Abstract
A spinning particle in the Schwarzschild spacetime deviates from geodesic behavior because of its spin. A spinless particle also deviates from geodesic behavior when a test radiation field is superimposed on the Schwarzschild background: in fact the interaction with the radiation field, i.e. the absorption and re-emission of radiation, leads to a friction-like drag force responsible for the well-known effect which exists already in Newtonian gravity, the Poynting–Robertson effect. Here the Poynting–Robertson effect is extended to the case of spinning particles by modifying the Mathisson–Papapetrou model describing the motion of spinning test particles to account for the contribution of the radiation force. The resulting equations are numerically integrated and some typical orbits are shown in comparison with the spinless case. Furthermore, the interplay between spin and radiation forces is discussed by analyzing the deviation from circular geodesic motion on the equatorial plane when the contribution due to the radiation can also be treated as a small perturbation. Finally the estimate of the amount of radial variation from the geodesic radius is shown to be measurable in principle.

PACS number: 04.20.Cv

1. Introduction

The motion of classical spinning test particles in a given gravitational background is described by the well-known Mathisson–Papapetrou (MP) model \cite{1, 2}. Let $U^\alpha = \frac{d x^\alpha}{d \tau}$ be the timelike unit tangent vector to the ‘center of mass line’ $C_U$ of the spinning particle used to perform the multipole reduction, parametrized by the proper time $\tau$. The equations of motion
are

\begin{equation}
\frac{DP_\mu}{d\tau} = -\frac{1}{2} R^\mu_{\nu\alpha\beta} U^\nu S^\alpha\beta \equiv F^{(\text{spin})\mu}, \tag{1.1}
\end{equation}

\begin{equation}
\frac{DS^{\mu\nu}}{d\tau} = P^\mu U^\nu - P^\nu U^\mu, \tag{1.2}
\end{equation}

where $P^\mu$ is the total 4-momentum of the particle and the antisymmetric tensor $S^{\mu\nu}$ denotes the spin tensor (intrinsic angular momentum) associated with it; both fields are defined only along this center of mass world line. This system of 10 equations evolves $P$ and $S$ along $C_U$ but contains 13 unknown quantities: $U(3)$, $P(4)$, $S(6)$. Consistency of the model is ensured by imposing the Tulczyjew–Dixon [3–8] supplementary conditions

\begin{equation}
S^{\mu\nu} P_\nu = 0. \tag{1.3}
\end{equation}

Moreover, implicit in the model is the requirement that the spin structure of the particle should produce very small deviations from geodesic motion, in the sense that the length scale naturally associated with the spin should be very small when compared with the one associated with the curvature tensor of the spacetime itself. Otherwise, large values of spin would require taking into account the particle backreaction on the spacetime metric, i.e. the problem should be approached from a completely different point of view.

Let us consider a spinless test particle orbiting a star which emits radiation. The radiation pressure of the light emitted by the star, in addition to the direct effect of the outward radial force, exerts a drag force on the particle’s motion. This usually causes the body to fall into the star unless it is so small that the radiation pressure pushes it away from the star, a phenomenon called the Poynting–Robertson effect since it was first investigated by Poynting [9] using Newtonian gravity and then calculated in the framework of linearized general relativity by Robertson [10]. Successively many authors studied the Poynting–Robertson effect in more concrete situations, starting from the case of slowly evolving elliptical orbits for meteors [11], to more recent works [12–16], where rotation of the emitting star is taken into account. More recently the Poynting–Robertson effect for a spinless test particle orbiting a black hole was studied in both the Schwarzschild and Kerr spacetimes [17] without the restriction of slow motion, but ignoring the finite size of the radiating body.

Here we generalize the above discussion to the more realistic case of a spinning test particle subject to the Poynting–Robertson effect by including the radiation forces in the Mathisson–Papapetrou model. Today we have evidence of the existence of accreting matter around massive compact objects, e.g. active galactic nuclei [18]. The dynamical behavior of particles in close orbits around massive objects, while interacting with their radiation field, can be relevant when studying the evolution of shell or disk-like configurations of dust around intense radiative relativistic sources, where the loss of angular momentum via the Poynting–Robertson effect could act as a dust accretion mechanism. The radiation mechanism around a real accreting compact object is generally very complicated. We will limit ourselves to the case of a coherent flux of photons traveling along geodesics in some preferred direction. Possible scenarios include a hot neutron star, a black hole accreting radiation or a system with an accretion disk which radiates. When the approximation of point-like test particles is no longer valid, we expect that the real Poynting–Robertson effect offers a different behavior with respect to the standard Poynting–Robertson effect for small dust particles. The Mathisson–Papapetrou model allows us to take into account the actual size of the particle in the framework of general relativity by introducing a characteristic length of the particle itself through its spin.
It is worth mentioning that there also exists a wide literature concerning pseudo-classical test spinning particles, whose equations of motion reduce under certain limit to the classical MP equations [19–22]. In fact, spinning particles can be equivalently described by pseudo-classical mechanics models in which the spin degrees of freedom are characterized in terms of anticommuting Grassmann variables, associated—in the semiclassical limit—with the components of the spin tensor of the particle. The Lagrangian formulation can be used as well to study spinning particle motion in external fields. Here, however, we only consider classical test bodies, leaving for future work further generalizations of this analysis to the case of pseudo-classical particles.

2. Motion in the Schwarzschild spacetime

Consider a Schwarzschild spacetime whose line element written in standard coordinates is given by
\[ ds^2 = -N^2 dt^2 + N^{-2} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\phi^2), \] (2.1)
where \( N = (1 - 2M/r)^{1/2} \) denotes the lapse function, and introduces the usual orthonormal frame adapted to the static observers (or zero angular momentum observers, ZAMOs) following the time lines
\[ e_t = N^{-1} \partial_t, \quad e_r = \partial_r, \quad e_\theta = \frac{1}{r} \partial_\theta, \quad e_\phi = \frac{1}{r \sin \theta} \partial_\phi, \] (2.2)
where \{\partial_t, \partial_r, \partial_\theta, \partial_\phi\} is the coordinate frame.

We limit our analysis to the equatorial plane \( \theta = \pi/2 \), where the situation is relatively receptive to analytical treatment. As a convention, the physical (orthonormal) component along \(-\partial_\theta\) which is perpendicular to the equatorial plane will be referred to as ‘along the positive z-axis’ and will be indicated by the index \( \hat{z} \), when convenient: \( e_z = -e_\theta \).

2.1. Test particles subject to the Poynting–Robertson effect

Let a pure electromagnetic radiation field be superposed as a test field on the gravitational background described by metric (2.1), with the energy–momentum tensor
\[ T^{\alpha\beta} = \Phi^2 k^\alpha k^\beta, \quad k^\alpha k_\alpha = 0, \] (2.3)
where \( k \) is assumed to be tangent to an affinely parametrized outgoing null geodesic in the equatorial plane, i.e. \( k^\alpha \nabla_\alpha k^\beta = 0 \) with \( k^\alpha = 0 \).

We will only consider photons in the equatorial plane which are in outward radial motion with respect to the ZAMOs, namely with 4-momentum
\[ k = E(n)(n + e_z), \] (2.4)
where \( n = e_t \) is the ZAMO 4-velocity and \( E(n) = E/N \) is the relative energy of the photon as seen by the ZAMOs. Here \( E = -k_t \) is the conserved energy associated with the timelike Killing vector field \( \partial_t \). Note also that \( L = k_\phi = 0 \), i.e. the conserved angular momentum associated with the rotational Killing vector field \( \partial_\phi \) is assumed to vanish. This is consistent with having a non-rotating light source in a non-rotating spacetime.

Since \( k \) is completely determined, the coordinate dependence of the quantity \( \Phi \) then follows from the conservation equations \( T^{\alpha\beta} ; \beta = 0 \), and will only depend on \( r \) in the equatorial plane due to the axial symmetry. We find
\[ \Phi = \frac{\Phi_0}{r}. \] (2.5)
Consider now a test particle moving in the equatorial plane $\theta = \pi/2$ accelerated by the radiation field, i.e. with 4-velocity
\[
U = \gamma(U, n)[n + v(U, n)], \quad v(U, n) \equiv v^\rho e_\rho + v^\phi e_\phi = v(\sin \alpha e_r + \cos \alpha e_\phi),
\]
(2.6)
where $\gamma(U, n) = 1/\sqrt{1 - ||v(U, n)||^2}$ is the Lorentz factor and the abbreviated notation $v^\rho \equiv v(U, n)^\rho$ has been used. Similarly $v \equiv ||v(U, n)||$ and $\alpha$ are the magnitude of the spatial velocity $v(U, n)$ and its polar angle measured clockwise from the positive $\phi$ direction in the $r$–$\phi$ tangent plane respectively, while $\hat{\nu} \equiv \hat{v}(U, n)$ is the associated unit vector. Note that $\alpha = 0$ corresponds to azimuthal motion with respect to the ZAMOs, while $\alpha = \pm \pi/2$ corresponds to (outward/inward) radial motion with respect to the ZAMOs.

A straightforward calculation gives the coordinate components of $U$:
\[
U^t \equiv \frac{dt}{d\tau} = \frac{\gamma}{N}, \quad U^r \equiv \frac{dr}{d\tau} = \gamma N v^r, \quad U^\phi \equiv \frac{d\phi}{d\tau} = \frac{\gamma v^\phi}{r},
\]
(2.7)
where $\tau$ is the proper time parameter along $C_U$ and $U^\theta \equiv d\theta/d\tau = 0$. Solving these for the magnitude and polar angle leads to
\[
\tan \alpha = \frac{1}{N r} \frac{dr}{d\phi}, \quad v = \frac{1}{N^2} \sqrt{\left(\frac{dr}{d\tau}\right)^2 + N^2 r^2 \left(\frac{d\phi}{d\tau}\right)^2}.
\]
(2.8)

The scattering of radiation as well as the momentum-transfer cross section $\sigma$ (assumed to be a constant) of the particle is assumed to be independent of the direction and frequency of the radiation so that the associated force is given by [9, 10, 13]
\[
F^{(\text{rad})}_\alpha = -\sigma P_{\alpha \beta} T^{\beta \mu} U^\mu,
\]
(2.9)
where $P_{\alpha \beta} = \delta^\alpha_\beta + U^\alpha U_\beta$ projects orthogonally to $U$. Explicitly
\[
F^{(\text{rad})}_\alpha = -\sigma \Phi^2 (P(U)^\alpha_\beta k^\beta)(k_\mu U^\mu),
\]
(2.10)
implying
\[
F^{(\text{rad})} = \frac{m A}{N^2 r^2} \left(1 - v^t\right) \left[(v^t - v^r)^2 n + (1 - v^t - (v^\phi)^2) e_r - (1 - v^t)v^\phi e_\phi\right],
\]
(2.11)
where we have used the notation $\sigma \Phi^2 E^2 = mA$, as in [17]. Test particle motion is then described by the equation
\[
ma(U)^\mu \equiv m \frac{DU^\mu}{d\tau} = F^{(\text{rad})}_\mu,
\]
(2.12)
and has been studied in detail in [17].

2.2. Generalization to spinning particles

The most direct and simple generalization of equation (2.12) to the case of spinning test particles consists in including the radiation force term in equation (1.1), so that one has
\[
\frac{DP^\mu}{d\tau} = F^{(\text{spin})}_\mu + F^{(\text{rad})}_\mu,
\]
(2.13)
plus the additional relations (1.2) and (1.3) involving the spin. Let us proceed to analyze the motion of spinning particles subject to the Poynting–Robertson effect in the equatorial plane of the Schwarzschild spacetime.

The 4-momentum $P = mu$ for motion in the equatorial plane is
\[
u_a = \frac{1}{\sqrt{1 - v^t}}.
\]
(2.14)
We introduce the spin vector associated with $S_{\mu\nu}$ by the spatial duality
\[ S^\beta = u^\alpha \eta^{\beta \mu \nu} S_{\mu \nu}, \tag{2.15} \]
where $\eta^{\beta \mu \nu} = \sqrt{-g} \epsilon^{\beta \mu \nu \delta}$ is the unit volume 4-form and $\epsilon^{\beta \mu \nu \delta}$ ($\epsilon_{0123} = 1$) is the Levi-Civita alternating symbol. It is also useful to consider the scalar invariant
\[ s^2 = \frac{1}{2} S_{\mu \nu} S^{\mu \nu}, \tag{2.16} \]
constant along $C_U$ because of equations (1.2) and (1.3). Consistency of the model requires that the length scale $|s|/m$ associated with the spinning particle be much smaller than the one associated with the background spacetime, say $M$, namely
\[ |\hat{s}| \equiv \frac{|s|}{mM} \ll 1. \tag{2.17} \]

Let us consider equations (1.1) and (1.2) with $U^a$ given by equation (2.7) and $u^a$ given by equation (2.14). In the spinless case $P$ is aligned with $U$, i.e. $u = U$, implying that $\nu = \nu_u$. The presence of the spin causes a change in both $U$ and $u$ according to
\[ U = U_0 + \hat{s} U_\theta, \quad u = U_0 + \hat{s} u_\theta, \tag{2.18} \]
where
\[ U_0 = \gamma_0 \left( n + \nu_0 e_\theta + \nu_0 \hat{s} e_\phi \right) \tag{2.19} \]
satisfies equation (2.12) and corrections are first order in the spin. Higher order terms in equations (1.1) and (1.2) are neglected. This leads to two different sets of equations for zeroth and first order in spin respectively, which are listed in appendix A.

The spin force to first order in $\hat{s}$ is given by
\[ F^{(\text{spin})} = -\frac{3mM^2}{r_0^2} \hat{s} \gamma_0^2 \nu_0 \left( \nu_0 n + e_\theta \right). \tag{2.20} \]
We find that the mass of the spinning particle $m$ is a constant of motion. Furthermore, from the evolution equations for the spin it follows that the spin vector has a single nonvanishing and constant component along $\theta$ (or $z$), namely
\[ \hat{S} = -S^\theta e_\theta = s e_z. \tag{2.21} \]

Figures 1–3 show some numerical solutions for the orbits in the strong field region. Of course it only makes sense to consider the exterior solutions for radii larger than some minimum radius $R$ outside the horizon in order to model the geometry outside a star (or some other physical source) of radius $R$ producing the outflow of radiation.

In the case of spinless particles there exists a condition representing the balancing of the gravitational attraction and the radiation pressure at constant $r_0$ and $\phi_0$, namely
\[ F = \left( 1 - \frac{2M}{r_0} \right)^{1/2} \rightarrow r_0 = r_{(\text{crit})} = \frac{2M}{1 - A^2/M^2}. \tag{2.22} \]
This behavior also characterizes the motion of spinning particles as well, as shown in appendix A. Figures 1 and 2 show some typical solution curves starting initially with purely azimuthal velocity either inside (figure 1) or outside (figure 2) the critical radius at which a particle initially at rest with respect to the ZAMOs (which in turn are at rest with respect to the coordinate system) remains at rest. For comparison, the corresponding curves for spinless particles with the same initial data are also shown. If $A/M \ll 1$, the critical radius approaches the horizon $r_{(\text{crit})} \approx 2M$. For instance, an initially Keplerian circular orbit gradually spirals toward the central source, as illustrated in figure 3.
Figure 1. The orbit of a spinning particle (solid curve) subject to the Poynting–Robertson effect is shown for the choice of the parameters $A/M = 0.8$ and $\delta = 0.5$ ($X = r \cos \phi$ and $Y = r \sin \phi$ are the Cartesian-like coordinates). The starting point is located at $r_0(0) = 4M$ and $\phi_0(0) = 0$ with $v_{\nu(0)}(0) = 0.7$, $\alpha_{\nu(0)}(0) = 0$, $t_s(0) = 0$, $r_s(0) = 0$, and $\phi_s(0) = 0$, $v^\rho_s(0) = 0$ and $v^\phi_s(0) = 0$. The values of the spin parameter have been exaggerated in order to distinguish the difference from the motion of a spinless particle (dashed curve). The inner circle is at the horizon $r = 2M$, while the outer circle is at the critical radius $r_{\text{crit}} = 5.5M$ which is outside the initial data position.

Figure 2. The orbit of a spinning particle (solid curve) subject to the Poynting–Robertson effect is shown for the choice of the parameters $A/M = 0.6$ and $\delta = 0.5$. The starting point is located at $r_0(0) = 4M$ and $\phi_0(0) = 0$ with $v_{\nu(0)}(0) = 0.5$, $\alpha_{\nu(0)}(0) = 0$, $t_s(0) = 0$, $r_s(0) = 0$ and $\phi_s(0) = 0$, $v^\rho_s(0) = 0$ and $v^\phi_s(0) = 0$. The corresponding orbit for a spinless particle is also shown (dashed curve). The critical radius $r_{\text{crit}} = 3.125M$ is inside the initial data position.

3. Deviation from the circular geodesic

Consider now the corrections to geodesic circular motion, by taking the effect of the radiation field to also be small.
In the absence of both spin and radiation we assume the geodesic motion of the particle to be circular at $r = r_0$ ($r_0 > 3M$ in order $U_K$ to be timelike), that is

$$U = U_K = \gamma_K (n \pm v_K e_\phi), \quad (3.1)$$

where the Keplerian value of speed ($v_K$) and the associated Lorentz factor ($\gamma_K$) and angular velocity ($\zeta_K$) are given by

$$v_K = \sqrt{\frac{M}{r_0 - 2M}}, \quad \gamma_K = \sqrt{\frac{r_0 - 2M}{r_0 - 3M}}, \quad \zeta_K = \sqrt{\frac{M}{r_0}}. \quad (3.2)$$

The $\pm$ signs in equation (3.1) correspond to co-rotating ($+$) or counter-rotating ($-$) orbits with respect to increasing values of the azimuthal coordinate $\phi$ (counter-clockwise motion as seen from above). The azimuthal direction in the local rest space of $U_K$ pointing in the direction of relative motion (i.e. the boost of $e_\phi$ in the local rest space of $U_K$) is specified by the following unit vector orthogonal to $U_K$ in the $t-\phi$ plane:

$$\vec{U}_K = \gamma_K (v_K n \pm e_\phi), \quad (3.3)$$

where the $\pm$ signs are correlated with those in $U_K$.

The parametric equations of $U_K$ are

$$t_K = t_0 + \gamma_K N_0 \tau \equiv t_0 + \Gamma_K \tau, \quad r = r_0, \quad \theta = \frac{\pi}{2}, \quad \phi_K = \phi_0 \pm \gamma_K v_K \tau \equiv \phi_0 \pm \Omega_K \tau, \quad (3.4)$$

where now $t_0$, $r_0$ and $\phi_0$ are constants and

$$\Gamma_K = \sqrt{\frac{r_0}{r_0 - 3M}}, \quad \Omega_K = \frac{1}{r_0} \sqrt{\frac{M}{r_0 - 3M}}. \quad (3.5)$$
It is convenient to introduce a friction parameter $f$, so that the length scale $A$ associated with the radiation field is much smaller than $M$, i.e.

$$f \equiv \frac{A}{M} \ll 1.$$  

(3.6)

Therefore, in the present analysis corrections to geodesic motion will be limited to first-order terms in both parameters $\hat{s}$ and $f$, according to

$$t = t_K + f t_f + \hat{s} t_s, \quad r = r_0 + f r_f + \hat{s} r_s, \quad \phi = \phi_K + f \phi_f + \hat{s} \phi_s,$$

$$v^f = f v^f_f + \hat{s} v^f_s, \quad \dot{v}^f = \pm v^f_K + f \dot{v}^f_f + \hat{s} \dot{v}^f_s,$$

$$v_a = \pm v^a_K + f v^a_f + \hat{s} v^a_s, \quad \alpha_a = f \alpha^a_f + \hat{s} \alpha^a_s,$$

(3.7)

where $t_K$ and $\phi_K$ are given by equation (3.4). This implies

$$U = U_K + f U_f + \hat{s} U_s,$$

(3.8)

where

$$U_f = \left( -v^f_K \frac{r_f}{r_0} \pm \gamma^2_K v^f_s \right) \dot{U}_K + \gamma_K v^f_s e_f,$$

$$U_s = \left( -v^s_K \frac{r_s}{r_0} \pm \gamma^2_K v^s_s \right) \dot{U}_K + \gamma_K v^s_s e_s.$$

(3.9)

Similarly

$$u = U + f u_f + \hat{s} u_s,$$

with $U$ given by equation (3.8) and

$$u_f = \gamma_K \left( v^f_K v^f_s - v^s_K \right) e_f, \quad u_s = \gamma_K \left( v^s_K v^s_s - v^s_f \right) e_s,$$

(3.10)

as discussed in appendix B.

To first order in $\hat{s}$ and $f$ the spin force and radiation force are given by

$$F^{(\text{spin})} = \mp 3 m M \hat{s} \gamma^2_K \dot{v}^f_K e_f,$$

$$F^{(\text{rad})} = -m f \frac{\Omega}{\Omega_0} \left( \gamma_K v_k \dot{U}_K - e_f \right),$$

(3.12)

respectively. The ratio between the magnitudes of these forces has the form

$$\left| \frac{F^{(\text{spin})}}{F^{(\text{rad})}} \right| = \frac{3 |\hat{s}|}{f} \left( \frac{M}{r_0} \right)^{3/2} \sqrt{1 - \frac{3 M}{r_0}}.$$  

(3.13)

Its behavior as a function of $r_0$ in units of $|\hat{s}|/f$ is shown in figure 4.

The equations governing first-order perturbations are listed in appendix B. The corresponding solution is given by

$$v^f_s = \mp \frac{3 M^2 \Omega}{r_0} \Omega_{\text{cp}} \sin(\Omega_{\text{cp}} \tau),$$

$$v^f_f = \frac{v^f_K}{r_0 \Omega_{\text{cp}}} \left\{ \sin(\Omega_{\text{cp}} \tau) + 2 r_0 \xi_K \frac{\Omega_{\text{cp}}}{\Omega_{\text{cp}}} \left[ \cos(\Omega_{\text{cp}} \tau) - 1 \right] \right\},$$

$$v^f_s = \frac{3 M^2 \xi^2_K}{\Omega_{\text{cp}}^2} \dot{v}^f_s,$$

$$v^f_f = \pm \frac{3 M^2 \xi^2_K}{r_0 \Omega_{\text{cp}}^2} \left\{ \frac{\xi_K}{r_0 \Omega_{\text{cp}}} \left[ \cos(\Omega_{\text{cp}} \tau) - 1 \right] - \frac{2 \xi_K}{\Omega_{\text{cp}}} \sin(\Omega_{\text{cp}} \tau) + \Omega_{\text{cp}} \dot{\xi}_K \right\},$$

(3.14)
Figure 4. The ratio between the magnitudes of spin and radiation forces given by equation (3.13) is plotted in units of $|\hat{s}|/f$ as a function of $r_0/M$. 

\[
\frac{|\hat{s}|/f}{|\hat{r}|/f} = \begin{array}{c}
\text{units of} |\hat{s}|/f \\
\text{as a function of} r_0/M.
\end{array}
\]

and

\[
t_i = \pm 6M^2 \frac{\Omega_k^2}{\Omega_{ep}^2} \left[ \sin(\Omega_{ep} \tau) - \Omega_{ep} \tau \right],
\]

\[
t_f = 4r_0 \xi K^2 \frac{\Omega_{ep}^2}{\Omega_{ep}^2} \left[ \cos(\Omega_{ep} \tau) - 1 \right] + \frac{\Omega_{ep}}{2r_0 \xi K \Omega_K} \left[ \sin(\Omega_{ep} \tau) - \Omega_{ep} \tau \right] + \frac{3}{8} \gamma K^2 \Omega_{ep}^2 \tau^2.
\]

\[
r_i = \pm 3r_0 \frac{\Omega_k \xi K}{\Omega_{ep}^2} [\cos(\Omega_{ep} \tau) - 1],
\]

\[
r_f = -r_0 \xi K \frac{\Omega_k}{\Omega_{ep}^2} \left[ \cos(\Omega_{ep} \tau) - 1 \right] - 2r_0 \xi K \frac{\Omega_k}{\Omega_{ep}^2} \left[ \sin(\Omega_{ep} \tau) - \Omega_{ep} \tau \right].
\]

\[
\phi_i = \pm \xi K \frac{v_k}{v_{ep}^2} t_i, \quad \phi_f = \pm \xi K \frac{v_k}{v_{ep}^2} t_f.
\]

where

\[
\Omega_{ep} = \sqrt{\frac{M(r_0 - 6M)}{r_0^2(r_0 - 3M)}}
\]

is the well-known epicyclic frequency governing the radial perturbations of circular geodesics.

The constant term in $r_i$ represents the slight change in the radius of the circular orbit about which the solution oscillates with proper period $2\pi/\Omega_{ep}$. In contrast, the presence of a secular term in $r_f$ is responsible for the deviation from geodesic motion due to friction, which is measurable in principle. In fact, by taking the mean values over a period of the perturbed radius we can estimate the amount of variation of the radial distance

\[
\langle \frac{\delta r}{r} \rangle \equiv \frac{r - r_0}{r_0} = \Gamma_K \frac{\xi K}{\Omega_{ep}^2} \left[ \left( 1 - 2\pi r_0 \xi K \frac{\Omega_k}{\Omega_{ep}} \right) f + 3M^2 \gamma K^2 \xi K N_0 \right].
\]

(3.17)
For instance, for the motion of the Earth about the Sun we find
\[
\frac{\delta r}{r} \approx f \mp 2 \times 10^{-17} \frac{(s/m)_\oplus}{\text{cm}} \approx 3 \times 10^{-5} \mp 4 \times 10^{-15} \approx 10^{-5},
\]
(3.18) since \( r_0 \approx 1.5 \times 10^{13} \text{ cm} \), \( M = M_\odot \approx 1.5 \times 10^5 \text{ cm} \) and the ratio \( (s/m)_\oplus \approx 200 \text{ cm} \) for the Earth; the friction parameter is related to the ratio between the solar luminosity \( L_\odot \approx 3.8 \times 10^{33} \text{ erg s}^{-1} \) and the Eddington luminosity \( L_{\text{Edd}} \approx 1.3 \times 10^{38} \text{ erg s}^{-1} \), and for the Sun is given by \( f \approx 3 \times 10^{-5} \). Therefore, in this case the effect of the radiation field on the orbit dominates. Note that the estimate of the contribution due to spin is in agreement with [23].

The effect of the spin may become important when the orbiting extended body is a fast rotating object. To illustrate the order of magnitude of the effect, we may consider the binary pulsar system PSR J0737-3039 as orbiting Sgr A*, the supermassive \( (M \simeq 10^6 M_\odot) \) black hole located at the Galactic Center [24, 25], at a distance of \( r \approx 10^9 \text{ Km} \). The PSR J0737-3039 system consists of two close neutron stars (their separation is only \( d_{AB} \approx 8 \times 10^5 \text{ Km} \) of comparable masses \( m_A \simeq 1.4 M_\odot, m_B \simeq 1.2 M_\odot \), but very different intrinsic spin period (23 ms of pulsar A versus 2.8 s of pulsar B) [26]. Its orbital period is about 2.4 h, the smallest yet known for such an object. Since the intrinsic rotations are negligible with respect to the orbital period, we can treat the binary system as a single object with reduced mass \( \mu_{AB} \simeq 0.7 M_\odot \) and intrinsic rotation equal to the orbital period. The spin parameter thus turns out to be equal to \( \hat{s} \approx 1.0 \times 10^{-3} \). The luminosity of Sgr A* is about \( 10^7 L_\odot \), whereas its Eddington luminosity is \( L_{\text{Edd}} \approx 10^{11} L_\odot \), so that \( f \approx 10^{-8} \) and
\[
\frac{\delta r}{r} \approx 7.6 \times 10^{-9} \mp 1.8 \times 10^{-7} \approx 10^{-7}.
\]
(3.19) Therefore, in this case the effect of the spin on the orbit dominates with respect to the friction due to the radiation field. It is worth noting that the actual orbit in this case has to maintain close to the reference circular geodesic.

The numerical estimates (3.18) and (3.19) of the radial deviation leading to a spiral behaviour should be considered as purely indicative of the real combined effect of friction and spin.

4. Concluding remarks

We have studied the motion of a classical spinning body in the field of a central radiating object. The model adopted is the standard Mathisson–Papapetrou model suitably modified by accounting for the contribution of the Poynting–Robertson radiation force in the equations of motion. We have numerically integrated the whole set of Mathisson–Papapetrou equations in the case of equatorial motion and coherent flux composed of radially emitted photons. The spin vector turns out to have only a constant nonvanishing component orthogonal to the motion plane. We have shown some typical solution orbits in comparison with the spinless case. The latter is characterized by the existence of a critical radius at which the balancing of the gravitational attraction and the radiation pressure occurs at constant radial and azimuthal coordinates depending on the strength of the radiation field. This feature has been proved to be maintained also in the presence of spin. Dust particles would congregate at this radius leading to rings of matter to form.

Furthermore, we have discussed the interplay between spin and radiation forces by analyzing the deviation from circular geodesic motion on the equatorial plane when also the contribution due to friction can be treated as a small perturbation. The features of the motion thus depend on two different parameters, the spin parameter and the friction parameter,
which are taken as small in order to avoid backreaction. The presence of the spin causes a slight change in the radius of the circular orbit about which the solution oscillates and an increase/decrease of the angular velocity depending on whether the particle is co/counter rotating (i.e. moving clockwise or anticlockwise with respect to the positive \( \phi \) direction, respectively). In contrast, the presence of a secular term in the radial deviation due to friction determines a spiraling behavior of the orbit. This leads to a (average) radial variation from the geodesic radius whose amount is measurable, at least in principle.

The model presented here allows us to account for the finite size of the particle subject to the Poynting–Robertson effect in a framework which is genuinely relativistic. Obviously, in order to be physically more realistic, the model should be further generalized to take into account, for instance, the finite size of the radiating source and the contribution of higher order multipoles in the description of the actual size of the orbiting body and its shape, e.g. by including quadrupolar terms in the Mathisson–Papapetrou equations of motion.

Acknowledgments

The authors are indebted to Professors R T Jantzen and L Stella for initiating the discussion of the Poynting–Robertson effect in general relativity. ICRANet is thanked for support.

Appendix A. Solving the MP equations: general case

The parametric equations for the center of mass line \( C_U \) are given by

\[
\begin{align*}
t &= t_0 + \dot{\tau} t_0, \\
r &= r_0 + \dot{\tau} r_0, \\
\phi &= \phi_0 + \dot{\phi} \phi_0,
\end{align*}
\]

so that

\[
\begin{align*}
v^t &= v^t_0 + \dot{\tau} v^t_0, \\
v^\phi &= v^\phi_0 + \dot{\tau} v^\phi_0,
\end{align*}
\]

where all quantities are functions of the proper time \( \tau \). A similar expansion holds for \( u \), i.e.

\[
\begin{align*}
u_u &= u_{0u} + \dot{\tau} u_{0u}, \\
\alpha_u &= \alpha_{0u} + \dot{\tau} \alpha_{0u},
\end{align*}
\]

where \( u_{0u} = v_{00} \). The first-order correction to \( u \) turns out to be

\[
u_u = \gamma_{0u} \left[ u_{0u} v_{0u} \mu + \left( -v_{0u}^t \alpha_{0u} + \cos \alpha_{0u} v_{0u} \right) e_t + \left( v_{0u}^\phi \alpha_{0u} + \sin \alpha_{0u} v_{0u} \right) e_\phi \right],
\]

where \( \gamma_{0u} \) projects orthogonally to \( U_0 \).

The zeroth-order quantities satisfy equation (2.12), i.e.

\[
\begin{align*}
\frac{d\gamma_{0u}}{d\tau} &= \gamma_{0u}, \\
\frac{d\gamma_{0u} v_{0u}}{d\tau} &= \gamma_{0u} N_0 v_{0u}, \\
\frac{d\phi_{0u}}{d\tau} &= \frac{\gamma_{0u} v_{0u}}{r_0}, \\
\frac{d\gamma_{0u}}{d\tau} &= -\frac{\sin \alpha_{0u}}{v_{0u}} \frac{\gamma_{0u}}{v_{0u}} + \frac{A v_{0u}^2}{M r_0} \left( 1 - v_{0u}^2 \right) \left( \sin \alpha_{0u} - v_{0u} \right), \\
\frac{d\alpha_{0u}}{d\tau} &= -\frac{\cos \alpha_{0u}}{v_{0u}} \frac{\gamma_{0u} v_{0u}^2}{v_{0u}^2} + \frac{A v_{0u}^2}{M r_0} \left( 1 - v_{0u}^2 \right),
\end{align*}
\]

where

\[
v_{0u} = v_{0u} \sin \alpha_{0u}, \quad v_{0u}^\phi = v_{0u} \cos \alpha_{0u},
\]

and the Keplerian value of speed \( v_K \) and the associated Lorentz factor \( \gamma_K \) and angular velocity \( \zeta_K \) have been introduced in equation (3.2).
The first-order quantities satisfy the equations

\[
\frac{dt}{d\tau} = \frac{\gamma_{00}}{N_0} \left[ \gamma_{00}^2 (v_0^2 v_0^\phi + v_0 v_0^2) - \frac{\nu}{r_0} r_3 \right],
\]

\[
\frac{dr}{d\tau} = \gamma_{00} \frac{r_0}{N_0} \left\{ \gamma_{00}^2 \left[ (1 - (v_0^\phi)^2) v_0^\phi + v_0 v_0^\phi v_0^2 \right] + \frac{\nu^2}{r_0} v_0^2 r_3 \right\},
\]

\[
\frac{d\phi}{d\tau} = \gamma_{00} \frac{r_0}{N_0} \left\{ \gamma_{00}^2 [v_0^2 v_0^\phi v_0^\phi + (1 - (v_0^\phi)^2) v_0^\phi] - \frac{\nu}{r_0} r_3 \right\},
\]

\[
\frac{dv_0^2}{d\tau} = - \left( \frac{N_0^2}{r_0^2} - \frac{\nu^2}{r_0^2} \right) \gamma_{00} \frac{r_0}{N_0} \left[ (1 - (v_0^\phi)^2) - \frac{N_0}{r_0^2 \gamma_0 \gamma_{00}} + A \frac{1 + N_0^2}{r_0^2 N_0^4} (1 - (v_0^\phi)^2) \right] r_3
\]

\[
+ \frac{N_0}{r_0^2 N_0} \left[ 1 + \gamma_{00}^2 (1 - (v_0^\phi)^2) \right] v_0^\phi - \frac{3 M \xi_c^2 \gamma_{00} v_0^\phi}{r_0^0} (1 - (v_0^\phi)^2)
\]

\[
+ \frac{2 A^2 M}{r_0^0 N_0^2} \gamma_{00} v_0^\phi (1 - (v_0^\phi)^2) + \frac{A M}{r_0^0 N_0^2} v_0^2 (1 - (v_0^\phi)^2) \right) v_0^\phi
\]

\[
\times \left[ \frac{2 N_0^2}{r_0^0 N_0} (1 - (v_0^\phi)^2) + 2 v_0^2 (1 - (v_0^\phi)^2) - \frac{N_0^2}{r_0^0 N_0} \right],
\]

\[
\frac{dv_0^\phi}{d\tau} = \left( \frac{N_0^2}{r_0^0} - \frac{\nu^2}{r_0^0} \right) \gamma_{00} v_0^\phi \frac{r_0}{N_0} \left[ A + \frac{1 + N_0^2}{r_0^0 N_0^4} (1 - (v_0^\phi)^2) \right] v_0^\phi r_3
\]

\[
- \left[ \frac{N_0}{r_0^0 \gamma_0 \gamma_{00}} \gamma_{00} (1 - (v_0^\phi)^2) \right] v_0^\phi v_0^\phi
\]

\[
- \frac{N_0}{r_0^0 \gamma_{00}} \gamma_{00} (1 - (v_0^\phi)^2) + \frac{A}{r_0^0 N_0^2} (1 - (v_0^\phi)^2) \right] v_0^\phi + 3 M \xi_c^2 \gamma_{00} v_0^\phi v_0^\phi
\]

\[
+ \frac{2 A^2 M}{r_0^0 N_0^2} \gamma_{00} (1 - (v_0^\phi)^2) (1 - (v_0^\phi)^2) - \nu^0 \right)
\]

\[
- \frac{A M}{r_0^0 N_0} \left[ 2 \gamma_{00} v_0^2 (1 - (v_0^\phi)^2) \frac{1 - (v_0^\phi)}{\gamma_0^2} + 3 v_0^2 \right]
\]

\[
- (1 - (v_0^\phi)) \left[ 1 + 5 v_0^\phi - 2 v_0^2 K^2 (1 - (v_0^\phi)^2) + \frac{1}{\gamma_0^2} \right].
\]

The remaining quantities \(v_{a3}\) and \(\alpha_{a3}\) are related to the first-order spatial velocities by the algebraic relations

\[
v_{a3} = \frac{A M}{r_0^2 N_0^2} \cos \alpha_{a0} (1 - (v_0^\phi)^2) + \sin \alpha_{a0} v_0^\phi + \cos \alpha_{a0} v_0^\phi,
\]

\[
\alpha_{a3} = \frac{A M}{r_0^2 N_0^2} \gamma_{00} (1 - (v_0^\phi)^2) (v_{a3} - \sin \alpha_{a0}) + \frac{\cos \alpha_{a0}}{v_0^\phi} - \sin \alpha_{a0} v_0^\phi.
\]

### A.1. Equilibrium solutions

In order to find an equilibrium position at a given point \((r, \tau), \pi/2, \phi(\tau))\) for values \(\tau \geq \tau_e\) of the proper time we have to impose first the conditions \(dr/d\tau = 0\) and \(d\phi/d\tau = 0\), which are fulfilled by \(v_0^\phi = 0 = v_0^\phi\) (i.e. \(v_{a0} = 0\)) and \(v_0^\phi = 0 = v_0^\phi\). Requiring their first derivatives with
respect to $\tau$ to be identically vanishing as well gives condition (2.22) from the zeroth-order equations (A.5). The first-order set (A.7) yields

$$\frac{dU}{dr} = -\frac{\nu_{K}^2}{r_{0}N_{0}}r_{3}, \quad \frac{d\nu}{dr} = 0, \quad \frac{d\phi}{dr} = 0,$$

$$0 = -\theta_{K}^{1 + \frac{N_{0}^{2}}{N_{0}^{2}} \left[ \frac{A}{M} - \frac{N_{0}^{2}}{r_{0}} \left( 1 - \frac{M}{N_{0}^{2}} \right) \right] r_{3},$$

$$0 = \frac{2AM}{r_{0}^{2}N_{0}^{2}}(A - MN_{0}).$$

The last condition is nothing but equation (2.22), whereas the previous one implies $r_{3} = 0$ at all values of the proper time. Equilibrium positions are thus characterized by

$$U = n, \quad P = m(n + M\tilde{s}\theta_{K}v_{K}e_{\phi}), \quad (A.10)$$

at $r = r_{(\text{crit})}$.

Appendix B. Solving the MP equations: the case of small $f$

The quantities of first order in $\tilde{s}$ satisfy equations (A.7) and (A.8) where terms proportional to $f\tilde{s}$ are also neglected, taking into account that

$$\nu_{0} = 0, \quad \phi_{0} = \pm v_{K} = \nu_{0}, \quad \gamma_{0} = \gamma_{K}, \quad \alpha_{0} = 0, \quad (B.1)$$

according to equation (3.7). We have

$$\frac{dU}{dr} = \frac{\gamma_{K}}{N_{0}}\left[ \pm \gamma_{K}^{2}v_{K}\phi_{f} = \frac{\nu_{K}^{2}}{r_{0}}r_{3} \right],$$

$$\frac{d\nu}{dr} = \gamma_{K}N_{0}\nu_{f},$$

$$\frac{d\phi}{dr} = \gamma_{K}r_{0}\left[ \gamma_{K}^{2}v_{K}\phi_{f} = \frac{\nu_{K}^{2}}{r_{0}}r_{3} \right].$$

(B.2)

The remaining quantities $\nu_{a}$ and $\alpha_{a}$ are related to the first-order spatial velocities by the algebraic relations

$$\nu_{a} = \nu_{f}, \quad \alpha_{a} = \pm \frac{\nu_{f}}{\nu_{K}}.$$

(B.3)

The equations for the quantities of first order in $f$ come from the linearization of equation (A.5), where terms proportional to $f\tilde{s}$ are also neglected:

$$\frac{dU}{dr} = \frac{\gamma_{K}v_{K}}{N_{0}}\left[ \pm \gamma_{K}^{2}v_{K}\phi_{f} = \frac{v_{K}}{r_{0}}r_{3} \right],$$

$$\frac{d\nu}{dr} = \gamma_{K}N_{0}\nu_{f},$$

$$\frac{d\phi}{dr} = \gamma_{K}r_{0}\left[ \gamma_{K}^{2}v_{K}\phi_{f} = \frac{v_{K}}{r_{0}}r_{3} \right].$$

(B.4)
derivative of the equations for the first-order radial components of the spatial velocity with
\[ \frac{d\nu_f^r}{dr} = \gamma_K \frac{\nu_f^2}{r_0 N_0} r_f \pm 2 \gamma_K \zeta K \nu_f^\phi + \frac{\nu_f^2}{r_0}. \]
\[ \frac{d\nu_f^\phi}{dr} = \pm \left[ \frac{\zeta K}{\nu_f} v_f^r + \frac{\nu_f^3}{r_0} \right]. \]  

Finally, the remaining quantities \(\nu_{af}\) and \(\alpha_{af}\) turn out to be simply given by
\[ \nu_{af} = \nu_f^\phi, \quad \alpha_{af} = \pm \frac{\nu_f^r}{\nu_f}. \]

We now have to solve the coupled system of equations (B.2) and (B.4). Taking the derivative of the equations for the first-order radial components of the spatial velocity with respect to proper time yields
\[ \frac{d^2\nu_f^r}{d\tau^2} + \Omega_{ep}^2 \nu_f^r = 0, \quad \frac{d^2\nu_f^\phi}{d\tau^2} + \Omega_{ep}^2 \nu_f^\phi + 2 \Gamma_K \nu_f^2 \zeta K = 0, \]  

where the epicyclic frequency \(\Omega_{ep}\) has been introduced in equation (3.16). The general solution of equation (B.6) is straightforward
\[ \nu_f^r = a_1 \sin(\Omega_{ep} \tau) + a_2 \cos(\Omega_{ep} \tau), \]
\[ \nu_f^\phi = b_1 \sin(\Omega_{ep} \tau) + b_2 \cos(\Omega_{ep} \tau) - 2 \Gamma_K \nu_f^2 \frac{\zeta K}{\Omega_{ep}^2}. \]  

The first-order azimuthal components of the spatial velocity are then given by
\[ \nu_f^\phi = \pm \frac{\zeta K}{\nu_f} \left[ a_1 \cos(\Omega_{ep} \tau) - a_2 \sin(\Omega_{ep} \tau) \right] \mp \frac{3}{2} \frac{\nu_f^2}{r_0 N_0} \zeta K \nu_f^2, \]
\[ \nu_f^\phi = \pm \frac{\zeta K}{\nu_f} \left[ b_1 \sin(\Omega_{ep} \tau) - b_2 \cos(\Omega_{ep} \tau) \right] \mp \frac{3}{2} \frac{\nu_f^2}{r_0 N_0} \left[ \zeta K \nu_f^2 + \frac{2}{3} \nu_f^2 \zeta K \right]. \]  

Finally, the first-order corrections to the orbit turn out to be
\[ t_f = 2 r_0 \left[ b_1 \sin(\Omega_{ep} \tau) + b_2 \cos(\Omega_{ep} \tau) \right] - \frac{3}{2} \frac{\nu_f^2}{r_0 N_0} \left[ \zeta K \nu_f^2 + \frac{2}{3} \nu_f^2 \zeta K \right] \tau + d_1, \]
\[ r_f = \frac{N_0 \gamma_K}{\Omega_{ep}} \left[ a_1 \sin(\Omega_{ep} \tau) - a_1 \cos(\Omega_{ep} \tau) \right] + c_1, \]
\[ r_f = \frac{N_0 \gamma_K}{\Omega_{ep}} \left[ b_2 \sin(\Omega_{ep} \tau) - b_1 \cos(\Omega_{ep} \tau) \right] - \frac{2 M}{r_0} \frac{\Omega_{ep}^2}{\nu_f^2} \tau + c_2, \]
\[ \phi_f = \frac{2 \gamma_K}{r_0 N_0} \left[ a_1 \sin(\Omega_{ep} \tau) + a_2 \cos(\Omega_{ep} \tau) \right] \mp \frac{3}{2} \frac{\nu_f^2}{r_0 N_0} \zeta K \nu_f^2 \tau + e_1, \]
\[ \phi_f = \frac{2 \gamma_K}{r_0 N_0} \left[ b_1 \sin(\Omega_{ep} \tau) + b_2 \cos(\Omega_{ep} \tau) \right] + \frac{\nu_f^2}{r_0 N_0} \left[ \zeta K \nu_f^2 + \frac{2}{3} \nu_f^2 \zeta K \right] \tau + e_2, \]  

where \(a_1, a_2, b_1, b_2, c_1, c_2, d_1, d_2, e_1, e_2\) are the arbitrary integration constants. Their values are fixed by requiring that all first-order quantities vanish at \(\tau = 0\). The corresponding solution is given by equations (3.14) and (3.15).
