leq \frac{\varepsilon^4}{\varepsilon^2} + \frac{\varepsilon^2}{\varepsilon^2} \left( \|W^{1/2}b\| + \varepsilon^2 \right)^2$$

$$\leq \varepsilon^2 \left( 1 + \left( \|W^{1/2}b\| + \varepsilon^2 \right)^2 \right).$$

Since this holds for arbitrary $\varepsilon > 0$, either there exists $x \in N(T)$ such that $W^{1/2}Ax = W^{1/2}b$ or, the problem (RWTLS) does not have a solution.

The following simple example shows that we may have a (RWTLS) problem such that any finite dimensional restriction of the problem has a solution but the problem itself does not.

**Example 3.6.** Let $\mathcal{H} = \mathcal{F} = \mathcal{E}$, let $A$ be any operator, $b \neq 0$, $W^{1/2} \in S_2$ injective and $T$ any injective compact operator. Then by the above proposition, problem (RWTLS) does not have a solution.

On the other hand, suppose that $\mathcal{M}, \mathcal{N} \subset \mathcal{H}$ are any finite dimensional subspaces such that $A(\mathcal{M}) \subset \mathcal{N}$, and consider the truncated (RWTLS) problem, that is, the problem is to find the set of solutions of

$$\min_{X \in L(\mathcal{M}, \mathcal{N})} \|T|_{\mathcal{M}}x\|^2 + \|A|_{\mathcal{M}} - X\|_{2, W}^2 + \|Xx - b\|_W^2.$$

\[ \text{(2021) 045008 M Contino} \]
Since $T|_{\mathcal{M}}$ and $W^{1/2}|_{\mathcal{M}}$ are bounded, then $||T|_{\mathcal{M}}x||^2 + ||A|_{\mathcal{M}} - X||^2_{W^{1/2}} + ||X - b||_{W}^2$ is a coercive continuous function on the finite dimensional space $L(\mathcal{M}, \mathcal{N}) × \mathcal{M}$. Therefore, the truncated (RWTLS) has solution.

**Remark 3.7.** Suppose that $(A_0, x_0)$ is a solution of problem (RWTLS). Then $x_0$ is a solution of the smoothing (regularized least squares) problem:

$$\min_{x \in \mathcal{H}} \left( ||Tx||^2 + ||A_0x - b||^2_W \right). \tag{3.2}$$

On the other hand, by the last remark, since $(A_0, x_0)$ is asolutionof problem (RWTLS). Then, by the last remark, $A_0$ minimizes $F$.

We now study some necessary conditions for the existence of solution of problem (RWTLS). For doing that, the Fréchet derivative will be instrumental. Recall that, for a Banach space $(E, ||\cdot||)$ and an open set $\mathcal{U} \subseteq E$, a function $f : \mathcal{U} \to \mathbb{R}$ is said to be Fréchet differentiable at $x_0 \in \mathcal{U}$ if there exists $Df(x_0)$ a bounded linear functional such that

$$\lim_{Y \to 0} \frac{|f(X_0 + Y) - f(X_0) - Df(X_0)(Y)|}{||Y||} = 0.$$ 

If $f$ is Fréchet differentiable at every $X_0 \in \mathcal{U}$, $f$ is called Fréchet differentiable on $\mathcal{U}$ and the function $Df$ which assigns to every point $X_0 \in \mathcal{U}$ the derivative $Df(X_0)$, is called the Fréchet derivative of the function $f$. If, in addition, the derivative $Df$ is continuous, $f$ is said to be a class $C^1$ function, in symbols, $f \in C^1(\mathcal{U}, \mathbb{R})$.

**Proposition 3.8.** Given $x_0 \in \mathcal{H}$ and $W_1, W_2 \in L(\mathcal{F})^+$ such that $W_1^{1/2} \in S_2$. Let $K, k : L(\mathcal{H}, \mathcal{F}) \to \mathbb{R}$ be defined by $K(X) = ||W_1^{1/2}X||_2^2$ and $k(X) = \langle W_2Xx_0, Xx_0 \rangle$. Let $X, Y \in L(\mathcal{H}, \mathcal{F})$ then, $K$ and $k$ have Fréchet derivatives given by

$$DK(X)(Y) = 2 \text{ Re } \langle X^*W_1Y \rangle, \quad Dk(X)(Y) = 2 \text{ Re } \langle W_2Xx_0, Yx_0 \rangle.$$ 

See [[1], theorem 2.1], for a related result.

We now apply proposition 3.8 in order to give necessary conditions for the existence of solution of problem (RWTLS).

**Proposition 3.9.** Let $A \in L(\mathcal{H}, \mathcal{F})$, $T \in L(\mathcal{H}, \mathcal{E})$, $b \in \mathcal{F}$ and $W \in L(\mathcal{F})^+$ such that $W^{1/2} \in S_2$. Suppose that $(A_0, x_0)$ is a solution of problem (RWTLS) then $x_0$ is a solution of the normal equation

$$T^*Tx + A_0^*W(A_0x - b) = 0. \tag{3.3}$$

Moreover, $WA_0$ is the following rank one perturbation of $WA$

$$WA_0 = WA - \langle \cdot, x_0 \rangle W(A_0x_0 - b). \tag{3.4}$$

In particular, $A_0^*W(A_0 - A) = 0$.

**Proof.** Suppose that $(A_0, x_0)$ is a solution of problem (RWTLS). Then, by the last remark, $x_0$ is a solution of problem (3.2). Then, $x_0$ is a solution of the normal equation (3.3); see [[13], proof of theorem 3.2].

On the other hand, by the last remark, since $A_0$ minimizes $F$ and $F \in C^1(L(\mathcal{H}, \mathcal{F}), \mathbb{R})$, $A_0$ must be a critical point of $F$. By proposition 3.8, it is not difficult to see that
Thus, \( DF(A_0)(Y) = 0 \), for every \( Y \in L(H, F) \). So that

\[
0 = \text{Re} \left( \text{tr}((A_0 - A)^*WY) + \text{Re} \left( \langle x_0, Y^*W(A_0 - b) \rangle \right) \right) =
\]

\[
\text{Re} \left( \text{tr}(Y^*W(A_0 - A)) + \text{Re} \left( \text{tr}(\langle \cdot, x_0 \rangle Y^*W(A_0 - b)) \right) \right) =
\]

\[
\text{Re} \left( \text{tr}(Y^*W(A_0 - A)) + \text{Re} \left( \text{tr}(Y^*\langle \cdot, x_0 \rangle W(A_0 - b)) \right) \right) =
\]

\[
\text{Re} \left( \text{tr} \left( [W(A_0 - A) + \langle \cdot, x_0 \rangle W(A_0 - b)] \right) \right).
\]

Thus

\[
W(A_0 - A) + \langle \cdot, x_0 \rangle W(A_0 - b) = 0.
\]

\[\square\]

**Corollary 3.10.** Let \( A \in L(H, F), T \in L(H, E), b \in F \) and \( W \in L(F)^+ \) such that \( W^{1/2} \in S_2 \). Suppose that \( (A_0, x_0) \) is a solution of problem (RWTLs). Then

\[
(1 + \|x_0\|^2)T^*Tx_0 + A^*W(A_0 - b) = \frac{\|Ax_0 - b\|^2_W}{1 + \|x_0\|^2}x_0.
\]

Moreover,

\[
WA_0 = WA - \langle \cdot, x_0 \rangle W \frac{Ax_0 - b}{1 + \|x_0\|^2}.
\]

**Proof.** Note that by (3.4), \( W(A_0x_0 - b) = WAx_0 - \|x_0\|^2W(A_0x_0 - b) - Wb \) and thus,

\[
(1 + \|x_0\|^2)W(A_0x_0 - b) = W(Ax_0 - b).
\]

(3.5)

Therefore,

\[
\|Ax_0 - b\|^2_W = \langle W(Ax_0 - b), Ax_0 - b \rangle = (1 + \|x_0\|^2) \langle W(A_0x_0 - b), Ax_0 - b \rangle
\]

\[
= (1 + \|x_0\|^2)^2 \langle Ax_0 - b, W(A_0x_0 - b) \rangle = (1 + \|x_0\|^2)^2 \|Ax_0 - b\|_W^2,
\]

and consequently,

\[
A^*W(Ax_0 - b) = A^*W(A_0x_0 - b)(1 + \|x_0\|^2)
\]

\[
= (A^*W + \langle \cdot, W(A_0x_0 - b) \rangle x_0) (A_0x_0 - b)(1 + \|x_0\|^2)
\]

\[
= (A^*W(A_0x_0 - b) + \|A_0x_0 - b\|^2_W x_0) (1 + \|x_0\|^2)
\]

\[
= -(1 + \|x_0\|^2)T^*Tx_0 + \frac{\|Ax_0 - b\|^2_W}{1 + \|x_0\|^2}x_0,
\]

where we used (3.3) for the last equality. Finally, by (3.4) and (3.5), it follows that \( WA_0 = WA - \langle \cdot, x_0 \rangle W \frac{Ax_0 - b}{1 + \|x_0\|^2} \). \[\square\]
Inspired by the results in [4, 18] for finite dimensional spaces, we prove that the (RWTLS) problem has a solution \((A_0, x_0)\) if and only if, \(x_0\) minimizes some one-variable function.

**Theorem 3.11.** Let \(A \in L(H, F), T \in L(H, E), b \in F\) and \(W \in L(F)^+\) such that \(W^{1/2} \in S_2\). Let \(x \in H\) and consider \(F_x : L(H, F) \to \mathbb{R}\)

\[
F_x(X) = \|Tx\|^2 + \|A - X\|_W^2 + \|Xx - b\|_W^2.
\]

Then, for every \(x \in H\), there exists \(A_x \in L(H, F)\) which minimizes \(F_x\). Moreover

\[
F_x(A_x) = \frac{\|Ax - b\|_W^2}{1 + \|x\|^2} + \|Tx\|^2 =: G(x).
\]

**Proof.** Fixed \(x \in H\), proceeding as in the proof of proposition 3.9, if \(DF_x(X)(Y) = 0\) for every \(Y\). Then

\[
W(X - A) + \langle \cdot, x \rangle W(Xx - b) = 0.
\]

We claim that \(A_x\) verifies the first order conditions (3.6) if and only if \(F_x\) has a minimum in \(A_x\). In fact, suppose that \(A_x\) satisfies (3.6). Then

\[
F_x(X) = \|Tx\|^2 + \|A - A_x\|_W^2 + \|A_x - X\|_W^2
\]

\[
+ 2 \text{Re} \left( \text{tr}[(A_x - X)^*W(A - A_x)] \right) + \|A_x - X\|_W^2
\]

\[
+ \|Xx - A_xx\|_W^2 + 2 \text{Re} \langle (W(A_x - b), Xx - A_xx) \rangle
\]

\[
= F_x(A_x) + \|A_x - X\|_W^2 + \|Xx - A_xx\|_W^2,
\]

where the second equality follows because

\[
\text{tr}[(A_x - X)^*W(A - A_x)] = \text{tr}[(A_x - X)^*\langle \cdot, x \rangle W(A_x - b)]
\]

\[
= \langle W(A_x - b), (A_x - X)x \rangle
\]

\[
= -\langle W(A_x - b), Xx - A_xx \rangle.
\]

Therefore, \(F_x(X) \geq F_x(A_x)\) for every \(X \in L(H, F)\), so that \(A_x\) is a minimum of \(F_x\). The converse follows from the fact that \(F_x \in C^1(L(H, F), \mathbb{R})\). Moreover, it is not difficult to see that \(A_x = A + \frac{\langle A_x - X, x \rangle}{1 + \|x\|^2}(b - Ax)\) satisfies (3.6). Therefore, \(F_x\) has a minimum.

If \(A_x\) is a minimum of \(F_x\) then, \(A_x\) is a solution of equation (3.6) and proceeding as in corollary 3.10, it holds that \((1 + \|x\|^2)^2\|A_x - b\|_W^2 = \|Ax - b\|_W^2\) and \(\|A - A_x\|_W^2 = \|x\|^2\|A_x - b\|_W^2\). Consequently, the minimum of \(F_x\) is

\[
F_x(A_x) = \min_{X \in L(H, F)} F_x(X) = \|Tx\|^2 + \frac{\|Ax - b\|_W^2}{1 + \|x\|^2}.
\]

\[
= \|Tx\|^2 + \frac{\|Ax - b\|_W^2}{1 + \|x\|^2} = G(x).
\]

\(\square\)

**Corollary 3.12.** Let \(A \in L(H, F), T \in L(H, E), b \in F\) and \(W \in L(F)^+\) such that \(W^{1/2} \in S_2\). Then, there exists \(A_0\) such that \((A_0, x_0)\) is a solution of problem (RWTLS) if and only if \(x_0\) is a minimum of \(G\).
In this case, \( A_0 = A + \frac{\langle w_0 \rangle}{1 + |x_0|^2}(b - Ax_0) \).

**Proof.** If \((A_0, x_0)\) is a solution of problem \((\text{RWTLS})\) then, in one hand \( F_{x_0}(A_0) \leq F_x(X) \), for every \( x \in \mathcal{H}, X \in L(\mathcal{H}, \mathcal{F}) \) and, by theorem 3.11, \( F_{x_0} \) has a minimum in \( A_{x_0} \), so that
\[
G(x_0) = F_{x_0}(A_{x_0}) = F_{x_0}(A_0) \leq F_x(X),
\]
for every \( x \in \mathcal{H}, X \in L(\mathcal{H}, \mathcal{F}) \). By theorem 3.11, \( F_x \) has a minimum for every \( x \in \mathcal{H} \), then
\[
G(x_0) \leq \min_{X \in L(\mathcal{H}, \mathcal{F})} F_x(X) = G(x)
\]
for every \( x \in \mathcal{H} \).

Conversely, if \( x_0 \) is a minimum of \( G(x) \) then, by theorem 3.11,
\[
\min_{X \in L(\mathcal{H}, \mathcal{F})} F_{x_0}(X) = G(x_0) \leq G(x) = \min_{X \in L(\mathcal{H}, \mathcal{F})} F_x(X) \leq F_x(X),
\]
for every \( x \in \mathcal{H}, X \in L(\mathcal{H}, \mathcal{F}) \). As proved in theorem 3.11, \( A_0 := A + \frac{\langle w_0 \rangle}{1 + |x_0|^2}(b - Ax_0) \) is a minimum of \( F_{x_0} \) and,
\[
F_{x_0}(A_0) = \min_{X \in L(\mathcal{H}, \mathcal{F})} F_{x_0}(X) = G(x_0) \leq F_x(X),
\]
for every \( x \in \mathcal{H}, X \in L(\mathcal{H}, \mathcal{F}) \). Therefore, \((A_0, x_0)\) is a solution problem \((\text{RWTLS})\).

**Remark 3.13.** In finite dimensional Hilbert spaces, if \( T \) is invertible it is known that \( G \) has always a minimum because \( G \) is coercive, therefore \((\text{RWTLS})\) has a solution. See [[4], section 3].

Until now we have seen necessary conditions for the existence of solution of the \((\text{RWTLS})\), but the only cases in the infinite dimensional setting we presented do not have solution (proposition 3.5). We now show an example of a \((\text{RWTLS})\) that admits a solution, with \( A \) a diagonal operator on an infinite dimensional space.

**Example 3.14.** Let \( \mathcal{H} = \mathcal{F} = \mathcal{E} = \ell_2 \), the real Hilbert space of square summable sequences. Let \( A \) be the diagonal operator \( Ax = (a_n x_n)_n \), \( b = \sum_{j=1}^N b_j e_j \) a finite sequence, where \((e_j)_j\) is the canonical basis and \( W \) a diagonal weight operator, with weights \((w_j)_n \) in the diagonal. Let us see that problem \((\text{RWTLS})\) has a solution for \( T = \rho I \), for every \( \rho > 0 \).

Observe that, for any \( \alpha = \sum_{j=1}^N \alpha_j e_j \) and any \( s = \sum_{j>N} s_j e_j \),
\[
G \left( \sum_{j=1}^N \alpha_j e_j + \sum_{j>N} s_j e_j \right) = \sum_{j=1}^N w_j (\alpha_j - b_j)^2 + \sum_{j>N} w_j \alpha_j^2 + \rho^2 (\|\alpha\|^2 + \|s\|^2).
\]

Thus, for any \( \alpha, s \),
\[
G \left( \sum_{j=1}^N \alpha_j e_j + \sum_{j>N} s_j e_j \right) \geq \sum_{j=1}^N w_j (\alpha_j - b_j)^2 + \rho^2 (\|\alpha\|^2 + \|s\|^2)
\]
\[
:= h(\alpha, \|s\|).
\]
Identifying the span of the \( N \) first canonical vectors with \( \mathbb{R}^N \), the function \( h \) may be seen as a function from \( \mathbb{R}^{N+1} \) to \( \mathbb{R} \). Note that it suffices to prove that \( h \) has a minimum that is attained
at a point of the form \((\alpha^*, \|s^*\|) = (\hat{\alpha}, 0)\). Indeed, if we prove it then for any \(\alpha, s\) the following holds,

\[
G \left( \sum_{j=1}^{N} \alpha_j s_j + \sum_{j=N+1}^{N} \frac{w_j}{1 + \|s\|^2} s_j \right) \geq h(\alpha, \|s\|) \geq h(\hat{\alpha}, 0)
\]

\[
= \sum_{j=1}^{N} w_j (a \hat{\alpha}_j - b_j)^2 + \rho^2(\|\hat{\alpha}\|^2) = G(\hat{\alpha}).
\]

In other words, \(\hat{\alpha}\) would be a global minimum of \(G\).

Note also that \(h\) is a coercive everywhere differentiable function of \(N + 1\) variables. Then, its minimum must be attained at a critical point. Thus, it is sufficient to show that for any critical point \((\alpha, \|s\|)\), we have \(h(\alpha, \|s\|) \geq \min_{\alpha} h(\hat{\alpha}, 0)\).

Since,

\[
\frac{\partial h}{\partial \|s\|} = -\frac{\left(\sum_{j=1}^{N} w_j (a \alpha_j - b_j)^2\right) 2\|s\|}{(1 + \|\alpha\|^2 + \|s\|^2)^2} + 2\rho^2\|s\|,
\]

\[
\frac{\partial h}{\partial \alpha_j} = 0 \implies \text{either } s = 0 \text{ or }
\]

\[
\rho^2 = \frac{\left(\sum_{j=1}^{N} w_j (a \alpha_j - b_j)^2\right)}{(1 + \|\alpha\|^2 + \|s\|^2)^2}, \tag{3.7}
\]

If \(s = 0\), we are done because the critical point is of the form \((\hat{\alpha}, 0)\).

For the other case, since

\[
\frac{\partial h}{\partial \alpha_j} = \frac{2 w_j a_j (a \alpha_j - b_j) (1 + \|\alpha\|^2 + \|s\|^2) - 2 a_j \left(\sum_{j=1}^{N} w_j (a \alpha_j - b_j)^2\right)}{(1 + \|\alpha\|^2 + \|s\|^2)^2} + 2\rho^2 a_j,
\]

we have that \(\frac{\partial h}{\partial \alpha_j} = 0\) and equation (3.7) imply that \(\frac{w_j a_j (a \alpha_j - b_j)}{1 + \|\alpha\|^2 + \|s\|^2} = 0\).

Thus, if \(\{1, \ldots, N\} = C \cup D\) with \(w_i a_i = 0\) for \(i \in C\) and \(w_i a_i \neq 0\) for \(i \in D\), then \(\alpha_j = \frac{b_j}{a_j}\) for every \(j \in D\).

Suppose first that \(w_j a_j \neq 0\) for every \(j \leq N\), i.e. \(C = \emptyset\). Then \(\alpha_j = \frac{b_j}{a_j}\) for every \(j \leq N\). Thus, replacing this again in (3.7), we obtain \(\rho = 0\), which is a contradiction (and thus only the case \(s = 0\) is possible).

If \(C \neq \emptyset\), say \(k \in C\), let \((\alpha^*, \|s^*\|)\) be a critical point. Thus \(\alpha^* = \sum_{j \in C} a_j \alpha_j e_j + \sum_{j \in D} b_j e_j\), and let

\[
\hat{\alpha} := \left(\|s^*\|^2 + \sum_{j \in C} (\alpha_j^*)^2\right)^{1/2} e_k + \sum_{j \in D} b_j e_j.
\]

Then, since \(\|\hat{\alpha}\|_{2^{K+1}} = \|\alpha^*, \|s^*\||\|_{2^{K+1}}\), it easy to check that \(h(\hat{\alpha}, 0) = h(\alpha^*, \|s^*\|)\), which is what we wanted to prove.
3.2.1. Error bounds. In [22], error bounds for the accuracy of a regularized TLS problem were given, assuming the existence of solution of this problem. We are going to apply some ideas found on that work in order to estimate an error bound between the solution of some underlying (noise free) equation and a solution given by the RWTLS problem. Let $\mathcal{H}, \mathcal{F}, \mathcal{E}$ be real Hilbert spaces and consider the ill-posed problem

$$A_0 x = y_0$$ (3.8)

with $A_0 \in L(\mathcal{H}, \mathcal{F})$ injective with non-closed range and $y_0 \in R(A_0)$. Let $x_0 \in \mathcal{H}$ be the unique solution of (3.8).

As in [22], suppose that instead of the exact $y_0 \in R(A_0)$ we have noisy data $y_\delta \in \mathcal{F}$ such that \( \|y_0 - y_\delta\| \leq \delta \). Also, let $W \in L(\mathcal{F})^*$ such that $W^{1/2} \in S_2$ and suppose that instead of the exact operator $A_0 \in L(\mathcal{H}, \mathcal{F})$ we have some noisy operator $A_\delta \in L(\mathcal{H}, \mathcal{F})$ such that \( \|A_0 - A_\delta\|_{2, W} \leq h \). In this case, let $T \in L(\mathcal{H}, \mathcal{E})$ and consider the RWTLS problem

$$\min_{x \in L(\mathcal{H}, \mathcal{E}), x \in \mathcal{H}} (\|Tx\|^2 + \|A_\delta - X\|_{2, W}^2 + \|Xx - y_\delta\|_W^2).$$ (3.9)

We suppose here that problem (3.9) admits a solution $(\hat{X}, \hat{x})$. Suppose also that the exact solution $x_0$ of problem (3.8) satisfies that \( \|\hat{x}\|_W \leq \|x_0\|_W \) and $x_0$ satisfies a variant of the source condition:

$$Wx_0 = A_0^* Wv$$ (3.10)

for some $v \in \mathcal{K}$. If $\|Tx_0\| \leq \|Tx\|$ then we can prove the following bound for the error of the solution of the RWTLS problem:

$$\|x_0 - \hat{x}\|_W^2 \leq \|v\|_W \max\{1, \|\hat{x}\|\} \left(2 + 2\sqrt{2}\right) \left(\|W^{1/2}\|\delta + \hat{h}\right).$$ (3.11)

In fact, it is clear that

$$\|A_\delta - \hat{X}\|_{2, W}^2 + \|\hat{X}\hat{x} - y_\delta\|_W^2$$

$$\leq \left(\|Tx_0\|^2 - \|T\hat{x}\|^2\right) + \|A_\delta - A_0\|_{2, W}^2 + \|A_0 x_0 - y_\delta\|_W^2$$

$$\leq \|A_\delta - A_0\|_{2, W}^2 + \|y_0 - y_\delta\|_W^2 \leq h^2 + \|W^{1/2}\|^2 \delta^2.$$

Now, we are going to prove (3.11) using similar arguments as those found in [22, theorem 6.1]. Since $\|\hat{x}\|_W \leq \|x_0\|_W$, it follows that

$$\|x_0 - \hat{x}\|_W \leq 2 \left(Wx_0, x_0 - \hat{x}\right) = 2 \left(A_0^* Wv, x_0 - \hat{x}\right) = 2 \left(Wv, A_0 x_0 - A_0 \hat{x}\right)$$

$$\leq 2 \|v\|_W \|A_0 x_0 - A_0 \hat{x}\|_W.$$

By the triangle inequality, we have

$$\|A_0 x_0 - A_0 \hat{x}\|_W \leq \|A_0 x_0 - y_\delta\|_W + \|y_\delta - \hat{X}\hat{x}\|_W + \|\hat{X}\hat{x} - A_\delta \hat{x}\|_W + \|A_\delta \hat{x} - A_0 \hat{x}\|_W.$$

But,

$$\|A_0 x_0 - y_\delta\|_W + \|A_\delta \hat{x} - A_0 \hat{x}\|_W = \|y_0 - y_\delta\|_W + \|A_\delta \hat{x} - A_0 \hat{x}\|_W$$

$$\leq \|W^{1/2}\|\delta + \|W^{1/2}(A_\delta - A_0)\|\|\hat{x}\|$$

$$\leq \|W^{1/2}\|\delta + \|A_\delta - A_0\|_{2, W} \|\hat{x}\|$$

$$\leq \max\{1, \|\hat{x}\|\} \left(\|W^{1/2}\|\delta + h\right).$$
where we used that $\|S\| \leq \|S\|_2$ for any $S \in S_2$. Also, by the inequality $a + b \leq \sqrt{2(a^2 + b^2)}$, it follows that

$$\|y_\delta - \hat{X}\|_W + \|\hat{X} - A_h \hat{x}\|_W \leq \|y_\delta - \hat{X}\|_W + \|W^{1/2}(A_h - \hat{X})\|\|\hat{x}\|$$

$$\leq \|y_\delta - \hat{X}\|_W + \|A_h - \hat{X}\|_2 \|\hat{x}\|_W$$

$$\leq \max\{1, \|\hat{x}\|\} \sqrt{2(\|y_\delta - \hat{X}\|^2_W + \|A_h - \hat{X}\|^2_W)}$$

$$\leq \max\{1, \|\hat{x}\|\} \sqrt{2(\|W^{1/2}\|^2_2 \delta^2 + h^2)}$$

$$\leq \max\{1, \|\hat{x}\|\} \sqrt{2(\|W^{1/2}\| \delta + h)}.$$  

This proves (3.11).

### 3.3. The case $T$ is a multiple of the identity

In this subsection, we find some sufficient conditions for the existence of solution when the regularization operator $T$ is a multiple of the identity. Let $A \in L(H, F)$, $T \in L(H, E^r)$, $b \in F$ and $W \in L(F)^+$ such that $W^{1/2} \in S_2$, by corollary 3.12, to solve the (RWTLS) problem, is equivalent to minimizing the function $G$. We suppose in this section that $T = \rho^{1/2}I$ (a multiple of the identity), so that, the problem is to minimize

$$G(x) = \frac{\|Ax - b\|_W^2}{1 + \|x\|^2} + \rho \|x\|^2,$$

for a given constant $\rho > 0$. We will apply to $G$ the Dinkelbach method, see [[4], section 5.2] and [17].

Let us call $t^* \geq 0$ to the infimum of $G(x)$, varying $x \in H$. Then the infimum of the expression

$$\|Ax - b\|_W^2 + \rho \|x\|^4 + (\rho - t^*) \|x\|^2 - t^*,$$  

(3.12)

is 0. Moreover, $x_0$ minimizes $G$ if and only if $x_0$ minimizes (3.12) and in this case, the minimum of the expression in (3.12) equals 0.

Let us define

$$\phi(t) := \inf_x \left\{ \|Ax - b\|_W^2 + \rho \|x\|^4 + (\rho - t) \|x\|^2 - t \right\}.$$  

Then $\phi$ is a decreasing function and thus it has at most one zero. Moreover, since $\phi(t^*) = 0$ by definition, $t^*$ is the only root of $\phi$.

**Corollary 3.15.** If $\rho \geq t^*$ then problem (RWTLS) with $T = \rho^{1/2}I$ has a unique solution.

**Proof.** By the above comments, the infimum in (3.12) is 0. Moreover, if we have that $\rho \geq t^*$ then (3.12) is a strictly convex coercive function of $x$ and therefore it has a unique minimizer $x_0$. By the above comments, $x_0$ is the unique minimizer of $G$ and, by corollary 3.12, $x_0$ must be the unique solution of problem (RWTLS).
Remark 3.16. Suppose \( \rho \geq \| b \|_W^2 \) then problem (RWLS) with \( T = \rho^{1/2} I \) has a unique solution. Indeed, note that since \( G(0) = \| b \|_W^2 \), we have that \( t^* \) is always less than or equal to \( \| b \|_W^2 \).

3.3.1. How to find \( t^* \). In this subsection we give a characterization of \( t^* \) and as a corollary we present more sufficient conditions for the existence of solutions of problem (RWLS). In this subsection, we suppose that \( \mathcal{H} \) is a real Hilbert space.

The following lemma, which is a partial extension of [24, theorem 1] to infinite dimensional spaces will be a crucial tool for the results in this subsection. See [12].

**Lemma 3.17.** Let \( f(x) = \langle Sx, x \rangle + \langle x, a \rangle + s \), with \( S \in L(\mathcal{H}) \) nonnegative, \( a \in \mathcal{H}, s \in \mathbb{R} \), let \( g(x) = \| x \|^2 \) and let \( F : \mathbb{R}^2 \to \mathbb{R} \) defined as

\[
F(z) = \langle \Theta z, z \rangle + \langle z, v \rangle - t,
\]

where \( \Theta \) is a real symmetric nonnegative \( 2 \times 2 \) matrix, \( v = (v_1, v_2) \in \mathbb{R}^2 \) and \( t \in \mathbb{R} \). Then the following are equivalent:

(a) \( F(f(x), g(x)) \geq 0 \) for every \( x \in \mathcal{H} \).
(b) There exist \( \alpha, \beta \in \mathbb{R} \) such that for every \( x \in \mathcal{H} \) and every \( z = (z_1, z_2) \in \mathbb{R}^2 \),

\[
F(z) + \alpha(f(x) - z_1) + \beta(g(x) - z_2) \geq 0.
\]

Moreover, if \( S \) is not bounded below, \( \Theta = \begin{pmatrix} 0 & 0 \\ 0 & \rho \end{pmatrix} \) and \( v_1 > 0 \), then \( \alpha \) and \( \beta \) can be chosen nonnegative.

The following gives a characterization of the infimum \( t^* \). See [24] for a similar result on finite dimensional spaces.

**Proposition 3.18.** Let \( A \in L(\mathcal{H}, \mathcal{F}), b \in \mathcal{F}, W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \) and \( \rho > 0 \). The infimum \( t^* \) of \( G \) is the maximum of all \( t \in \mathbb{R} \) such that there exist \( \alpha, \beta \in \mathbb{R} \) such that \( C \in L(\mathcal{H} \times \mathbb{R}^3) \) is a nonnegative operator, where \( C \) is the operator defined as

\[
C := \begin{pmatrix}
\alpha A^* W A + \beta I & 0 & 0 & \frac{-\alpha A^* W b}{1 - \alpha} \\
0 & 0 & 0 & \frac{\rho - t - \beta}{2} \\
0 & 0 & 0 & \frac{\rho - t - \beta}{2} \\
\frac{1 - \alpha}{2} & \frac{\rho - t - \beta}{2} & \alpha \| b \|_W^2 - t & 0
\end{pmatrix}.
\]

**Proof.** Let us denote \( f(x) = \| Ax - b \|_W^2 \) and \( g(x) = \| x \|^2 \). Then note that

\[
t^* = \max_{t \in \mathbb{R}} \left\{ t : f(x) + \rho g(x)^2 + (\rho - t) g(x) - t \geq 0, \quad \forall x \in \mathcal{H} \right\}
\]

\[
= \max_{t, \alpha, \beta \in \mathbb{R}} \left\{ t : 0 \geq \alpha \left( z_1 + \rho z_2^2 + (\rho - t) z_2 - t + \alpha f(x) - z_1 \right) + \beta \left( g(x) - z_2 \right) \\
\quad \geq 0, \quad \forall x \in \mathcal{H}, z_1, z_2 \in \mathbb{R} \right\},
\]

where the first equality holds by the comments at the beginning of the section and the last equality holds from the above lemma applied to \( f(x) = \| Ax - b \|_W^2 = \langle A^* W A x, x \rangle - 2 \langle x, A^* W b \rangle + \langle W b, b \rangle \) and \( F(z) = \rho z_2^2 + z_1 + (\rho - t) z_2 - t \). Note that, by the above lemma, \( \alpha \) and \( \beta \) can be chosen nonnegative.
Let \( x \in \mathcal{H}, z_1, z_2 \in \mathbb{R}, y = (x, z_1, z_2, 1) \in \mathcal{H} \times \mathbb{R}^3 \), then
\[
\langle Cy, y \rangle = \langle (\alpha A^*W + \beta I) x, x \rangle - 2\alpha \langle A^*Wb, x \rangle \\
+ (1 - \alpha) z_1 + \rho \sigma^2 + (\rho - t - \beta) z_2 - \alpha \|b\|^2_W - t \\
= z_1 + \rho \sigma^2 + (\rho - t) z_2 - t + \alpha \left( \|Ax - b\|^2_W - z_1 \right) + \beta \left( \|x\|^2 - z_2 \right).
\]
Therefore \( \langle Cy, y \rangle \geq 0 \) for every \( y = (x, z_1, z_2, 1) \in \mathcal{H} \times \mathbb{R}^3 \) if and only if \( z_1 + \rho \sigma^2 + (\rho - t) z_2 - t + \alpha \left( f(x) - z_1 \right) + \beta \left( g(x) - z_2 \right) \geq 0 \); for every \( x \in \mathcal{H}, z_1, z_2 \in \mathbb{R} \).

Finally, note that \( \langle C(x, z_1, z_2, 0), (x, z_1, z_2, 0) \rangle = \alpha \|Ax\|^2_W + \beta \|x\|^2 + \rho \sigma^2 \) is nonnegative because \( \alpha \) and \( \beta \) can be chosen nonnegative. \( \square \)

Let \( A \in L(\mathcal{H}, \mathcal{F}), b \in \mathcal{F}, W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \) and \( \rho > 0 \). The regularized least squares problem
\[
\min_{x \in \mathcal{H}} \|Ax - b\|^2_W + \rho \|x\|^2 W, (3.13)
\]
always has a solution, because the objective function is convex and coercive. Let \( a^* \) be the minimum of \( (3.13) \).

**Corollary 3.19.** Suppose that \( a^* \leq \rho \). Then problem (RWTLS) with \( T = \rho^{1/2}I \) has a unique solution.

**Proof.** It suffices to show that if we take any \( t > \rho \) then for every \( \alpha, \beta \in \mathbb{R} \), the matrix \( C \) from proposition 3.18 is not nonnegative. Indeed, in this case by proposition 3.18, \( t^* \leq \rho \) and by corollary 3.15, the (RWTLS) problem has a unique solution.

Let \( y = (x, z_1, z_2, 1) \in \mathcal{H} \times \mathbb{R}^3 \), then
\[
\langle Cy, y \rangle = (1 - \alpha) z_1 + \rho \sigma^2 + (\rho - t - \beta) z_2 - t + \alpha \|Ax - b\|^2_W + \beta \|x\|^2.
\]
Note that if \( \alpha \neq 1 \) then we can always choose \( z_1 \) so that \( \langle Cy, y \rangle < 0 \). Suppose \( \alpha = 1 \). Then
\[
\langle Cy, y \rangle = \rho \sigma^2 + (\rho - t - \beta) z_2 - t + \|Ax - b\|^2_W + \beta \|x\|^2.
\]
Taking \( z_2 = -\frac{\rho(t - \beta)}{2\rho} \) then \( \langle Cy, y \rangle = \|Ax - b\|^2_W + \beta \|x\|^2 - \frac{\rho(t - \beta)^2}{4\rho} - t \). Maximizing \( \beta \),
\[
\langle Cy, y \rangle \leq \|Ax - b\|^2_W + (\rho - t) \|x\|^2 + \rho \|x\|^4 - t.
\]
Let \( \tilde{x} \in \mathcal{H} \) such that \( a^* = \|A\tilde{x} - b\|^2_W + \rho \|\tilde{x}\|^4 \). Since \( a^* \leq \rho \), for \( y = (\tilde{x}, z_1, -\frac{\rho(t - \beta)}{2\rho}, 1) \) we have
\[
\langle Cy, y \rangle \leq \|A\tilde{x} - b\|^2_W + (\rho - t) \|\tilde{x}\|^2 + \rho \|\tilde{x}\|^4 - t \leq (\rho - t) \|\tilde{x}\|^2 + (\rho - t) < 0.
\]
Therefore \( C \) is not nonnegative. \( \square \)

4. **The restricted regularized total least squares problem**

Let \( A \in L(\mathcal{H}, \mathcal{F}), T \in L(\mathcal{H}, \mathcal{E}), b \in \mathcal{F} \) and \( W \in L(\mathcal{F})^+ \) such that \( W^{1/2} \in S_2 \) and consider problem (RWTLS). Suppose that the regularization operator \( T \) is invertible. Then, in the finite dimensional case, the existence of solution of problem (RWTLS) is guaranteed by the fact that the objective function \( \|T x\|^2 W + \|A - X\|^2_W + \|X x - b\|^2_W \) is continuous and coercive on
\(L(H, F) \times H\), see e.g. [32]. A natural approach, in the infinite dimensional case would be to minimize coercive and weakly continuous (or at least weakly lower-semicontinuous) functions.

Since the norm is weakly lower-semicontinuous on any normed space, the first two terms in the objective function of the (RWTLS) problem are weakly lower-semicontinuous. Note that, if the mapping \((X, x) \mapsto Xx\) is (jointly) weakly continuous on bounded sets, then the third term of the objective function \(\|Xx - b\|_W\) is also weakly lower-semicontinuous.

In [6], a regularized TLS problem is studied on infinite dimensional Hilbert spaces. There an existence theorem is proved but their proof assumes a crucial property, which as we will see, is not satisfied in many reasonable cases. Their results follows from an assumption (assumption (A1) in [6]) which translates to the fact that, for example the bilinear mapping defined as

\[
B : S_2 \times H \rightarrow H,
\]

\[
(X, x) \mapsto Xx,
\]
is weak-to-norm continuous. But, this is not true: any orthonormal basis \((e_n)\) is weakly null (weak convergent to 0) in \(H\) and if \(X_n = \langle \cdot, e_n \rangle e_1\) (a rank 1 operator defined on \(H\)) then \((X_n)\) is also weakly null in \(S_2\); indeed if \(K \in S_2\) then \(\langle X_n, K \rangle = \langle \langle \cdot, e_n \rangle e_1 K^* \rangle = \langle K^* e_1, e_n \rangle \rightarrow 0\). But \(X_n e_1 = e_1\) for every \(n\), and thus \((X_n e_n)\) does not converge to zero in any topology. Therefore \(B\) is not weak-to-weak continuous. The same example shows that the function \((X, x) \mapsto \|Xx\|^2\) is not weakly lower-semicontinuous. Moreover, since \((X_n)\) also converges to 0 in the strong operator topology (SOT), \(B\) is also not SOT \(\times\) weak to weak continuous.

In order to assure existence of solution we may restrict either the set of operators or the set of vectors to smaller sets which have some kind of compactness. The aim of this section is to show that this is a delicate problem. We present a restricted regularized TLS problem in a general setting and show some cases in which we can assure the continuity of the bilinear mapping and hence the existence of solution. In the final subsection we show some very natural examples in which the bilinear mapping fails to be continuous.

### 4.1. Restricted regularized total least squares problem

The continuity of the bilinear mapping can be used to prove existence of a regularized TLS problem when restricted to suitable sets.

Let \(E_0, E_1, E_2\) be infinite dimensional Banach spaces, \(\mathcal{I} \subset L(E_0, E_1)\) be any normed ideal of operators and \(C \subset \mathcal{I}\) and \(D \subset E_0\) closed convex subsets.

Given \(A \in C \subset \mathcal{I}, T \in L(E_0, E_2)\) and \(b \in E_1\), we consider the following restricted regularized total least squares problem: find the set of solutions of

\[
\min_{X \in C \subset \mathcal{I}, x \in D \subset E_0} f(||Tx||_{E_2}, ||A - X||_{\mathcal{I}}, ||Xx - b||_{E_1})
\]

(RRTLS)

with \(f : \mathbb{R}^3_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}\) is any continuous, increasing and coercive function. For example, if \(f(t_0, t_1, t_2) = t_0^2 + t_1^2 + t_2^2\), then the function we should minimize is the same as in the previous section.

The most simple situation is when one of the subsets, \(C\) or \(D\) is norm compact:

**Proposition 4.1.** Suppose that \(T\) is bounded below and that either:

(a) \(C\) is compact, \(D = E_0\) with \(E_0\) reflexive.
(b) \(C = \mathcal{I}\) is a reflexive Banach space of operators and \(D\) is compact.
(c) \(C = \mathcal{I} = L(E_0, E_1)\) with \(E_1\) is reflexive and \(D\) is compact.

Then the (RRTLS) problem admits solution.
**Proof.** Let \( g(X, x) := f(\|Tx\|_{E_2}, \|A - X\|_I, \|Xx - b\|_{E_1}) \) and let \( B : \mathcal{I} \times E_0 \to E_1, B(X, x) = Xx \). Since \( f \) is coercive and \( T \) is bounded below, \( g \) is also coercive. Thus we may restrict the minimization problem to \( D \) and \( \overline{C} \), the intersection of \( D \) and \( C \) with some closed balls, respectively.

(a) The function \( (X, x) \mapsto Xx \) is continuous from \((\mathcal{C}, \| \cdot \|_I) \times (\overline{D}, w) \) to \((E_1, w)\). In fact, let \( y' \in E_1 \), let \((X_n)_n \subset \mathcal{C} \) be a norm convergent sequence to \( X \) and \((y'_n)_n \subset \overline{D} \) be a weak convergent net to \( y \). Then

\[
|y'(B(X_n, y'_n) - B(X, y))| \leq |y'(B(X_n - X, y'_n))| + |y'(B(X, y'_n) - B(X, y))|.
\]

The first term tends to zero because \( X_n \xrightarrow{\| \cdot \|_E} X \), bounded \( B \), and \( B \) is norm bounded. The second term approaches to zero because \( y'(B(X, \cdot)) \) is a continuous linear functional on \( E_0 \) and \( y'_n \xrightarrow{\text{w}} y \).

Thus, since the norm is a weakly-lower semicontinuous function, the composition \((X, x) \mapsto \|Xx - b\|_{E_1} \) is weakly-lower semicontinuous. Similarly, the function \( x \mapsto \|Tx\|_{E_2} \) is weakly-lower semicontinuous because \( T \) is weak to weak continuous and \( X \mapsto \|A - X\|_I \) is continuous. Thus \( g \) is weakly-lower semicontinuous on \((\mathcal{C}, \| \cdot \|_I) \times (\overline{D}, w)\), see \([25], \text{lemma 1.7}\) Finally, since \( E_0 \) is reflexive, \((C, \| \cdot \|_I) \times (\overline{D}, w)\) is compact and therefore \( g \) attains its minimum.

(b) The proof is similar, using that \((X, x) \mapsto Xx \) is continuous from \((\mathcal{C}, \| \cdot \|_I) \times (\overline{D}, \| \cdot \|_{E_2}) \) to \((E_1, w)\) and the compactness of \((\mathcal{C}, \| \cdot \|_I) \times (\overline{D}, \| \cdot \|_{E_2})\).

(c) The proof is the similar, proving the continuity of \((X, x) \mapsto Xx \) from \((\mathcal{C}, \text{WOT}) \times (\overline{D}, \| \cdot \|_{E_2}) \) to \((E_1, w)\). We must also use the fact that the closed unit ball of \( L(E_0, E_1) \) is WOT-compact when \( E_1 \) is reflexive.

Whenever \( \mathcal{I} = L(E_0, E_1) \), the following result allows us to prove the existence of solution of problem (RRTLS) when we ask \( C \) a condition which is weaker than compactness, namely weak equicontinuity.

The following definition was given in \([28]\):

**Definition 4.2.** A subset \( C \subset L(E_0, E_1) \) is said to be weakly \( w_0 \)-equicompact if for every weakly null sequence \((y_n)_n \subset E_0\) there exists a subsequence \((y_n)_n \subset E_0\) such that \((Xy_n)_n \subset E_0\) converges weakly uniformly for \( X \in C \) to 0.

**Proposition 4.3.** Suppose that \( T \) is bounded below and that \( C \subset L(E_0, E_1) \) is a closed and convex set which is weakly \( w_0 \)-equicompact set of operators and that \( D = E_0 \) is a reflexive Banach space.

Then the (RRTLS) problem admits solution.

**Proof.** We first observe that in this case the bilinear mapping \( B \) is \((C, \text{WOT}) \times (D, w) \) to \((E_1, w)\) continuous. This is a direct consequence of \([28], \text{lemma 2.6}\), which tells us that \( S(x_n - x) \xrightarrow{\text{w}} 0 \) uniformly for \( S \in C \), for any \( x_n \xrightarrow{\text{w}} x \).

Now, if \( g(X, x) := f(\|Tx\|_{E_2}, \|A - X\|, \|Xx - b\|_{E_1}) \), then \( g \) is coercive. Thus we may restrict the minimization problem to \( C \times \overline{D} \), where \( \overline{D} \) is the intersection of \( D \) with some closed ball. Also, since the operator norm is WOT lower semicontinuous, we may proceed as in (1) of proposition 4.1 to show that \( g \) is lower semicontinuous on \((C, \text{WOT}) \times (\overline{D}, w)\). Since \( C \) is closed and convex, it is WOT-compact. Therefore, \( g \) attains its minimum on \( C \times \overline{D} \).

**Remark 4.4.** Note that the conclusion of propositions 4.1 and 4.3 remain true for arbitrary \( T \) if we suppose additionally that \( D \) is bounded. In particular, this gives us existence results for the restricted TLS problem without regularization.
We present now an example showing that the above result can be applied to assure the existence of solution of problem \((RRTLS)\) on sets of triangular operators. This example is similar to example 3.14, here \(b\) is allowed to be any vector in \(\ell_2\), but we must restrict to a proper subsets of operators.

**Example 4.5.** Let \(H = F = E = \ell_2, A \in L(\ell_2), b \in \ell_2, T \in L(\ell_2)\) bounded below. We show that \((RRTLS)\) has solution when we minimize on a set \(C_N\) of operators which contains all operators with lower triangular matrix representations; given \(N \geq 0\) let

\[
C_N = \{ X \in L(\ell_2) : \langle X e_i, e_j \rangle = 0 \quad \text{for} \quad i < j + N \}.
\]

Since \(g(X, x) := f(\|Tx\|_2, \|A - X\|, \|X - b\|_2)\) is coercive, we may restrict \(x\) and \(X\) to some closed balls. Thus, by proposition 4.3, it suffices to see that for \(r > 0\), \(rE_2 \cap C_N\) is a weakly \(w_{02}\)-equicompact set of operators. By [[29], corollary 2.3] this can be proved if we show that for each \(y \in \ell_2\), the sets \((rE_2 \cap C_N)y := \{ X^*y : X \in C_N, \|X\| \leq r \}\) are relatively compact sets in \(\ell_2\).

This is easily seen applying a classical result of Fréchet (see e.g. [[20], theorem 4]), according to which it suffices to see that given \(\varepsilon > 0\), there is some \(n\) such that for every \(X^* \in rE_2 \cap C_N\),

\[
\sum_{j > n} |\langle X^*y, e_j \rangle|^2 < \varepsilon.
\]

Let \(n\) be such that that \(\sum_{j > n - N} y_j^2 < \varepsilon / r^2\) and denote by \(y^\#_{n-N}\) the tail of \(y\) so that \(\|y^\#_{n-N}\|^2 < \varepsilon / r^2\). Let \(X \in rE_2 \cap C_N\), then

\[
\sum_{j > n} |\langle X^*y, e_j \rangle|^2 = \sum_{j > n} \left( \sum_{l > n - N} y_l \langle X^*e_l, e_j \rangle \right)^2
= \sum_{j > n} |\langle X^*y^\#_{n-N}, e_j \rangle|^2 \leq \|X^*\|^2 \|y^\#_{n-N}\|^2 < \varepsilon.
\]

For \(I = K(E_0, E_1)\), the space of compact operators, we can assure the existence of solution of the \((RRTLS)\) problem restricted to weakly compact sets whenever the space \(E_0\) has the Dunford–Pettis property. To achieve this we prove that the bilinear mapping in this case is weakly sequentially continuous. We will actually see in the next proposition that the Dunford–Pettis property characterizes this continuity for the bilinear mapping.

Recall that a Banach space \(E_0\) is said to have the *Dunford–Pettis property* if for each Banach space \(E_1\), every weakly compact linear operator \(S : E_0 \to E_1\) is completely continuous, i.e., \(S\) takes weakly compact sets in \(E_0\) onto norm compact sets in \(E_1\). An important characterization for \(E_0\) to have the Dunford–Pettis property is that for any weakly null sequences \((x_n)_n\) of \(E_0\) and \((y_n)_n\) of the dual space \(E_0^*\), the sequence \(y_n^*(x_n)\) converges to 0. See [[16], theorem 1].

Some examples of spaces with the Dunford–Pettis property are \(C(K)\) spaces, \(L^1(\mu)\)-spaces and spaces whose duals are either \(C(K)\) or \(L^1(\mu)\)-spaces, spaces of analytic functions like \(H^\infty\) or the disc algebra or the spaces of smooth functions on the \(n\)-dimensional torus \(C^a(T^n)\). We refer the reader to [8, 16].

**Proposition 4.6.** Let \(B : K(E_0, E_1) \times E_0 \to E_1\) be the bilinear mapping,

\[
B(X, y) = Xy.
\]

Then \(B\) is weakly sequentially continuous (that is, \(B\) sends weakly convergent sequences in \(E_0\) and \(K(E_0, E_1)\) to a weakly convergent sequence in \(E_1\)) if and only if \(E_0\) is a Banach space with the Dunford–Pettis property.
In this case, if $C \subset K(E_0, E_1)$ and $D \subset E_0$ are a weakly-compact sets then the (RRTLS) problem admits solution.

**Proof.** Suppose first that $E_0$ lacks the Dunford–Pettis property. Then, there are weakly null sequences $(y_n)_n \subset E_0$ and $(y'_n)_n \subset E_2$ such that $y'_n(y_n) \to 1$. Take any nonzero vector $y_1 \in E_1$ and define $X_n(y) = y'_n(y) y_1$. Thus, $z(X'_n(y')) = z(y'_n) y'(y_1) \to 0$ for every $z \in E_0^*$ and every $y' \in E_1^*$. Thus $X_n \rightharpoonup w^*$, By [[21], corollary 3], $(T_n)_n$ converges weakly to 0.

On the other hand, $B(X_n, y_n) = y'_n(y_n)y_1 \to y_1 \neq B(w - \lim X_n, w - \lim y_n) = B(0, 0) = 0$. Therefore, $B$ is not weakly sequentially continuous.

Conversely, suppose now that $E_0$ has the Dunford–Pettis property. Since $D \subset E_0$ is weakly compact then for each sequence $(y_n)_n \subset D$, $y'_n(y_n) \to 0$ for every weak null sequence $(y'_n)_n$.

Let $y_n \rightharpoonup y$, $X_n \rightharpoonup X$ and take $y' \in E_1^*$. Since weak convergence implies WOT* convergence, it is not difficult to see that $(y' \circ (X_n - X))_n$ is a weak null sequence in $E_0^*$, and thus

$$y' \circ (X_n - X)(y_n) \to 0.$$ 

Therefore

$$y'(B(X_n, y_n) - B(X, y)) = y'(B(X_n, y_n) - B(X, y_n)) + y'(B(X, y_n) - B(X, y)) = y' \circ (X_n - X)(y_n) + (y' \circ X)(y_n - y) \to 0.$$ 

Hence, $B$ is weakly sequentially continuous.

In this case, if $C \subset K(E_0, E_1)$ and $D \subset E_0$ are weakly-compact sets then the (RRTLS) problem admits solution. In fact, since the norm is a weakly-lower semicontinuous function, the composition $(X, x) \mapsto \|X - b\|_{E_1}$ is sequentially weakly-lower semicontinuous. Then, if $g(X, x) = f(\|Tx\|_{E_2}, \|A - X\|, \|X - b\|_{E_1})$, then $g$ is sequentially weakly-lower semicontinuous on $(C, w) \times (D, w)$, see [[25], lemma 1.7]. Finally, since $C$ and $D$ are weakly compact, by the Eberlein–Smulian theorem, they are sequentially weakly compact and therefore $g$ attains its minimum.

In the previous theorem we can drop the hypothesis that $X \in K(E_0, E_1)$ to prove that $B$ is weakly sequentially continuous. That is, consider $B : L(E_0, E_1) \times E_0 \rightharpoonup E_1$ the bilinear mapping,

$$B(X, y) = X y,$$

and $E_0$ a Banach space with the Dunford–Pettis property. Then, for any weakly-compact sets $C \subset L(E_0, E_1)$ and $D \subset E_0$, the (RRTLS) problem admits solution. Note also that since $T$ need not to be bounded below here, we can also conclude the existence of solution for the restricted TLS problem without regularization.

### 4.2. A variant to the regularized total least squares problem

We now briefly present a modification to the regularized TLS problem which gives rise to a weak continuous bilinear mapping.

Let $E_0, E_1, E_2, E_3$ be infinite dimensional Banach spaces, $I \subset L(E_1, E_2)$ be any normed ideal of operators.

Given $A \in I$, $T \in L(E_0, E_1)$, $K \in K(E_0, E_1)$ a compact operator and $b \in E_2$, we may consider the following problem: find the set of solutions of

$$\min_{X \in I, \; x \in E_0} f(\|Tx\|_{E_2}, \|A - X\|_{I}, \|XKx - b\|_{E_2})$$

with $f : \mathbb{R}^3_{\geq 0} \to \mathbb{R}_{\geq 0}$ is any continuous, increasing and coercive function.

The fact that $K$ is a fixed compact operator implies that $(KX)_I$ is norm convergent for any weakly convergent net $(x_\lambda)_\lambda$. Thus the bilinear mapping $(X, x) \mapsto XKx$ is weak-to-weak
continuous. Therefore, proceeding as in proposition 4.1 (2) and (3), it can be shown that the
above problem admits solution whenever \( \mathcal{I} \) and \( E_0 \) are reflexive or \( \mathcal{I} = L(E_1, E_2) \) and \( E_0 \) and
\( E_2 \) are reflexive.

A typical example where this result can be applied is when \( E_0 \) is a Sobolev space, \( E_1 \)
is an appropriate \( L^p \) space and \( K \) is the inclusion \( E_0 \hookrightarrow E_1 \). In this case, the well-known
Rellich–Kondrachov theorem assures the compactness of the inclusion.

4.3. Counterexamples to the weak continuity of the bilinear mapping

Restricting the (RWTLs) problem to different types of operators we would obtain slightly
different bilinear mappings. The following examples show that these bilinear mappings are
usually not weak-to-weak continuous.

**Example 4.7.** On the Hilbert space \( L^2(\Omega) \), consider an integral Hilbert–Schmidt operator,

\[
A_0 f(s) = \int_{\Omega} k_0(s, t) f(t) dt,
\]

where \( k_0 \in L^2(\Omega^2) \). Recall that \( \|A_0\|_2 = \|k_0\|_{L^2(\Omega^2)} \). We show that the bilinear mapping

\[
B : L^2(\Omega^2) \times L^2(\Omega) \to L^2(\Omega)(k, f) \mapsto B(k, f)(s) = \int_{\Omega} k(s, t) f(t) dt,
\]

is not weak-to-norm continuous. Let \((e_n)\) be any orthonormal basis of \( L^2(\Omega) \) (thus a weakly
null sequence) and take \( g \in L^2(\Omega) \). Define \( k_n(s, t) = g(s)e_n(t) \). It is easy to see that \((k_n)\) is
weakly null in \( L^2(\Omega^2) \).

But

\[
B(k_n, e_n)(s) = g(s) \int_{\Omega} e_n(t)e_n(t) dt = g(s).
\]

Therefore, \( k_n \rightharpoonup 0 \) and \( e_n \rightharpoonup 0 \) but \( B(k_n, e_n) = g \) for every \( n \).

Recently, in [30] it was proposed to study a variant of the problem by restricting the set of
vectors to the weakly compact set \( D \subset L^1 \), consisting on all the functions whose essential image
is contained in \([d_1, d_2]\), with \( 0 < d_1 < d_2 \). We see in the following example that, in the context
of integral operators, the weak-to-weak continuity of the bilinear mapping \( L^2 \times D \to L^1 \) is not
satisfied.

**Example 4.8.** On \( L^p(\Omega) \), \( \Omega = [0, 2\pi] \), consider the problem (RR-TLS) associated to an
integral operator,

\[
A_0 f(s) = \int_{\Omega} k_0(s, t) f(t) dt,
\]

where \( k_0 \in L^q(\Omega^2) \), for \( 1 \leq p, q < \infty \). We prove that, for some weakly compact subsets \( C \subset
L^q(\Omega^2) \) and \( D \subset L^p(\Omega) \), the bilinear mapping

\[
B : C \times D \to L^q(\Omega)(k, f) \mapsto B(k, f)(s) = \int_{\Omega} k(s, t) f(t) dt,
\]

is not weak-to-weak continuous.
In fact, let \( f_n(t) = 2 - \cos(nt) \in L^p([0, 2\pi]) \) and \( k_n(s, t) = 2 + \cos(nt) \in L^q([0, 2\pi]^2) \), for arbitrary \( p, q \). Note that both \( f_n \) and \( k_n \) are uniformly bounded above and below by 3 and 1 respectively, thus both sequences are contained in weakly compact sets. Moreover, since \( \cos(nt) \) converge weakly to 0 in \( L^p([0, 2\pi]) \) for any \( p \), we have that

\[
  f_n \xrightarrow{w} 2, \quad \text{and} \quad k_n \xrightarrow{w} 2,
\]

(where two denotes the constant function). Then

\[
  B(2, 2) = B(w - \lim k_n, w - \lim f_n) = \int_0^{2\pi} 4 = 8\pi.
\]

But, on the other hand,

\[
  B(k_n, f_n)(s) = \int_0^{2\pi} (2 + \cos(nt))(2 - \cos(nt))dt = 8\pi - \int_0^{2\pi} \cos^2(nt)dt = 7\pi.
\]

Therefore, \( B \) is not weak to weak continuous.

Note also that a similar reasoning may have been done when either \( p \) or \( q \) equal \( \infty \) replacing the weak topology by the weak* topology.

**Remark 4.9.** The above example shows, once again, that the existence of solution of (RRTLS) is a subtle problem. Indeed, since \( L^1(\Omega) \) has the Dunford–Pettis property, if we take in the above example \( C \) to be a weakly compact set of bounded operators on \( L^1(\Omega) \) (instead of a weakly compact set of kernels in \( L^q(\Omega^2) \)) then, by proposition 4.6, the bilinear mapping has the necessary continuity in order to prove the existence of solution of (RRTLS).

To assure the existence of solution for problem (RRTLS), in the case when non-reflexive spaces are involved, one would have to prove that the associated bilinear mapping is weak* continuous (or WOT-continuous in the case of \( L(\mathcal{H}) \)). Our last example shows that if we do not restrict the domain then the bilinear mapping \( B(X, y) = Xy \) lacks the desired continuity on a very general situation.

**Example 4.10.** Let \( E_0 \) be any infinite dimensional Banach space. Then, there is a weakly null net \( (y_\lambda) \), contained in the sphere of \( E_0 \). Take now \( y'_\lambda \in E_0' \) of norm 1 such that \( y'_\lambda(y_\lambda) = 1 \). By taking a subnet, we may suppose that \( y'_\lambda \) converge in the weak* topology to some \( y' \) in the closed unit ball of \( E_0' \). Take \( 0 \neq y_1 \in E_1 \). Then \( (y'_\lambda(y_1)) \) is a net in \( L(E_0, E_1) \) that is WOT-convergent to \( y'(\cdot)y_1 \). Moreover \( B(y'_\lambda(\cdot)y_1, y_\lambda) = y_1 \) for every \( \lambda \) and \( B(y'(\cdot)y_1, 0) = 0 \). Therefore \( B \) is not WOT× weak continuous.

**Acknowledgments**

We thank the anonymous referees for reading our manuscript and helping us to improve the presentation of this paper. Maximiliano Contino was supported by the UBA’s Strategic Research Fund 2018 and CONICET PIP 0168. Alejandra Maestripieri was supported by CONICET PIP 0168. Guillermia Fongi was supported by PICT 2017 0883. Santiago Muro was supported by ANPCyT-PICT 2018-04250 and CONICET-PIP 11220130100329CO.
Data availability statement

All data that support the findings of this study are included within the article (and any supplementary files).
