LOW RANK ESTIMATION OF SMOOTH KERNELS ON GRAPHS

BY VLADIMIR KOLTCHINSKII1 AND PEDRO RANGEL2

Georgia Institute of Technology

Let \((V, A)\) be a weighted graph with a finite vertex set \(V\), with a symmetric matrix of nonnegative weights \(A\) and with Laplacian \(\Delta\). Let \(S_*: V \times V \mapsto \mathbb{R}\) be a symmetric kernel defined on the vertex set \(V\). Consider \(n\) i.i.d. observations \((X_j, X'_j, Y_j)\), \(j = 1, \ldots, n\), where \(X_j, X'_j\) are independent random vertices sampled from the uniform distribution in \(V\) and \(Y_j \in \mathbb{R}\) is a real valued response variable such that \(E(Y_j|X_j, X'_j) = S_*(X_j, X'_j), j = 1, \ldots, n\). The goal is to estimate the kernel \(S_*\) based on the data \((X_1, X'_1, Y_1), \ldots, (X_n, X'_n, Y_n)\) and under the assumption that \(S_*\) is low rank and, at the same time, smooth on the graph (the smoothness being characterized by discrete Sobolev norms defined in terms of the graph Laplacian). We obtain several results for such problems including minimax lower bounds on the \(L_2\)-error and upper bounds for penalized least squares estimators both with nonconvex and with convex penalties.

1. Introduction. We study a problem of estimation of a symmetric kernel \(S_*: V \times V \mapsto \mathbb{R}\) defined on a large weighted graph with a vertex set \(V\) and \(m := \text{card}(V)\) based on a finite number of noisy linear measurements of \(S_*\). For simplicity, assume that these are the measurements of randomly picked entries of \(m \times m\) matrix \((S_*(u, v))_{u, v \in V}\), which is a standard sampling model in matrix completion. More precisely, let \((X_j, X'_j, Y_j), j = 1, \ldots, n\) be \(n\) independent copies of a random triple \((X, X', Y)\), where \(X, X'\) are independent random vertices sampled from the uniform distribution \(\Pi\) in \(V\), and \(Y \in \mathbb{R}\) is a “measurement” of the kernel \(S_*\) at a random location \((X, X')\) in the sense that \(E(Y|X, X') = S_*(X, X')\). In what follows, we assume that, for some constant \(a > 0\), \(|Y| \leq a\) a.s., which implies that \(|S_*(u, v)| \leq a, u, v \in V\).
The target kernel $S_*$ is to be estimated based on its i.i.d. measurements $(X_j, X'_j, Y_j), j = 1, \ldots, n$. We would like to study this problem in the case when the target kernel $S_*$ is, on the one hand, “low rank” [i.e., \(\text{rank}(S_*)\) is relatively small compared to \(m\)], and on the other hand, it is “smooth” in the sense that its “Sobolev-type norm” is not too large. Discrete versions of Sobolev norms can be defined for functions and kernels on weighted graphs in terms of their graph Laplacians. The problem of estimation of smooth low-rank kernels is of importance in a number of applications, such as learning kernels representing and predicting similarities between objects, various classification problems in large complex networks (e.g., edge sign prediction) as well as matrix completion problems in the design of recommender systems (collaborative filtering). Our main motivation, however, is mostly theoretical: we would like to explore to which extent taking into account smoothness of the target kernel could improve the existing methods of low rank recovery.

We introduce some notation used throughout the paper. Let $S_V$ be the linear space of symmetric kernels $S: V \times V \mapsto \mathbb{R}, S(u,v) = S(v,u), u, v \in V$ (or, equivalently, symmetric $m \times m$ matrices with real entries). Given $S \in S_V$, we use the notation \(\text{rank}(S)\) for the rank of $S$ and \(\text{tr}(S)\) for its trace. For two functions $f, g: V \mapsto \mathbb{R}, (f \otimes g)(u,v) := f(u)g(v)$. Suppose that $S = \sum_{j=1}^{r} \mu_j (\psi_j \otimes \psi_j)$ is the spectral representation of $S$ with $r = \text{rank}(S)$, $\mu_1, \ldots, \mu_r$ being nonzero eigenvalues of $S$ repeated with their multiplicities and $\psi_1, \ldots, \psi_r$ being the corresponding orthonormal eigenfunctions (obviously, there are multiple choices of $\psi_j$s in the case of repeated eigenvalues). We will define $\text{sign}(S)$ as $\text{sign}(S) := \sum_{j=1}^{r} \text{sign}(\mu_j)(\psi_j \otimes \psi_j)$ and the support of $S$ as $\text{supp}(S) := \text{l.s.}\{\psi_1, \ldots, \psi_r\}$. For $1 \leq p < \infty$, define the Schatten $p$-norm of $S$ as $\|S\|_p := (\text{tr}(\|S\|^p))^{1/p} = (\sum_{j=1}^{r} |\mu_j|^p)^{1/p}$, where $|S| := \sqrt{S^2}$. For $p = 1$, $\| \cdot \|_1$ is also called the nuclear norm and, for $p = 2$, $\| \cdot \|_2$ is called the Hilbert–Schmidt norm. This norm is induced by the Hilbert–Schmidt inner product which will be denoted by $\langle \cdot, \cdot \rangle$. The operator norm of $S$ is defined as $\|S\| := \max_j |\mu_j|$.

Let $\Pi^2 := \Pi \otimes \Pi$ be the distribution of random couple $(X, X')$. The $L_2(\Pi^2)$-norm of kernel $S$,

$$\|S\|_{L_2(\Pi^2)}^2 = \int_{V \times V} |S(u,v)|^2 \Pi^2(du, dv) = \mathbb{E}|S(X, X')|^2,$$

is naturally related to the sampling model studied in the paper, and it will be used to measure the estimation error. Denote by $\langle \cdot, \cdot \rangle_{L_2(\Pi^2)}$ the

---

3“l.s.” means “the linear span.”

4With some abuse of notation, we also denote occasionally the canonical Euclidean inner product in $\mathbb{R}^V$ by $\langle \cdot, \cdot \rangle$ and the corresponding Euclidean norm by $\| \cdot \|$.
corresponding inner product. Since $\Pi$ is the uniform distribution in $V$, $\|S\|_{L^2(\mathbb{R}^2)}^2 = m^{-2}\|S\|^2_2$ and $\langle S_1, S_2 \rangle_{L^2(\mathbb{R}^2)} = m^{-2}\langle S_1, S_2 \rangle$. In what follows, it will be often more convenient to use these rescaled versions rather than the actual Hilbert–Schmidt norm or inner product.

We will denote by $\{e_v : v \in V\}$ the canonical orthonormal basis of the space $\mathbb{R}^V$. Based on this basis, one can construct matrices $E_{u,v} = E_{v,u} = \frac{1}{2}(e_u \otimes e_v + e_v \otimes e_u)$. If $v_1, \ldots, v_m$ is an arbitrary ordering of the vertices in $V$, then $\{E_{v_j,v_j} : j = 1, \ldots, m\} \cup \{\sqrt{2}E_{v_i,v_j} : 1 \leq i < j \leq m\}$ is an orthonormal basis of the space $\mathcal{S}_V$ of symmetric matrices with Hilbert–Schmidt inner product.

In standard matrix completion problems, $V$ is a finite set with no further structure (i.e., the set of edges of the graph or the weight matrix are not specified). In the noiseless matrix completion problems, the target matrix $S_*$ is to be recovered from the measurements $(X_j, X'_j, Y_j), j = 1, \ldots, n$, where $Y_j = S_*(X_j, X'_j)$. The following method is based on nuclear norm minimization over the space of all matrices that “agree” with the data

$$\hat{S} := \text{argmin}\{\|S\|_1 : S \in \mathcal{S}_V, S(X_j, X'_j) = Y_j, j = 1, \ldots, n\},$$

It has been studied in detail in the recent literature; see [3, 4, 7, 14] and references therein. Clearly, there are low rank matrices $S_*$ that cannot be recovered based on a random sample of $n$ entries unless $n$ is comparable with the total number of the entries of the matrix. For instance, for given $u, v \in V$, let $S_* = E_{u,v}$. Then, rank($S_*$) $\leq 2$. However, the probability that the only two nonzero entries of $S_*$ are not present in the sample is $(1 - \frac{1}{m^2})^n$, and it is close to 1 when $n = o(m^2)$. In this case, the matrix $S_*$ cannot be recovered.

So-called low coherence assumptions have been developed to define classes of “generic” matrices that are not “low rank” and “sparse” at the same time and for which noiseless low rank recovery is possible with a relatively small number of measurements. For a linear subspace $L \subset \mathbb{R}^V$, let $L^\perp$ be the orthogonal complement of $L$ and let $P_L$ be the orthogonal projector onto the subspace $L$. Denote $L := \text{supp}(S_*), r = \text{rank}(S_*)$. A coherence coefficient is a constant $\nu \geq 1$ such that

$$\|P_L e_v\|^2 \leq \frac{\nu r}{m}, \quad v \in V \quad \text{and}$$

$$|\langle \text{sign}(S_*) e_u, e_v \rangle|^2 \leq \frac{\nu r}{m^2}, \quad u, v \in V$$

(it is easy to see that $\nu$ cannot be smaller than 1).

The following highly nontrivial result is essentially due to Candes and Tao [4] (a version stated here is due to Gross [7] and it is an improvement of the initial result of Candes and Tao). It shows that target matrices of “low coherence” (for which $\nu$ is a relatively small constant) can be recovered exactly using the nuclear norm minimization algorithm (1.1) provided that the number of observed entries is of the order $mr$ (up to a log factor).
Theorem 1. Suppose conditions (1.2) hold for some $\nu \geq 1$. Then, there exists a numerical constant $C > 0$ such that, for all $n \geq C \nu r m \log^2 m$, $\hat{S} = S_*$ with probability at least $1 - m^{-2}$.

In the case of noisy matrix completion, a matrix version of LASSO is based on a trade-off between fitting the target matrix to the data using least squares and minimizing the nuclear norm

$$
\hat{S} := \arg\min_{S \in S} \left[ n^{-1} \sum_{j=1}^{n} (Y_j - S(X_j, X'_j))^2 + \varepsilon \|S\|_1 \right].
$$

This method and its modifications have been studied by a number of authors; see [2, 9, 10, 13, 15]. The following low-rank oracle inequality was proved in [10] (Theorem 4) for a “linearized version” of the matrix LASSO estimator $\hat{S}$. Assume that, for some constant $a > 0$, $|Y| \leq a$ a.s. Let $t > 0$ and suppose that $\varepsilon \geq 4a(\sqrt{\frac{1 + \log(2m)}{nm}} \vee \frac{2(t + \log(2m))}{n})$. Then, there exists a constant $C > 0$ such that with probability at least $1 - e^{-t}$

$$
\|\hat{S} - S_*\|_{L^2(\Pi^2)}^2 \leq \inf_{S \in \mathcal{S}} \left[ \|S - S_*\|_{L^2(\Pi^2)}^2 + C m^2 \varepsilon^2 \operatorname{rank}(S) \right].
$$

In particular, $\|\hat{S} - S_*\|_{L^2(\Pi^2)}^2 \leq C m^2 \varepsilon^2 \operatorname{rank}(S_*)$. Very recently, the last bound was proved in [8] for the matrix LASSO estimator (1.3) itself in the case when the domain of optimization problem is $\{S : \|S\|_{L^\infty} \leq a\}$, where $\|S\|_{L^\infty} := \max_{u,v \in V} |S(u, v)|$; in fact, both [10] and [8] dealt with the case of rectangular matrices.

In the current paper, we are more interested in the case when the target kernel $S_*$ is defined on the set $V$ of vertices of a weighted graph $G = (V, A)$ with a symmetric matrix $A := (a(u, v))_{u,v \in V}$ of nonnegative weights. This allows one to define the notion of graph Laplacian and to introduce discrete Sobolev norms characterizing smoothness of functions on $V$ as well as symmetric kernels on $V \times V$. Denote $\deg(u) := \sum_{v \in V} a(u, v)$, $u \in V$. It is common in graph theory to call $\deg(u)$ the degree of vertex $u$. Let $D$ be the diagonal $m \times m$ matrix (kernel) with the degrees of vertices on the diagonal (it is assumed that the vertices of the graph have been ordered in an arbitrary, but fixed way). The Laplacian of the weighted graph $G$ is defined as $\Delta := D - A$. Denote $\langle \cdot, \cdot \rangle$ the canonical Euclidean inner product in the $m$-dimensional space $\mathbb{R}^V$ of functions $f : V \mapsto \mathbb{R}$ and let $\| \cdot \|$ be the corresponding norm. It is easy to see that

$$
\langle \Delta f, f \rangle = \frac{1}{2} \sum_{u,v \in V} a(u, v)(f(u) - f(v))^2,
$$

implying that $\Delta : \mathbb{R}^V \mapsto \mathbb{R}^V$ is a symmetric nonnegatively definite linear transformation. In a special case of a usual graph $(V, E)$ with vertex set
V and edge set \(E\), one defines \(A(u, v) = 1\) if and only if \(u \sim v\) (i.e., vertices \(u\) and \(v\) are connected with an edge) and \(A(u, v) = 0\) otherwise. In this case, \(\deg(u)\) is the number of edges incident to the vertex \(u\) and \(\langle \Delta f, f \rangle = \sum_{u \sim v} (f(u) - f(v))^2\). The notion of graph Laplacian allows one to define discrete Sobolev norms \(\|\Delta^{q/2} f\|, q > 0\) for functions on the vertex set of the graph and thus to describe their smoothness on the graph. Given a symmetric kernel \(S: V \times V \mapsto \mathbb{R}\), one can also describe its smoothness in terms of the norms \(\|\Delta^{q/2} S\|_2\). Suppose \(S\) has the following spectral representation: \(S = \sum_{j=1}^{m} \mu_j (\psi_j \otimes \psi_j)\), where \(\mu_j, j = 1, \ldots, m\) are the eigenvalues of \(S\) (repeated with their multiplicities) and \(\psi_j, j = 1, \ldots, m\) are the corresponding orthonormal eigenfunctions in \(\mathbb{R}^V\), then

\[
\|\Delta^{q/2} S\|^2_2 = \text{tr}(\Delta^{q/2} S^2 \Delta^{q/2}) = \text{tr}(\Delta^q S^2) = \sum_{j=1}^{m} \mu_j^2 \langle \Delta^{q/2} \psi_j, \psi_j \rangle
\]

\[
= \sum_{j=1}^{m} \mu_j^2 \|\Delta^{q/2} \psi_j\|^2.
\]

Basically, it means that the smoothness of the kernel \(S\) depends on the smoothness of its eigenfunctions. In what follows, we will often use rescaled versions of Sobolev norms,

\[
\|\Delta^{q/2} f\|_{L^2(\Pi)} = m^{-1/2} \|\Delta^{q/2} f\|^2,
\]

\[
\|\Delta^{q/2} S\|_{L^2(\Pi^2)} = m^{-1} \|\Delta^{q/2} S\|_2.
\]

It will be convenient for our purposes to fix \(q > 0\) and to define a nonnegatively definite symmetric kernel \(W := \Delta^q\). We will characterize the smoothness of a kernel \(S \in \mathcal{S}_V\) by the squared Sobolev-type norm \(\|W^{1/2} S\|^2_{L^2(\Pi^2)}\). The kernel \(W\) will be fixed throughout the paper, and its spectral properties are crucial in our analysis.\(^5\) Assume that \(W\) has the following spectral representation \(W = \sum_{k=1}^{m} \lambda_k (\phi_k \otimes \phi_k)\), where \(0 \leq \lambda_1 \leq \cdots \leq \lambda_m\) are the eigenvalues repeated with their multiplicities, and \(\phi_1, \ldots, \phi_m\) are the corresponding orthonormal eigenfunctions (of course, there is a multiple choice of \(\phi_k\) in the case of repeated eigenvalues). Let \(k_0 := \min\{k \leq m : \lambda_k > 0\}\). We will assume in what follows that, for some constant \(c \geq 1\), \(\lambda_{k+1} \leq c \lambda_k\) for all \(k \geq k_0\). It will be also convenient to set \(\lambda_k := +\infty, k > m\).

Let \(\rho := \|W^{1/2} S_{\star}\|_{L^2(\Pi^2)}\) and \(r := \text{rank}(S_{\star})\). It is easy to show (see the proof of Theorem 4 below) that kernel \(S_{\star}\) can be approximated by the following kernel: \(S_{\star,l} := \sum_{i,j,l} \langle S_{\star} \phi_i, \phi_j \rangle (\phi_i \otimes \phi_j)\) with the approximation error

\[
\|S_{\star} - S_{\star,l}\|^2_{L^2(\Pi^2)} \leq \frac{2\rho^2}{\lambda_{l+1}}.
\]

\(^5\)In fact, the relationship of \(W\) to the graph and its Laplacian will be of little importance allowing, possibly, other interpretations of the problem.
Note that the kernel $S_{s,l}$ can be viewed as an $l \times l$ matrix (represented in the basis of eigenfunctions $\{\phi_j\}$) and rank($S_{s,l}$) $\leq r \wedge l$, so, one needs $\sim (r \wedge l)l$ parameters to characterize such matrices. Thus, one can expect, that such a kernel can be estimated, based on $n$ linear measurements, with the squared $L_2(\Pi^2)$-error of the order $\frac{a^2(r \wedge l)l}{n}$. Taking into account the bound on the approximation error (1.4) and optimizing with respect to $l = 1, \ldots, m$, it would be also natural to expect the following error rate in the problem of estimation of the target kernel $S_s$:

$$\min_{1 \leq l \leq m} \left[ \frac{a^2(r \wedge l)l}{n} \sqrt{\frac{\rho^2}{\lambda_{l+1}}} \right].$$

(1.5)

We will show that such a rate is attained (up to constants and log factors) for a version of least squares method with a nonconvex complexity penalty; see Section 3. This method is not computationally tractable, so, we also study another method, based on convex penalization with a combination of nuclear norm and squared Sobolev type norm, and show that the rates are attained for such a method, too, provided that the target matrix satisfies a version low coherence assumption with respect to the basis of eigenfunctions of $W$. More precisely, we will prove error bounds involving so called coherence function $\varphi(S_s; \lambda) := \langle P_{\text{supp}(S_s)}, \sum_{\lambda_j \leq \lambda} (\phi_j \otimes \phi_j) \rangle$, that characterizes the relationship between the kernel $W$ defining the smoothness and the target kernel $S_s$; see Section 4 for more details; see also [11] for similar results in the case of “linearized least squares” estimator with double penalization. Finally, we prove minimax lower bounds on the error rate that are roughly of the order $\max_{1 \leq l \leq m} [\frac{a^2(r \wedge l)l}{n} \wedge \frac{\rho^2}{\lambda_l}]$ (subject to some extra conditions and with additional terms; see Section 2). In typical situations, this expression is, up to a constant, of the same order as the upper bound (1.5). For instance, if $\lambda_l \asymp l^{2 \beta}$ for some $\beta > 1/2$, then the minimax error rate of estimation of the target kernel $S_s$ is of the order

$$\left( \left( \frac{a^2r^{1/\beta}m}{n} \right)^{2\beta/(2\beta+1)} \wedge \left( \frac{a^2 \rho^{2/\beta}m}{n} \right)^{\beta/(\beta+1)} \wedge \frac{a^2rm}{n} \right) \sqrt{\frac{a^2}{n}}$$

(up to log factors). When $m$ is sufficiently large, the term $\frac{a^2rm}{n}$ will be dropped from the minimum, and we end up with a nonparametric convergence rate controlled by the smoothness parameter $\beta$ and the rank $r$ of the target matrix $S_s$ (the dependence on $m$ in the first two terms of the minimum is only in the log factors).

The focus of the paper is on the matrix completion problems with uniform random design, but it is very straightforward to extend the results of the following sections to sampling models with more general design distributions discussed in the literature on low rank recovery (such as, e.g., the models of random linear measurements studied in [9, 10]). It is also not hard to
replace the range $a$ of the response variable $Y$ by the standard deviation of the noise in the upper and lower bounds obtained below. This is often done in the literature on low-rank recovery, and it can be easily extended to the framework discussed in the paper by modifying our proofs. We have not discussed this in the paper due to the lack of space.

2. Minimax lower bounds. In this section, we derive minimax lower bounds on the $L_2(\Pi^2)$-error of an arbitrary estimator $\hat{S}$ of the target kernel $S_*$ under the assumptions that the response variable $Y$ is bounded by a constant $a > 0$, the rank of $S_*$ is bounded by $r \leq m$ and its Sobolev norm $\|W^{1/2}S_*\|_{L_2(\Pi^2)}$ is bounded by $\rho > 0$. More precisely, given $r = 1, \ldots, m$ and $\rho > 0$, denote by $S_{r, \rho}$ the set of all symmetric kernels $S: V \times V \mapsto \mathbb{R}$ such that $\text{rank}(S) \leq r$ and $\|W^{1/2}S\|_{L_2(\Pi^2)} \leq \rho$. Given $r, \rho$ and $a > 0$, let $\mathcal{P}_{r, \rho, a}$ be the set of all probability distributions of $(X, X', Y)$ such that $(X, X')$ is uniformly distributed in $V \times V$, $|Y| \leq a$ a.s. and $\mathbb{E}(Y|X, X') = S_*(X, X')$, where $S_* \in S_{r, \rho}$. For $P \in \mathcal{P}_{r, \rho, a}$, denote $S_P(X, X') := \mathbb{E}_P(Y|X, X')$.

Recall that $\{\phi_j, j = 1, \ldots, m\}$ are the eigenfunctions of $W$ orthonormal in the space $(\mathbb{R}^V, \langle \cdot, \cdot \rangle)$. Then $\bar{\phi}_j := \sqrt{m}\phi_j, j = 1, \ldots, m$ are orthonormal in $L_2(\Pi)$.

We will obtain minimax lower bounds for classes of distributions $\mathcal{P}_{r, \rho, a}$ in two different cases. Define $Q_p := \max_{1 \leq j \leq m} \|\bar{\phi}_j\|_{L_p(\Pi)}$. In the first case, we assume that, for some (relatively large) value of $p \geq 2$, the quantity $Q_p$ is not too large. Roughly, it means that most of the components of vectors $\phi_j \in \mathbb{R}^V$ are uniformly small, say, $\phi_j(v) \asymp m^{-1/2}, v \in V, j = 1, \ldots, m$. In other words, the $m \times m$ matrix $(\phi_j(v))_{j=1,\ldots,m,v \in V}$ is “dense,” so we refer to this case as a “dense case.” The opposite case is when this matrix is “sparse.” Its “sparsity” will be characterized by the quantity

$$d := \max_{v \in V} \text{card}\{j : \phi_j(v) \neq 0\},$$

which, in this case, should be relatively small. A typical example is the case when basis of eigenfunctions $\{\phi_j, j = 1, \ldots, m\}$ coincides with the canonical basis $\{e_v : v \in V\}$ of $\mathbb{R}^V$ (then, $d = 1$).

Denote $l_0 := k_0 \wedge 32$. In the dense case, the following theorem holds.

Theorem 2. Define

$$\delta_n^{(1)}(r, \rho, a) := \max_{l_0 \leq l \leq m} \left[ \frac{a^2(r \wedge l)!}{n} \wedge \frac{a^2(r \wedge l)^2}{l} \wedge \frac{1}{p-1} \frac{a^2(r \wedge l)}{Q_p^2} \wedge \frac{1}{m^{d/p}} \right].$$

There exist constants $c_1, c_2 > 0$ such that

$$\inf_{\hat{S}_n} \sup_{P \in \mathcal{P}_{r, \rho, a}} \mathbb{P}_P\{\|\hat{S}_n - S_P\|_{L_2(\Pi^2)} \geq c_1 \delta_n^{(1)}(r, \rho, a)\} \geq c_2,$$

where the infimum is taken over all the estimators $\hat{S}_n$ based on $n$ i.i.d. copies of $(X, X', Y)$.
In fact, it will follow from the proof that, if 
\[ \lambda_{k_0} \leq \frac{n \rho^2}{a^2 (r \wedge k_0) k_0} \] (i.e., the smallest nonzero eigenvalue of \( W \) is not too large), then the maximum in the definition of \( \delta_n^{(1)}(r, \rho, a) \) can be extended to all \( l = 1, \ldots, m \).

**Corollary 1.** Let
\[
\delta_n^{(2)}(r, \rho, a) := \max_{l_0 \leq l \leq m} \left[ \frac{a^2 (r \wedge l) l}{n} \wedge \frac{\rho^2}{\lambda_l} \wedge \frac{1}{Q_{\log m}^2} \frac{a^2 (r \wedge l)}{l} \wedge \frac{1}{\log m} \right].
\]
There exist constants \( c_1, c_2 > 0 \) such that
\[
\inf_{\hat{S}_n} \sup_{P \in P_{r, \rho, a}} \mathbb{P}\{\| \hat{S}_n - S_P \|_{L_2(\Pi^2)}^2 \geq c_1 \delta_n^{(2)}(r, \rho, a) \} \geq c_2.
\]

**Proof.** Take \( p = \log m \) in the statement of Theorem 2 and observe that
\[ m^{4/p} = e^4 \quad \text{and} \quad \frac{1}{p-1} \geq \frac{1}{\log m}. \]

**Remark.** It is easy to check that \( e^{-2} Q_\infty \leq Q_{\log m} \leq Q_\infty \).

It is obvious that one can replace the quantity \( \delta_n^{(1)}(r, \rho, a) \) in Theorem 2 [or the quantity \( \delta_n^{(2)}(r, \rho, a) \) in Corollary 1] by the following smaller quantity:
\[
\delta_n^{(3)}(r, \rho, a) := \max_{l_0 \leq l \leq \bar{l}} \left[ \frac{a^2 (r \wedge l) l}{n} \wedge \frac{\rho^2}{\lambda_l} \right],
\]
where \( \bar{l} := \left[ \frac{1}{Q_{pm^{2/p}}^2} \frac{n^{1/2}}{p-1} \wedge m \right] \). Moreover, denote
\[
\bar{l} := \max\left\{ l = l_0, \ldots, m : (r \wedge l) \lambda_l \leq \frac{\rho^2 n}{a^2} \right\}.
\]
It is straightforward to check that
\[
\max_{l_0 \leq l \leq m} \left[ \frac{a^2 (r \wedge l) l}{n} \wedge \frac{\rho^2}{\lambda_l} \right] = \frac{a^2 (r \wedge \bar{l} \bar{l})}{n} \wedge \frac{\rho^2}{\lambda_{\bar{l}+1}} \wedge \frac{\rho^2}{\lambda_{\bar{l}}}.
\]
and, if \( \bar{l} \leq L \), then \( \delta_n^{(3)}(r, \rho, a) = \frac{a^2 (r \wedge \bar{l} \bar{l})}{n} \wedge \frac{\rho^2}{\lambda_{\bar{l}+1}} \).

**Example.** Suppose that, for some \( \beta > 1/2, \lambda_l \asymp l^{2\beta}, l = 1, \ldots, m \) (in particular, it means that \( \lambda_l \neq 0 \) and \( l_0 = k_0 = 1 \)). Then, an easy computation shows that
\[
\bar{l} = (\bar{l} \wedge m) \vee 1, \quad \bar{l} \asymp (\frac{\rho^2 n}{a^2} \frac{1}{\bar{l}^{1/(2\beta+1)}}) \wedge (\frac{\rho^2 n}{a^2} \frac{1}{\bar{l}^{1/(2\beta+2)}}).
\]
Let \( p = \log m \) and take \( L := \left[ \frac{1}{Q_{p^2}} \frac{n^{1/2}}{\log(m/e)} \right] \wedge m \). The condition \( \bar{l} \leq L \) is satisfied, for instance, when either \( e^2 Q_{p^2} \sqrt{\log(m/e)} \left( \frac{\rho^2 n}{a^2} \right)^{1/(2\beta+1)} \leq c' n^{1/2-1/(2\beta+1)}, \)
or \( e^2 Q_p \sqrt{\log(m/e)} (\frac{\rho}{n})^{1/(\beta + 1)} \leq c' n^{1/2 - 1/(2\beta + 2)} \), where \( c' > 0 \) is a small enough constant (this, essentially, means that \( n \) is sufficiently large). Under either of these conditions, we get the following expression for a minimax lower bound:

\[
\left( \left( \frac{a^2 \rho^{1/\beta}}{n} \right)^{2\beta/(2\beta + 1)} \wedge \left( \frac{a^2 \rho^{2/\beta}}{n} \right)^{\beta/(\beta + 1)} \wedge \frac{a^2 r m}{n} \right) \vee \frac{a^2}{n}.
\]

(2.1)

We now turn to the sparse case.

**Theorem 3.** Let

\[
\delta_n^{(4)}(r, \rho, a) := \max_{l_0 \leq l \leq m} \left\{ \frac{a^2(r \wedge l)}{n} \wedge \frac{\rho^2}{\lambda_l} \wedge \frac{a^2 d}{d \log m m^2} \right\}.
\]

There exist constants \( c_1, c_2 > 0 \) such that

\[
\inf_{\hat{S}_n} \sup_{P \in \mathcal{P}_{r, \rho, a}} \mathbb{P}_P \{ \| \hat{S}_n - S_P \|_{L_2(\Pi^2)} \geq c_1 \delta_n^{(4)}(r, \rho, a) \} \geq c_2.
\]

It will be clear from the upper bounds of Section 3 (see the remark after Theorem 4) that, at least in a special case when \( \{ \phi_j \} \) coincides with the canonical basis of \( \mathbb{R}^V \), the additional term \( \frac{a^2 d}{d \log m m^2} \) is correct (up to a log factor). At the same time, most likely, the “third terms” of the bounds of Theorem 2 (in the dense case) and Theorem 3 (in the sparse case) have not reached their final form yet. A more sophisticated construction of “well separated” subsets of \( \mathcal{P}_{r, \rho, a} \) might be needed to achieve this goal. The main difficulty in the proof given below is related to the fact that we have to impose constraints, on the one hand, on the entries of the target matrix represented in the canonical basis and, on the other hand, on the Sobolev type norm \( \| W^{1/2}S \|_{L_2(\Pi^2)} \) (for which it is convenient to use the representation in the basis of eigenfunctions of \( W \)). Due to this fact, we are using the last representation in our construction, and we have to use an argument based on the properties of Rademacher sums to ensure that the entries of the matrix represented in the canonical basis are uniformly bounded by \( a \). This is the reason why the “third terms” occur in the bounds of Theorems 2 and 3. In this case, when the constraints are only on the norm \( \| W^{1/2}S \|_{L_2(\Pi^2)} \) and on the variance of the noise and there are no constraints on \( \| S \|_{L_\infty} \), it is much easier to prove the lower bound of the order \( \max_{l_0 \leq l \leq m} \left[ \frac{a^2(r \wedge l)}{n} \wedge \frac{\rho^2}{\lambda_l} \wedge \frac{a^2}{d \log m m^2} \right] \) without any additional terms. Note, however, that the condition \( \| S_\ast \|_{L_\infty} \leq a \) is of importance in the following sections to obtain the upper bounds for penalized least squares estimators that match the lower bounds up to log factors.

**Proof of Theorem 2.** The proof relies on several well-known facts stated below. In what follows, \( K(\mu \| \nu) := -\mathbb{E}_\mu \log \frac{d\nu}{d\mu} \) denotes Kullback–Leibler divergence between two probability measures \( \mu, \nu \) defined on the
same space and such that \( \nu \ll \mu \) (i.e., \( \nu \) is absolutely continuous with respect to \( \mu \)). We will denote by \( P^{\otimes n} \) the \( n \)-fold product measure \( P^{\otimes n} := P \otimes P \cdots \otimes P \). The following proposition is a version of Theorem 2.5 in [17].

**Proposition 1.** Let \( \mathcal{P} \) be a finite set of distributions of \((X, X', Y)\) such that the following assumptions hold:

1. there exists \( P_0 \in \mathcal{P} \) such that for all \( P \in \mathcal{P}, P \ll P_0 \);
2. there exists \( \alpha \in (0, 1/8) \) such that
   \[ \sum_{P \in \mathcal{P}} K(P_0^{\otimes n} \| P^{\otimes n}) \leq \alpha (\text{card}(\mathcal{P}) - 1) \log(\text{card}(\mathcal{P}) - 1); \]
3. for all \( P_1, P_2 \in \mathcal{P} \), \( \| S_{P_1} - S_{P_2} \|_{L^2(\Pi^2)}^2 \geq 4s^2 > 0 \).

Then, there exists a constant \( \beta > 0 \) such that

\[ (2.2) \quad \inf_{\hat{S}_n} \max_{P \in \mathcal{P}} \mathbb{P}\{ \| \hat{S}_n - S_P \|_{L^2(\Pi^2)} \geq s^2 \} \geq \beta > 0. \]

We will also use Varshamov–Gilbert bound (see [17], Lemma 2.9, page 104), Sauer’s lemma (see [9], page 39) and the following elementary bound for Rademacher sums (see [5], page 21): for all \( p \geq 2 \),

\[ (2.3) \quad \mathbb{E}^{1/p} \left| \sum_{j=1}^{N} \varepsilon_j t_j \right|^p \leq \sqrt{p-1} \left( \sum_{j=1}^{N} t_j^2 \right)^{1/2}, \quad (t_1, \ldots, t_N) \in \mathbb{R}^N, \]

where \( \varepsilon_1, \ldots, \varepsilon_N \) are i.i.d. Rademacher random variables (i.e., \( \varepsilon_j = +1 \) with probability 1/2 and \( \varepsilon_j = -1 \) with the same probability).

We will start the proof with constructing a “well separated” subset \( \mathcal{P} \) of the class of distributions \( \mathcal{P}_{r,a,a} \) that will allow us to use Proposition 1. Fix \( l \leq m, \ell \geq 32 \) and \( \kappa > 0 \). Denote \( l' = [l/2], l'' = l - l' \). First assume that \( r \leq l'' \).

Denote \( R_{\sigma} := \kappa((\sigma_{ij}) : i = 1, \ldots, l', j = 1, \ldots, r), \) where \( \sigma_{ij} = +1 \) or \( \sigma_{ij} = -1 \). Let \( \mathcal{R}_{l',r} = \{ R_{\sigma} : \sigma \in \{-1,1\}^{l' \times r} \} \) (so, \( \mathcal{R}_{l',r} \) is the class of all \( l' \times r \) matrices with entries \( +\kappa \) or \( -\kappa \)). Given \( R \in \mathcal{R}_{l',r} \), let

\[ \tilde{R} := \begin{pmatrix} R & R & \cdots & R & O_{l',r^*} \end{pmatrix}, \]

be the \( l' \times l'' \) matrix that consists of \( [l''/r] \) blocks \( R \) and the last block \( O_{l',r^*} \), where \( l^* := l'' - [l''/r] r \) and \( O_{k_1,k_2} \) is the \( k_1 \times k_2 \) zero matrix. Finally, define the following symmetric \( m \times m \) matrix:

\[ R^\otimes := \begin{pmatrix} O_{l',l'} & \tilde{R} & O_{l',m-l} \\ \tilde{R}^T & O_{l',l''} & O_{l',m-l} \\ O_{m-l,l'} & O_{m-l,l''} & O_{m-l, m-l} \end{pmatrix}. \]
Now, given \( \sigma \in \{-1,1\}^{r \times r} \), define a symmetric kernel \( K_\sigma : V \times V \mapsto \mathbb{R} \),

\[
K_\sigma := \sum_{i,j=1}^m (R^\sigma_{ij}) \phi_i \phi_j.
\]

It is easy to see that

\[
K_\sigma(u,v) = K'_\sigma(u,v) + K'_\sigma(v,u),
\]

(2.4)

\[
K'_\sigma(u,v) = \kappa \sum_{i,j=1}^{l'} \sum_{j} \sigma_{ij} \phi_i(u) \sum_{k=0}^{[l''/r]-1} \phi_{v+rk+j}(v).
\]

Let \( \Lambda := \{ \sigma \in \{-1,1\}^{l' \times r} : \max_{u,v \in V} |K_\sigma(u,v)| \leq a \} \). We will show that, if \( \kappa \) is sufficiently small (its precise value to be specified later), then the set \( \Lambda \) contains at least three quarters of the points of the combinatorial cube \( \{-1,1\}^{l' \times r} \). To this end, define \( \xi := \max_{u,v \in V} |K_\xi(u,v)| \), where \( \varepsilon \) is a random vector with i.i.d. Rademacher components. Assume, in addition, that \( \varepsilon \) and \((X,X')\) are independent. It is enough to show that \( \xi \leq a \) with probability at least 3/4. We have

\[
P\{\xi \geq a\} \leq \sum_{u,v \in V} P\{|K_\varepsilon(u,v)| \geq a\}
\]

(2.5)

\[
= m^2 \mathbb{E}P\{|K_\varepsilon(X,X')| \geq a|X,X'\}
\]

\[
= m^2 \mathbb{P}\{|K_\varepsilon(X,X')| \geq a\} \leq \frac{m^2 \mathbb{E}|K_\varepsilon(X,X')|^p}{a^p}.
\]

We will use bound (2.3) to control \( \mathbb{E}(|K_\varepsilon(X,X')|^p|X,X') \) [recall that \( K_\varepsilon(u,v), u,v \in V \) is a Rademacher sum]. Denote

\[
\tau^2(u,v) := \sum_{i=1}^{l'} \sum_{j=1}^r \phi_i^2(u) \left( \sum_{k=0}^{[l''/r]-1} \phi_{v+rk+j}(v) \right)^2.
\]

Observe that \( \tau^2(u,v) \leq \frac{l''}{r} q(l',u)q(l'',v) \leq q(l,u)q(l,v) \frac{1}{r} \), where \( q(l,u) := \sum_{j=1}^{l''} \phi_j^2(u), u \in V \), and we used the bound

\[
\left( \sum_{k=0}^{[l''/r]-1} \phi_{v+rk+j}(v) \right)^2 \leq \frac{l''}{r} \sum_{k=0}^{[l''/r]-1} \phi_{v+rk+j}(v).
\]

(2.6)

Thus, applying (2.3) to the Rademacher sum \( K'_\varepsilon \), we get

\[
\mathbb{E}|K_\varepsilon(u,v)|^p \leq 2^{p-1}(\mathbb{E}|K'_\varepsilon(u,v)|^p) + \mathbb{E}|K'_\varepsilon(v,u)|^p
\]

\[
\leq 2^p(p-1)^{p/2} \kappa^p (\tau^2(u,v) \vee \tau^2(v,u))^{p/2}
\]

\[
\leq 2^p(p-1)^{p/2} \kappa^p q^{p/2}(l,u)q^{p/2}(l,v) \left( \frac{1}{r} \right)^{p/2}.
\]

Given $p \in [2, +\infty]$, denote $Q_p(l) := \|P p(\cdot, \cdot)\|_{L_p(\Pi)} = \|1/2 \sum_{j=1}^t \varphi_j \|_{L_p(\Pi)}$ for $l = 1, \ldots, m$. This yields

$$E|K_c(X, X')|^p = E\langle K_c(X, X')^p | X, X' \rangle$$

$$\leq 2^p(p - 1)^{p/2}K^p \left( \frac{l}{r} \right)^{p/2} \left( \frac{E(q^{p/2}(l, X)q^{p/2}(l, X'))}{E\langle q^{p/2}(l, X) \rangle^2} \right)^{p/2}$$

$$= 2^p(p - 1)^{p/2}K^p \left( \frac{l}{r} \right)^{p/2} \left( \frac{1}{m} \right)^p Q_p(l).$$

Substituting the last bound into (2.5), we get

$$\mathbb{P}\{\xi \geq a\} \leq \frac{m^2E|K_c(X, X')|^p}{a^p} \leq m^22^p(p - 1)^{p/2}K^p \left( \frac{1}{r} \right)^{p/2} \left( \frac{1}{m} \right)^p Q_p(l).$$

Now, to get $\mathbb{P}\{\xi \geq a\} \leq 1/4$, it is enough to take

$$\kappa \leq 2^{-(1+2/p)}(p - 1)^{-1/2} \frac{1}{Q_p(l)} \frac{m a \sqrt{r}}{l} \frac{1}{\sqrt{t}} \frac{1}{m^2 \sqrt{p}}.$$

Next observe that

$$\text{card}(\Lambda) \geq \frac{3}{4} 2^{l/2} > \sum_{k=0}^{\lfloor l/2 \rfloor} \left( \frac{l}{k} \right).$$

It follows from Sauer’s lemma that there exists a subset $J \subset \{(i, j) : 1 \leq i \leq l', 1 \leq j \leq r\}$ with $\text{card}(J) = \lfloor l'/2 \rfloor + 1$ and such that $\pi_J(\Lambda) = \{-1, 1\}^J$, where $\pi_J:\{-1, 1\}^{l' \times r} \mapsto \{-1, 1\}^J$, $\pi_J(\sigma_{ij} : i = 1, \ldots, l', j = 1, \ldots, r) = (\sigma_{ij} : (i, j) \in J)$. Since $l \geq 32$, we have $l' \geq 16$ and $\text{card}(J) \geq 8$. We can now apply Varshamov–Gilbert bound to the combinatorial cube $\{-1, 1\}^J$ to prove that there exists a subset $E \subset \{-1, 1\}^J$ such that $\text{card}(E) \geq 2^{l'/2} + 1$ and, for all $\sigma', \sigma'' \in E, \sigma' \neq \sigma''$, $\sum_{(i, j) \in J} I(\sigma'_{ij} \neq \sigma''_{ij}) \geq \frac{l'}{16}$. It is now possible to choose a subset $\Lambda'$ of $\Lambda$ such that $\text{card}(\Lambda') = \text{card}(E)$ and $\pi_J(\Lambda') = E$. Then, we have $\text{card}(\Lambda') \geq 2^{l'/2} + 1$ and

$$\sum_{i=1}^{l'} \sum_{j=1}^r I(\sigma'_{ij} \neq \sigma''_{ij}) \geq \frac{l'}{16}$$

for all $\sigma', \sigma'' \in \Lambda', \sigma' \neq \sigma''$.

We are now in a position to define the set of distributions $\mathcal{P}$. For $\sigma \in \Lambda'$, denote by $P_\sigma$ the distribution of $(X, X', Y)$ such that $(X, X')$ is uniform in $V \times V$ and the conditional distribution of $Y$ given $(X, X')$ is defined as
follows:
\[ \mathbb{P}_{P_{\sigma}} \{ Y = \delta a | X, X' \} = p_{\sigma}(X, X') = 1/2 + \delta K_{\sigma}(X, X')/8a, \quad \delta \in \{ -1, +1 \}. \]

Since \(|K_{\sigma}(X, X')| \leq a\) for all \(\sigma \in \Lambda'\), we have \(p_{\sigma}(X, X') \in [3/8, 5/8], \sigma \in \Lambda\). Denote \(\mathcal{P} := \{ P_{\sigma} : \sigma \in \Lambda' \}\). For \(P = P_{\sigma} \in \mathcal{P}\), we have
\[ S_{P}(u, v) = \mathbb{E}(Y | X = u, X' = v) = \frac{1}{\sigma} K_{\sigma}(u, v). \]

Note that \(\text{rank}(S_{P}) = \text{rank}(K_{\sigma}) = \text{rank}(R_{\sigma} \otimes ) \leq r\); see the definitions of \(K_{\sigma}\) and \(R_{\sigma} \otimes \). Moreover, we have
\[ \|W_{1/2}K_{\sigma}\|_{L_{2}(\Pi^{2})}^{2} = \|W_{1/2} \sum_{i,j=1}^{m}(R_{\sigma} \otimes )_{ij}(\phi_{i} \otimes \phi_{j})\|_{L_{2}(\Pi^{2})}^{2} = \sum_{i,j=1}^{l} \lambda_{1}(R_{\sigma} \otimes )_{ij}^{2} \leq \lambda_{l}\|K_{\sigma}\|_{L_{2}(\Pi^{2})}^{2} \]
and
\[ \|K_{\sigma}\|_{L_{2}(\Pi^{2})}^{2} = \left\| \kappa \sum_{i=1}^{l'} \sum_{j=1}^{r} \sum_{k=0}^{[r'/r] - 1} \phi_{i} \otimes \phi_{i + \frac{r}{r}k + j} \right\|_{L_{2}(\Pi^{2})}^{2} + \kappa \sum_{i=1}^{l'} \sum_{j=1}^{r} \sum_{k=0}^{[r'/r] - 1} \phi_{i + \frac{r}{r}k + i} \otimes \phi_{j} \right\|_{L_{2}(\Pi^{2})}^{2} \]
\[ \leq 2\kappa^{2}l'r'[r'/r] \leq \kappa^{2}l'. \]
Therefore, \(\|W_{1/2}K_{\sigma}\|_{L_{2}(\Pi^{2})}^{2} \leq \lambda_{l}\kappa^{2}l'/r \), so, we have
\[ \|W_{1/2}S_{P_{\sigma}}\|_{L_{2}(\Pi^{2})} = \frac{1}{\lambda_{l}} \|W_{1/2}K_{\sigma}\|_{L_{2}(\Pi^{2})} \leq \rho^{2}, \]
provided that
\[ \kappa \leq \frac{m}{l} \frac{4\rho}{\sqrt{\lambda_{l}}}. \]
We can conclude that, for all \(P \in \mathcal{P}, S_{P} \in \mathcal{S}_{r, \rho}\) provided that \(\kappa\) satisfies conditions (2.7) and (2.10). Since also \(|Y| \leq a\), we have that \(\mathcal{P} \subset \mathcal{P}_{r, \rho, a}\).

Next we check that \(\mathcal{P}\) satisfies the conditions of Proposition 1. It is easy to see that, for all \(\sigma, \sigma' \in \Lambda' P_{\sigma} \ll P_{\sigma} \) and
\[ K(P_{\sigma} \| P_{\sigma'}) \]
\[ = \mathbb{E} \left( p_{\sigma}(X, X') \log \frac{p_{\sigma}(X, X')}{p_{\sigma'}(X, X')} + (1 - p_{\sigma}(X, X')) \log \frac{1 - p_{\sigma}(X, X')} {1 - p_{\sigma'}(X, X')} \right). \]
Using the elementary inequality \(- \log(1 + u) \leq -u + u^{2}, |u| \leq 1/2\) and the fact that \(p_{\sigma}(X, X') \in [3/8, 5/8], \sigma \in \Lambda\), we get that
\[ K(P_{\sigma} \| P_{\sigma'}) \leq \frac{6}{8a^{2}} \|K_{\sigma} - K_{\sigma'}\|_{L_{2}(\Pi^{2})} \leq \frac{1}{10a^{2}m^{2}} \|K_{\sigma} - K_{\sigma'}\|_{L_{2}(\Pi^{2})}^{2}, \quad \sigma' \in \Lambda'. \]
A simple computation based on the definition of \( K_\sigma, K_{\sigma'} \) easily yields that
\[
\|K_\sigma - K_{\sigma'}\|_2^2 \leq 8\kappa^2 l'r'[l''/r] \leq 8\kappa^2 l'l'' \leq 4\kappa^2 l^2.
\]

Thus, for the \( n \)-fold product-measures \( P^\otimes_\sigma, P^\otimes_{\sigma'} \), we get
\[
K(P^\otimes_\sigma||P^\otimes_{\sigma'}) = nK(P_\sigma||P_{\sigma'}) \leq \frac{4n\kappa^2 l^2}{10a^2 m^2}.
\]

For a fixed \( \sigma \in \Lambda' \), this yields
\[
\frac{1}{\text{card}(\Lambda') - 1} \sum_{\sigma' \in \Lambda'} K(P^\otimes_{\sigma'} || P^\otimes_{\sigma'}) \leq \frac{4n\kappa^2 l^2}{10a^2 m^2} \leq \frac{1}{10} \frac{l'r}{16}
\]
\[
\leq \frac{1}{10} \log(\text{card}(\Lambda') - 1),
\]
provided that
\[
\kappa \leq \frac{1}{16} \frac{m}{a} \frac{l}{r} \sqrt{\frac{l}{n}}.
\]

It remains to use (2.8) and the definition of kernels \( K_\sigma \) to bound from below the squared distance \( \|K_\sigma - K_{\sigma'}\|_{L^2(\Pi^2)}^2 \) for \( \sigma, \sigma' \in \Lambda', \sigma \neq \sigma' \),
\[
\|K_\sigma - K_{\sigma'}\|_{L^2(\Pi^2)}^2 = m^{-2} \|K_\sigma - K_{\sigma'}\|_2^2 \geq 4m^{-2}\kappa^2 l'r'[l''/r] \geq \frac{1}{64} \kappa^2 l^2.
\]

Since \( S_{P_\sigma} = \frac{1}{4} K_\sigma \), this implies that
\[
\|S_{P_\sigma} - S_{P'}\|_{L^2(\Pi^2)}^2 \geq 2^{-10} \kappa^2 l^2 m^2, \quad P, P' \in \mathcal{P}, P \neq P'.
\]

In view of (2.7), (2.12) and (2.10), we now take
\[
\kappa := \frac{1}{16} \frac{m}{l} \frac{4\rho}{l} \frac{1}{\sqrt{\lambda_l}} 2^{-(1+2/p)}(p-1)^{-1/2} \frac{1}{Q_p(l)} \frac{m}{l} \frac{1}{\sqrt{m}^2}.
\]

With this choice of \( \kappa \), \( \mathcal{P} := \{P_\sigma : \sigma \in \Lambda' \} \subset \mathcal{P}_{r,a,\rho} \). In view of (2.13) and (2.11), we can use Proposition 1 to get
\[
\inf_{S} \sup_{P \in \mathcal{P}_{r,a,\rho}} \mathbb{P}_P \{ \|\hat{S} - S_P\|_{L^2(\Pi^2)}^2 \geq c_1 \delta_n \}
\]
\[
\geq \inf_{S} \sup_{P \in \mathcal{P}} \mathbb{P}_P \{ \|\hat{S} - S_P\|_{L^2(\Pi^2)}^2 \geq c_1 \delta_n \} \geq c_2,
\]

where \( \delta_n := \frac{a^2 l^2}{n} \wedge \frac{b^2}{\lambda_l} \wedge \frac{1}{p-1} \frac{1}{Q^2_p(l)} \frac{a^2}{l^3} \frac{1}{m^3} \) and \( c_1, c_2 > 0 \) are constants.

In the case when \( r > l'' \), bound (2.14) still holds with
\[
\delta_n := \frac{a^2 l^2}{n} \wedge \frac{b^2}{\lambda_l} \wedge \frac{1}{p-1} \frac{1}{Q^2_p(l)} \frac{a^2}{m^4}.
\]
The proof is an easy modification of the argument in the case when \( r \leq l'' \). For \( r > l'' \), the construction becomes simpler: namely, we define

\[
R^p := \begin{pmatrix}
O_{\nu',\nu'} & R & O_{\nu',m-l} \\
R^T & O_{\nu',\nu'} & O_{\nu',m-l} \\
O_{m-l,\nu'} & O_{m-l,\nu'} & O_{m-l,m-l}
\end{pmatrix},
\]

where \( R \in \mathcal{R}_{\nu',\nu'} \), and, based on this, redefine kernels \( K_{\sigma}, \sigma \in \{-1,1\}^{l''} \times l'' \). The proof then goes through with minor simplifications.

Thus, in both cases \( r > l'' \) and \( r \leq l'' \), (2.14) holds with

\[
\delta_n = \delta_n(l) := \frac{a^2(r \wedge l)l}{n} \wedge \frac{\rho^2}{\lambda} \wedge \frac{1}{p-1} \frac{1}{Q_p^2(l)} \frac{a^2(r \wedge l)}{l} \frac{1}{m^{4/p}}.
\]

This is true under the assumption that \( l \geq 32 \). Note also that \( Q_p(l) \leq \max_{1 \leq j \leq m} \| \phi_j \|_{L_p}^2 = Q_p. \) Thus, we can replace \( Q_p^2(l) \) by the upper bound \( Q_p^2 \) in the definition of \( \delta_n(l) \).

We can now choose \( l \in \{32, \ldots, m\} \) that maximizes \( \delta_n(l) \) to get bound (2.14) with \( \delta_n := \min_{32 \leq l \leq m} \delta_n(l) \). This completes the proof in the case when \( k_0 \geq 32 \) and \( l_0 = 32 \). If \( k_0 < 32 \), it is easy to use the condition \( \lambda_{l+1} \leq c\lambda_l, l \geq k_0 \) and to show that \( \min_{32 \leq l \leq m} \delta_n(l) \leq c' \min_{k_0 \leq l \leq m} \delta_n(l) \), where \( c' \) is a constant depending only on \( c \). This completes the proof in the remaining case. \( \square \)

**Proof of Theorem 3.** The only modification of the previous proof is to replace bound (2.6) by \((\sum_{k=0}^{[\nu'/p]-1} \phi_{\nu'+rk+j}(v))^2 \leq d \sum_{k=0}^{[\nu'/p]-1} \phi_{\nu'+rk+j}(v)^2 \) Then, the outcome of the next several lines of the proof is that \( \mathbb{P}\{ \xi \geq a \} \leq 1/4 \) provided that [instead of (2.7)]

\[
\kappa \leq 2^{-(1+2/p)}(p-1)^{-1/2} \frac{1}{Q_p(l)} \frac{m}{a} \frac{1}{l} \frac{1}{\sqrt{d} m^{2/p}}.
\]

As a result, at the end of the proof, we get that (2.14) holds with

\[
\delta_n = \delta_n(l) := \frac{a^2(r \wedge l)l}{n} \wedge \frac{\rho^2}{\lambda} \wedge \frac{1}{p-1} \frac{1}{Q_p^2(l)} \frac{a^2}{d} \frac{1}{m^{4/p}}.
\]

It remains to observe that \( Q_p(l) \leq \frac{m}{T} \), which follows from the fact that

\[
\sum_{j=1}^{l} \phi_j^2(v) = \sum_{j=1}^{l} \langle \phi_j, e_v \rangle^2 \leq \sum_{j=1}^{m} \langle \phi_j, e_v \rangle^2 = 1, \quad v \in V,
\]

and to take \( p = \log m \) to complete the proof. \( \square \)
3. Least squares estimators with nonconvex penalties. In this section, we derive upper bounds on the squared $L_2(\Pi^2)$-error of the following least squares estimator of the target matrix $S_*$:

\[(3.1) \quad \hat{S}_l := \hat{S}_{r,l,a} := \arg\min_{S \in \mathcal{S}_r(l;a)} \frac{1}{n} \sum_{j=1}^{n} (Y_j - S(X_j, X'_j))^2,\]

where $\mathcal{S}_r(l;a) := \{ S^a : S \in \mathcal{S}_r(l;a) \}, l = 1, \ldots, m$,

\[\mathcal{S}_r(l;a) := \left\{ S : S \in \mathcal{S}_V, \text{rank}(S) \leq r, \|S\|_{L_2(\Pi^2)} \leq a, S = \sum_{i,j=1}^{l} s_{ij}(\phi_i \otimes \phi_j) \right\}.\]

Here $S^a$ denotes a truncation of kernel $S : S^a(u,v) = S(u,v)$ if $|S(u,v)| \leq a$, $S^a(u,v) = a$ if $S(u,v) > a$ and $S^a(u,v) = -a$ if $S(u,v) < -a$. Note that the kernels in the class $\mathcal{S}_r(l;a)$ are symmetric and $\text{rank}(S) \leq r \land l$, $S \in \mathcal{S}_r(l;a)$. Note also that the sets $\mathcal{S}_r(l;a), \hat{S}_r(l;a)$ and optimization problem (3.1) are not convex. We will prove the following result under the assumption that $|Y| \leq a$ a.s. Recall the definition of the class of kernels $\mathcal{S}_{r,\rho}$ in Section 2.

**Theorem 4.** There exist constants $C > 0, A > 0$ such that, for all $t > 0$, with probability at least $1 - e^{-t}$,

\[(3.2) \quad \|\hat{S}_l - S_*\|_{L_2(\Pi^2)}^2 \leq 2 \inf_{S \in \mathcal{S}_r(l;a)} \|S - S_*\|_{L_2(\Pi^2)}^2 + C \left( \frac{a^2 (r \land l) l}{n} \log \left( \frac{Anm}{(r \land l)l} \right) + \frac{a^2 t}{n} \right).\]

In particular, for some constants $C, A > 0$, for $S_* \in \mathcal{S}_r,\rho$ and for all $t > 0$, with probability at least $1 - e^{-t}$,

\[(3.3) \quad \|\hat{S}_l - S_*\|_{L_2(\Pi^2)}^2 \leq C \left[ \frac{a^2 (r \land l) l}{n} \log \left( \frac{Anm}{(r \land l)l} \right) \lor \frac{\rho^2}{\lambda l+1} \lor \frac{a^2 t}{n} \right].\]

**Proof.** Without loss of generality, assume that $a = 1$; this would imply the general case by a simple rescaling of the problem. We will use a version of well-known bounds for least squares estimators over uniformly bounded function classes in terms of Rademacher complexities. Specifically, consider the following least squares estimator: $\hat{g} := \arg\min_{g \in \mathcal{G}} n^{-1} \sum_{j=1}^{n} (Y_j - g(X_j))^2$, where $(X_1, Y_1), \ldots, (X_n, Y_n)$ are i.i.d. copies of a random couple $(X, Y)$ in $T \times \mathbb{R}$, $(T, \mathcal{T})$ being a measurable space, $|Y| \leq 1$ a.s., $\mathcal{G}$ being a class of measurable functions on $T$ uniformly bounded by 1. The goal is to estimate the regression function $g_+(x) := \mathbb{E}(Y|X = x)$. Define localized Rademacher complexity $\psi_n(\delta) := \mathbb{E}\sup_{g_1, g_2 \in \mathcal{G}, \|g_1 - g_2\|_{L_2(\Pi)}^2 \leq \delta} |R_n(g_1 - g_2)|$, where $\Pi$ is the distribution of $X$ and $R_n(g) := n^{-1} \sum_{j=1}^{n} \varepsilon_j g(X_j)$ is the Rademacher process,
{\varepsilon_j} being a sequence of i.i.d. Rademacher random variables independent of 
{X_j}. Denote \(\psi_n^\varepsilon(\delta) := \sup_{\|\sigma\|_\infty \geq \delta} \frac{\psi_n(\sigma)}{\sigma}\) and \(\psi_n^\varepsilon(\varepsilon) := \inf \{\delta > 0 : \psi_n^\varepsilon(\delta) \leq \varepsilon\}\). The 
next result easily follows from Theorem 5.2 in [9]:

**Proposition 2.** There exist constants \(c_1, c_2 > 0\) such that, for all \(t > 0\), 
with probability at least \(1 - e^{-t}\),

\[
\|\hat{g} - g_s\|_2^2 \leq 2 \inf_{g \in G} \|g - g_s\|_2^2 + c_1 \left( \psi_n^\varepsilon(c_2) + \frac{t}{n} \right).
\]

We will apply this proposition to prove Theorem 4. In what follows in the 
proof, denote \(\tilde{S} := \tilde{S}_l\). In our case, \(T = V \times V\), \((X, X')\) plays the role of \(X\), 
and \(\Pi'\) plays the role of \(\Pi\). Let \(G := \tilde{S}_{r,l;1}\), \(g_s = S_s\) and \(\hat{g} = \tilde{S}\). First, we 
need to upper bound the Rademacher complexity \(\psi_n(\delta)\) for the class \(G\). Let \(S_{r,m}(R)\) be the set of all symmetric \(m \times m\) matrices \(S\) with \(\text{rank}(S) \leq r\) and 
\(\|S\|_2 \leq R\). The \(\varepsilon\)-covering number \(N(S_{r,m}(R); \|\cdot\|_2; \varepsilon)\) of the set \(S_{r,m}(R)\) 
with respect to the Hilbert–Schmidt distance (i.e., the minimal number of 
balls of radius \(\varepsilon\) needed to cover this set) can be bounded as follows:

\[
N(S_{r,m}(R); \|\cdot\|_2; \varepsilon) \leq \left( \frac{18R}{\varepsilon} \right)^{(m+1)r}.
\]

Such bounds are well known (see, e.g., [9], Lemma 9.3 and references therein; 
the proof of this lemma can be easily modified to obtain (3.4)). Bound 
(3.4) will be used to control the covering numbers of the set of kernels 
\(S_{r,l;1}\). This set can be easily identified with a subset of the set \(S_{r \wedge l;1}(m)\) 
since kernels \(S \in S_{r,l;1}\) can be viewed as symmetric \(l \times l\) matrices of 
rank at most \(r \wedge l\) with \(\|S\|_2 \leq 1\) and \(\|S\|_2 \leq m\|S\|_2 \leq m\) [m]. Therefore, we get the following bound: \(N(S_{r,l;1}; \|\cdot\|_2; \varepsilon) \leq \left( \frac{18m}{\varepsilon} \right)^{(l+1)(r \wedge l)}\). Since 
\(\|S^1_l - S^2_l\|_2^2 \leq \|S_1 - S_2\|_2^2\) (truncation of the entries reduces the 
Hilbert–Schmidt distance), we also have \(N(S_{r,l;1}; \|\cdot\|_2; \varepsilon) \leq \left( \frac{18m}{\varepsilon} \right)^{(l+1)(r \wedge l)}\). Since 
\(\|E_{X_j'X_j}\|_2 \leq 1\), \(\|S_1 - S_2\|_2^2 = \frac{1}{n} \sum_{j=1}^n (S_1 - S_2, E_{X_j'X_j})^2 \leq \|S_1 - S_2\|_2^2\). Therefore, we get the following bound on the \(L_2(\Pi_n)\)-covering numbers 
of the set \(S_{r,l;1} N(S_{r,l;1} L_2(\Pi_n); \varepsilon) \leq \left( \frac{18m}{\varepsilon} \right)^{(l+1)(r \wedge l)}\). Here \(\Pi_n\) denotes the 
empirical distribution based on observations \((X_1, X'_1), \ldots, (X_n, X'_n)\). The 
last bound allows us to use inequality (3.17) in [9] to control the localized 
Rademacher complexity \(\psi_n(\delta)\) of the class \(G\) as follows:

\[
\psi_n(\delta) = \mathbb{E} \sup_{S_1, S_2 \in S_{r,l;1}, \|S_1 - S_2\|_2^2 \leq \delta} \left| n^{-1} \sum_{j=1}^n \varepsilon_j (S_1(X_j, X'_j) - S_2(X_j, X'_j)) \right|
\]

\[
\leq C_1 \left[ \sqrt{\frac{\delta l (r \wedge l)}{n}} \log \left( \frac{Am}{\sqrt{\delta}} \right) \vee \frac{l (r \wedge l)}{n} \log \left( \frac{Am}{\sqrt{\delta}} \right) \right].
\]
with some constant $A,C_1 > 0$. This easily yields $\psi_n^2(c_2) \leq C_2 \frac{\log(mn)}{m}$ with some constants $A,C_2 > 0$. Proposition 2 now implies bound (3.2).

To prove bound (3.3), it is enough to observe that, for $S_* \in S_r, \rho$,

\begin{equation}
\inf_{S \in S_r(l;1)} \|S - S_*\|_{L_2(\mathbb{P}^2)}^2 \leq \frac{2\rho^2}{\lambda_{l+1}}.
\end{equation}

Indeed, since $S_* \in S_r, \rho$, we can approximate this kernel by $S_l := \sum_{i,j=1}^l (S_* \phi_i, \phi_j)(\phi_i \otimes \phi_j)$. For the error of this approximation, we have

\[
\|S_l - S_*\|_{L_2(\mathbb{P}^2)}^2 = m^{-2} \|S_l - S_*\|_2^2 = m^{-2} \sum_{i,j>l} (S_* \phi_i, \phi_j)^2
\]

\[
\leq m^{-2} \frac{1}{\lambda_{l+1}} \sum_{i,j=1}^m \lambda_i (S_* \phi_i, \phi_j)^2 + m^{-2} \frac{1}{\lambda_{l+1}} \sum_{i=1}^m \sum_{j>l} \lambda_j (S_* \phi_i, \phi_j)^2 \leq \frac{2\rho^2}{\lambda_{l+1}},
\]

which implies $\|S_l^1 - S_*\|_{L_2(\mathbb{P}^2)}^2 \leq \|S_l - S_*\|_{L_2(\mathbb{P}^2)}^2 \leq \frac{2\rho^2}{\lambda_{l+1}}$ (since the entries of matrix $S_*$ are bounded by 1 and truncation of the entries reduces the Hilbert–Schmidt distance). We also have rank($S_l$) $\leq$ rank($S_*$) $\leq r$ and

\[
\|S_l\|_{L_2(\mathbb{P}^2)} = m^{-1}\|S_l\|_2 \leq m^{-1}\|S_*\|_2 = \|S_*\|_{L_2(\mathbb{P}^2)} \leq \|S_*\|_{L_\infty} \leq 1.
\]

Therefore, $S_l^1 \in S_r(l;1)$ and bound (3.6) follows. Bound (3.3) is a consequence of (3.2) and (3.6).

Remark. Note that, in the case when the basis of eigenfunctions $\{\phi_j\}$ coincides with the canonical basis of space $\mathbb{R}^V$, the following bound holds trivially:

\begin{equation}
\|\hat{S}_l - S_*\|_{L_2(\mathbb{P}^2)}^2 \leq \frac{4a^2l^2r \log(mn)}{m^2} + \frac{2\rho^2}{\lambda_{l+1}}.
\end{equation}

This follows from the fact that the entries of both matrices $\hat{S}_l$ and $S_l$ are bounded by $a$, and their nonzero entries are only in the first $l$ rows and the first $l$ columns, so, $\|\hat{S}_l - S_l\|_{L_2(\mathbb{P}^2)}^2 \leq \frac{4a^2l^2r \log(mn)}{m^2}$. Combining this with (3.3) and minimizing the resulting bound with respect to $l$ yields the following upper bound (up to a constant) that holds for the optimal choice of $l$:

\[
\min_{1 \leq l \leq m} \left[ \frac{a^2(r \land l)}{n} \log \left( \frac{Anm}{(r \land l)l} \right) \wedge \frac{a^2l^2}{m^2} \right] \wedge \frac{\rho^2}{\lambda_{l+1}} \wedge \frac{\rho^2}{n}.
\]

It is not hard to check that, typically, this expression is of the same order (up to log factors) as the lower bound of Theorem 3 for $d = 1$.

Next we consider a penalized version of least squares estimator which is adaptive to unknown parameters of the problem (such as the rank of the target matrix and the optimal value of parameter $l$ which minimizes the
error bound of Theorem 4). We still assume that $|Y| \leq a$ a.s. for some known constant $a > 0$. Define

$$
(\hat{r}, \hat{l}) := \arg\min_{r,l=1,\ldots,m} \left\{ n^{-1} \sum_{j=1}^{n} (Y_j - \hat{S}_{r,l,a}(X_j, X_j'))^2 + K \frac{a^2(r \wedge l)l}{n} \log \left( \frac{Amn}{(r \wedge l)l} \right) \right\}
$$

(3.8)

and let $\hat{S} := \hat{S}_{\hat{r},\hat{l},a}$. Here $K > 0$ and $A > 0$ are fixed constants.

The following theorem provides an oracle inequality for the estimator $\hat{S}$.

**Theorem 5.** There exists a choice of constants $K > 0$, $A > 0$ in (3.8) and $C > 0$ in the inequality below such that for all $t > 0$ with probability at least $1 - e^{-t}$

$$
\|\hat{S} - S_*\|_{L_2(\Pi^2)}^2 \leq 2 \min_{1 \leq r \leq m, 1 \leq l \leq m} \left[ \inf_{S \in \hat{S}_{r,l,a}} \|S - S_*\|_{L_2(\Pi^2)}^2 + C \left( \frac{n^{-2}(r \wedge l)l}{n} \log \left( \frac{Amn}{(r \wedge l)l} \right) + \frac{n^{-2}(t + \log m)}{n} \right) \right].
$$

(3.9)

**Proof.** As in the proof of the previous theorem, we can assume that $a = 1$; the general case follows by rescaling. We will use oracle inequalities in abstract penalized empirical risk minimization problems; see [9], Theorem 6.5. We only sketch the proof here skipping the details that are standard. As in the proof of Theorem 4, first consider i.i.d. copies $(X_1, Y_1), \ldots, (X_n, Y_n)$ of a random couple $(X, Y)$ in $T \times \mathbb{R}$, where $(T, \mathcal{T})$ is a measurable space and $|Y| \leq 1$ a.s. Let $\{\hat{G}_k : k \in I\}$ be a finite family of classes of measurable functions from $T$ into $[-1, 1]$. Consider the corresponding family of least squares estimators $\hat{g}_k := \arg\min_{g \in \hat{G}_k} n^{-1} \sum_{j=1}^{n} (Y_j - g(X_j))^2$, $k \in I$. Suppose the following upper bounds on localized Rademacher complexities for classes $\hat{G}_k$, $k \in I$ hold: $\mathbb{E} \sup_{g_1, g_2 \in \hat{G}_k, \|g_1 - g_2\|_{L_2(\Pi)} \leq \delta} |R_n(g_1 - g_2)| \leq \psi_{n,k}(\delta)$, $\delta > 0$, where $\psi_{n,k}$ are nondecreasing functions of $\delta$ that do not depend on the distribution of $(X, Y)$. Let

$$
\hat{k} := \arg\min_{k \in I} \left[ n^{-1} \sum_{j=1}^{n} (Y_j - \hat{g}_k(X_j))^2 + K \psi_{n,k}^2(c_1) + \frac{t_k}{n} \right],
$$

(3.10)

and $K, c_1$ are constants and $\{t_k, k \in I\}$ are positive numbers. Define the following penalized least squares estimator of the regression function $g_* : \hat{g} := \hat{g}_{\hat{k}}$.

The next result is well known; it can be deduced, for instance, from Theorem 6.5 in [9].
Proposition 3. There exists constants $K, c_1 > 0$ in the definition (3.10) of $k$ and a constant $K_1 > 0$ such that, for all $t_k > 0$, with probability at least $1 - \sum_{k \in I} e^{-t_k}$

$$\|\hat{g} - g^*\|^2_{L_2(\Pi)} \leq 2 \inf_{k \in I} \left[ \inf_{g \in G_k} \|g - g^*\|^2_{L_2(\Pi)} + K_1 \left( \psi_{n,k}^2(c) + \frac{t_k}{n} \right) \right].$$

We apply this result to the estimator $\hat{S} = \hat{S}_{\hat{r}, \hat{l}, 1}$, where $(\hat{r}, \hat{l})$ is defined by (3.8) (with $a = 1$). In this case, $T = V \times V', (X, X')$ plays the role of $X$, $g^* = S^*$, $I = \{(r, l): r, l \leq m\}$, $G_{r,l} = \hat{S}_{r,l}(l; 1)$. In view of (3.5), we can use the following bounds on localized Rademacher complexities for these function classes:

$$\psi_{n,r,l}(\delta) := C_1 \left[ \sqrt{\Delta(r \wedge l)} \sqrt{\log \left( \frac{Am}{\sqrt{\delta}} \right)} \right]$$

with some constant $C_1$, and we have $\psi_{n,r,l}(c_1) \leq C_2 \left( \frac{r \wedge l}{\Delta(r \wedge l)} \right) \log \left( \frac{Am}{\Delta(r \wedge l)} \right)$ with some constant $C_2 > 0$. Define $t_{r,l} := t + 2 \log m, (r, l) \in I$. This yields the bound $\sum_{(r, l) \in I} e^{-t_{r,l}} \leq e^{-t}$. These considerations and Proposition 3 imply the claim of the theorem. \(\Box\)

It follows from Theorem 5 that, for some constant $C > 0$ and for all $t > 0$,

$$\sup_{P \in \mathcal{P}_{r, \rho, a}} \mathbb{P}_P \left\{ \|\hat{S} - S_P\|^2_{L_2(\Pi^2)} \geq C \left( \Delta_n(r, \rho, a) \vee \frac{a^2 t}{n} \right) \right\} \leq e^{-t},$$

where $\Delta_n(r, \rho, a) := \min_{1 \leq t \leq m} \left[ \frac{a^2 (r \wedge l) \log \left( \frac{Am}{\Delta(r \wedge l)} \right)}{n} \right] \vee \frac{a^2}{\Delta_{t+1}}$. Denoting

$$\tilde{l} := \min \left\{ l = 1, \ldots, m : (r \wedge l) \log \left( \frac{Am}{(r \wedge l) l} \right) \geq \frac{\rho^2 \log(n)}{a^2} \right\},$$

it is easy to see that $\Delta_n(r, \rho, a) = \frac{a^2 \rho^{2/\beta} \tilde{l}}{n} \log \left( \frac{Am}{\tilde{l}} \right) \vee \frac{a^2}{\tilde{l}}$.

Example. Suppose that, for some $\beta > 1/2$, $\lambda_l \asymp l^{2\beta}, l = 1, \ldots, m$. Under this assumption, it is easy to show that the upper bound on the squared $L_2(\Pi^2)$-error of the estimator $\hat{S}$ is of the order

$$\left( \frac{a^2 \rho^{1/\beta} r}{n} \log \left( \frac{Am}{r} \right) \right)^{2\beta/(2\beta + 1)} \wedge \left( \frac{a^2 \rho^{2/\beta} \log(Anm)}{n} \right)^{\beta/\beta + 1} \wedge \frac{a^2 t}{n}$$

(in fact, the log factors can be written in a slightly better, but more complicated way). Up to the log factors, this is the same error rate as in the lower bounds of Section 2; see (2.1).
4. Least squares with convex penalization: Combining nuclear norm and squared Sobolev norm. Our main goal in this section is to study the following penalized least squares estimator with a combination of two convex penalties:

\[
\hat{S}_{\varepsilon,\bar{\varepsilon}} := \arg\min_{S \in \mathcal{D}} \left[ \frac{1}{n} \sum_{j=1}^{n} (Y_j - S(X_j, X_j'))^2 + \varepsilon \|S\|_1 + \bar{\varepsilon} \|W^{1/2}S\|_{L_2(\Pi^2)}^2 \right],
\]

where \(\mathcal{D} \subset \mathcal{S}_V\) is a closed convex set of symmetric kernels such that, for all \(S \in \mathcal{D}\), \(\|S\|_{L_\infty} := \max_{u,v \in V} |S(u, v)| \leq a\), and \(\varepsilon, \bar{\varepsilon} > 0\) are regularization parameters. The first penalty involved in (4.1) is based on the nuclear norm \(\|S\|_1\), and it is used to “promote” low-rank solutions. The second penalty is based on a “Sobolev type norm” \(\|W^{1/2}S\|_{L_2(\Pi^2)}^2\). It is used to “promote” the smoothness of the solution on the graph.

We will derive an upper bound on the error \(\|\hat{S}_{\varepsilon,\bar{\varepsilon}} - S_*\|_{L_2(\Pi^2)}^2\) of estimator \(\hat{S}_{\varepsilon,\bar{\varepsilon}}\) in terms of spectral characteristics of the target kernel \(S_*\) and matrix \(W\). As before, \(W\) is a nonnegative definite symmetric kernel with spectral representation \(W = \sum_{k=1}^{m} \lambda_k (\phi_k \otimes \phi_k)\), where \(0 \leq \lambda_1 \leq \cdots \leq \lambda_m\) are the eigenvalues of \(W\) repeated with their multiplicities and \(\phi_1, \ldots, \phi_m\) are the corresponding orthonormal eigenfunctions. We will also use the decomposition of identity associated with \(W\): \(E(\lambda) := \sum_{\lambda_j \leq \lambda} (\phi_j \otimes \phi_j), \lambda \geq 0\). Clearly, \(\lambda \mapsto E(\lambda)\) is a nondecreasing projector-valued function. Despite the fact that the eigenfunctions \(\{\phi_k\}\) are not uniquely defined in the case when \(W\) has multiple eigenvalues, the decomposition of identity \(\{E(\lambda), \lambda \geq 0\}\) is uniquely defined (in fact, it can be rewritten in terms of spectral projectors of \(W\)).

The distribution of the eigenvalues of \(W\) is characterized by the following spectral function:

\[F(\lambda) := \text{tr}(E(\lambda)) = \|E(\lambda)\|_2^2 = \sum_{j=1}^{m} I(\lambda_j \leq \lambda), \quad \lambda \geq 0.\]

Denote \(k_0 := F(0) + 1\) (in other words, \(k_0\) is the smallest \(k\) such that \(\lambda_k > 0\)). It was assumed in the Introduction that there exists a constant \(c \geq 1\) such that \(\lambda_{k+1} \leq c \lambda_k\) for all \(k \geq k_0\).

In what follows, we use a regularized majorant of spectral function \(F\). Let \(\bar{F} : \mathbb{R}_+ \mapsto \mathbb{R}_+\) be a nondecreasing function such that \(F(\lambda) \leq \bar{F}(\lambda), \lambda \geq 0\), the function \(\lambda \mapsto \frac{\bar{F}(\lambda)}{\lambda}\) is nonincreasing and, for some \(\gamma \in (0, 1)\),

\[
\int_{\lambda}^{\infty} \frac{\bar{F}(s)}{s^2} \, ds \leq \frac{1}{\gamma} \frac{\bar{F}(\lambda)}{\lambda}, \quad \lambda > 0.
\]

Without loss of generality, we assume in what follows that \(\bar{F}(\lambda) = m, \lambda \geq \lambda_m\) [otherwise, one can take the function \(\bar{F}(\lambda) \wedge m\) instead]. The conditions on \(\bar{F}\) are satisfied if for some \(\gamma \in (0, 1)\), the function \(\frac{\bar{F}(\lambda)}{\lambda^{\gamma - 1}}\) is nonincreasing; in
majorant for the coherence function \( \phi \) all nondecreasing functions \( m \sum S \) sional rank” of \( I \). It is immediate from this definition that \( \varphi = \varphi \psi \) (possibly repeated) and \( \phi \bar{S} \) contains the smallest function (uniformly in \( \lambda \)) that, for all \( \bar{S} \), \( \bar{S} \)−\( \geq 0 \).

Consider a kernel \( S \in \mathcal{S}_{V} \) (an oracle) with spectral representation: \( S = \sum_{k=1}^{r} \mu_{k} (\psi_{k} \otimes \psi_{k}) \), where \( r = \text{rank}(S) \geq 1 \), \( \mu_{k} \) are nonzero eigenvalues of \( S \) (possibly repeated) and \( \psi_{k} \) are the corresponding orthonormal eigenfunctions. Denote \( L = \text{supp}(S) = \text{l.s.}(\psi_{1}, \ldots, \psi_{r}) \). The following coherence function will be used to characterize the relationship between the kernels \( S \) and \( W \):

\[
\varphi(S; \lambda) := \langle P_{L}, E(\lambda) \rangle := \sum_{\lambda_{j} \leq \lambda} \| P_{L} \phi_{j} \|^{2}, \quad \lambda \geq 0.
\]

It is immediate from this definition that \( \varphi(S, \lambda) \leq F(\lambda) \leq \tilde{F}(\lambda), \lambda \geq 0 \). Note also that \( \varphi(S; \lambda) \) is a nondecreasing function of \( \lambda \) and \( \varphi(S, \lambda) = \sum_{j=1}^{m} \| P_{L} \phi_{j} \|^{2} = r, \lambda \geq \lambda_{m} \) [for \( \lambda < \lambda_{m}, \varphi(S; \lambda) \) can be interpreted as a “partial rank” of \( S \)]. As in the case of spectral function \( S \), we need a regularized majorant for the coherence function \( \varphi(S; \lambda) \). Denote by \( \Psi = \Psi_{S,W} \) the set of all nondecreasing functions \( \varphi : \mathbb{R}_{+} \mapsto \mathbb{R}_{+} \) such that \( \lambda \mapsto \frac{\varphi(\lambda)}{F(\lambda)} \) is nonincreasing and \( \varphi(S; \lambda) \leq \varphi(\lambda), \lambda \geq 0 \). It is easy to see that the class of functions \( \Psi_{S,W} \) contains the smallest function (uniformly in \( \lambda \geq 0 \)) that will be denoted by \( \tilde{\varphi}(S; \lambda) \) and it is given by the following expression:

\[
\tilde{\varphi}(S; \lambda) := \sup_{\sigma} \tilde{F}(\sigma) \sup_{\sigma' \geq \sigma} \frac{\varphi(S; \sigma')}{F(\sigma')}.
\]

It easily follows from this definition that \( \tilde{\varphi}(S, \lambda) = r, \lambda \geq \lambda_{m} \). Note that since the function \( \frac{\varphi(S, \lambda)}{F(\lambda)} \) is nonincreasing and it is equal to \( \frac{r}{m} \) for \( \lambda \geq \lambda_{m} \), we have

\[
\tilde{\varphi}(S; \lambda) \geq \frac{r}{m} \tilde{F}(\lambda) \geq \frac{r}{m} F(\lambda), \quad \lambda \geq 0.
\]

Given \( t > 0, \tilde{\lambda} \in (0, \lambda_{0}], \) let \( t_{n,m} := t + 3 \log(2 \log_{2} n + \frac{1}{2} \log_{2} \frac{\lambda_{m}}{\lambda} + 2) \). Suppose that, for some \( D > 0 \),

\[
\varepsilon \geq Da \left( \sqrt{\frac{\log(2m)}{nm}} + \frac{\log(2m)}{n} \right).
\]

**Theorem 6.** There exists constants \( C, D \) depending only on \( c, \gamma \) such that, for all \( \varepsilon \in [0, \lambda^{-1}] \) with probability at least \( 1 - e^{-t} \),

\[
\| \hat{S}_{\varepsilon, t} - S \|_{L_{2}(\Pi^{2})}^{2} \leq \inf_{S \in \mathcal{D}} \| S - S \|_{L_{2}(\Pi^{2})}^{2} + C m^{2} \varepsilon^{2} \tilde{\varphi}(S; \varepsilon^{-1}) + \varepsilon \| W^{1/2} S \|_{L_{2}(\Pi^{2})}^{2}
\]

\[
+ C a^{2} t_{n,m}.
\]
Remarks. (1) Under the additional assumption that $m \log(2m) \leq n$, one can take $\varepsilon = Da \sqrt{\frac{\log(2m)}{nm}}$. In this case, the main part of the random error term in the right-hand side of bound (4.5) becomes

$$Cm^2 \varepsilon^2 \tilde{\varphi}(S; \bar{\varepsilon}^{-1}) + \bar{\varepsilon} W^{1/2} S \|_{L_2(\Pi^2)}$$

$$= C'n^2 \bar{\varphi}(S; \bar{\varepsilon}^{-1}) \sqrt{\log(2m)} \|_{L_2(\Pi^2)} + \bar{\varepsilon} W^{1/2} S \|_{L_2(\Pi^2)}.$$

(2) Note also that Theorem 6 holds in the case when $\bar{\varepsilon} = 0$. In this case, our method coincides with nuclear norm penalized least squares (matrix LASSO) and $\tilde{\varphi}(S; \bar{\varepsilon}^{-1}) = \text{rank}(S)$, so the bound of Theorem 6 becomes

$$\| \hat{S}_{\varepsilon,0} - S_* \|_{L_2(\Pi^2)}^2 \leq \inf_{S \in \mathcal{D}} \| S - S_* \|_{L_2(\Pi^2)}^2 + Cm^2 \varepsilon^2 \text{rank}(S) + C \frac{a^2 t_{n,m}}{n}.$$

Similar oracle inequalities were proved in [10] for a linearized least squares method with nuclear norm penalty.

Using simple aggregation techniques, it is easy to construct an adaptive estimator for which the oracle inequality of Theorem 6 holds with the optimal value of $\bar{\varepsilon}$ that minimizes the right-hand side of the bound. To this end, divide the sample $(X_1, X'_1, Y_1), \ldots, (X_n, X'_n, Y_n)$ into two parts,

$$(X_j, X'_j, Y_j), \quad j = 1, \ldots, n'$$

and

$$(X_{n'+j}, X'_{n'+j}, Y_{n'+j}), \quad j = 1, \ldots, n - n',$$

where $n' := \lfloor n/2 \rfloor + 1$. The first part of the sample will be used to compute the estimators $\hat{S}_l := \hat{S}_{\varepsilon, \varepsilon_l}, \varepsilon_l := \chi_l^{-1}, l = k_0, \ldots, m + 1$ [they are defined by (4.1), but they are based only on the first $n'$ observations]. The second part of the sample is used for model selection

$$\hat{l} := \arg\min_{l = k_0, \ldots, m + 1} \frac{1}{n - n'} \sum_{j=1}^{n-n'} (Y_{n'+j} - \hat{S}_l(X_{n'+j}, X'_{n'+j}))^2.$$

Finally, let $\hat{S} := \hat{S}_{\hat{l}}$.

Theorem 7. Under the assumptions and notation of Theorem 6, with probability at least $1 - e^{-t}$,

$$\| \hat{S} - S_* \|_{L_2(\Pi^2)}^2 \leq \inf_{S \in \mathcal{D}} \left[ 2 \| S - S_* \|_{L_2(\Pi^2)}^2 + C \inf_{\varepsilon \in [0, \lambda^{-1}_{k_0}]} (m^2 \varepsilon^2 \tilde{\varphi}(S; \bar{\varepsilon}^{-1}) + \bar{\varepsilon} W^{1/2} S \|_{L_2(\Pi^2)}^2) \right]$$

$$+ C \frac{a^2 (\log(m + 1) + t_{n,m})}{n}.$$
Proof. The idea of aggregation result behind this theorem is rather well known; see [12], Chapter 8. The proof can be deduced, for instance, from Proposition 2 used in Section 3. Specifically, this proposition has to be applied in the case when $\mathcal{G}$ is a finite class of functions bounded by 1. Let $N := \text{card}(\mathcal{G})$. Then, for some numerical constant $C_1 > 0$

$$\psi_n(\delta) \leq C_1 \left[ \delta \sqrt{\frac{\log N}{n}} + \frac{\log N}{n} \right]$$

(see, e.g., [9], Theorem 3.5), and Proposition 2 easily implies that, for all $t > 0$, with probability at least $1 - e^{-t}$

$$\| \hat{g} - g_* \|_{L_2(\Pi)}^2 \leq 2 \inf_{g \in \mathcal{G}} \| g - g_* \|_{L_2(\Pi)}^2 + C_2 \frac{\log N + t}{n}, \tag{4.8}$$

where $C_2 > 0$ is a constant. We will assume that $a = 1$ (in the general case, the result would follow by rescaling) and use bound (4.8), conditionally on the first part of the sample, in the case when $\mathcal{G} := \{ \hat{g}_l : l = k_0, \ldots, m + 1 \}$. Then, given $(X_j, X_j^*, Y_j^*), j = 1, \ldots, n'$, with probability at least $1 - e^{-t}$,

$$\| \hat{S} - S_* \|_{L_2(\Pi)}^2 \leq 2 \min_{k_0 \leq l \leq m + 1} \| \hat{S}_l - S_* \|_{L_2(\Pi)}^2 + C_2 \frac{\log (m + 1) + t}{n}. \tag{4.9}$$

By Theorem 6 [with $t$ replaced by $t + \log(m + 1)$] and the union bound, we get that, with probability at least $1 - e^{-t}$, for all $l = k_0, \ldots, m + 1$,

$$\| \hat{S}_l - S_* \|_{L_2(\Pi)}^2 \leq \inf_{S \in \mathbb{D}} \left[ | | S - S_* | |_{L_2(\Pi)}^2 + C_3 m^2 \varepsilon^2 \varphi(S; \varepsilon_l^{-1}) + \varepsilon_l | | W^{1/2} S | |_{L_2(\Pi)}^2 \right] + C_3 \frac{\log (m + 1) + t_{n,m}}{n} \tag{4.10}$$

with some constant $C_3 > 0$. Therefore, the minimal error of estimators $\hat{S}_l$, $\min_{k_0 \leq l \leq m + 1} \| \hat{S}_l - S_* \|_{L_2(\Pi)}^2$, can be bounded with the same probability by the minimum over $l = k_0, \ldots, m + 1$ of the expression in the right-hand side of (4.10). Moreover, using monotonicity of the function $\lambda \mapsto \varphi(S; \lambda)$ and the condition that $\lambda_{l+1} \leq c \lambda_l, l = k_0, \ldots, m - 1$, it is easy to replace the minimum over $l$ by the infimum over $\varepsilon$. Combining the resulting bound with (4.9) and adjusting the constants yields the claim. □

Using more sophisticated aggregation methods (e.g., such as the methods studied in [6]) it is possible to construct an estimator $\hat{S}$ for which the oracle inequality similar to (4.7) holds with constant 1 in front of the approximation error term $\| S - S_* \|_{L_2(\Pi)}^2$.

To understand better the meaning of function $\varphi$ involved in the statements of Theorems 6 and 7, it makes sense to relate it to the low coherence assumptions discussed in the Introduction. Indeed, suppose that, for some
\( \nu = \nu(S) \geq 1, \)
\[
(4.11) \quad \| P_L \phi_k \|^2 \leq \frac{\nu r}{m}, \quad k = 1, \ldots, m.
\]

This is a part of standard low coherence assumptions on matrix \( S \) with respect to the orthonormal basis \( \{ \phi_k \} \); see \((1.2)\). Clearly, it implies that\(^6\)
\[
(4.12) \quad \bar{\varphi}(S; \lambda) \leq \frac{\nu r \bar{F}(\lambda)}{m}, \quad \lambda \geq 0.
\]

Suppose that \( n \geq m \log(2m) \) and \( \varepsilon = D a \sqrt{\frac{\log(2m)}{nm}} \). If condition \((4.12)\) holds for the target kernel \( S_* \) with \( r = \text{rank}(S_*) \) and some \( \nu \geq 1 \), then Theorem 6 implies that with probability at least \( 1 - e^{-t} \),
\[
\| \hat{S}_{\varepsilon, \bar{\varepsilon}} - S_* \|^2_{L_2(\Pi^2)} \leq C a^2 \nu r \bar{F}(\bar{\varepsilon}^{-1}) \log(2m) + \bar{\varepsilon} \| W^{1/2} S_* \|^2_{L_2(\Pi^2)} + C a^2 t_{n,m} n,
\]
and Theorem 7 implies that with the same probability,
\[
\| \hat{S} - S_* \|^2_{L_2(\Pi^2)} \leq C \inf_{\bar{\varepsilon} \in [0, \lambda_0^{-1}]} \left( \frac{a^2 \nu r \bar{F}(\bar{\varepsilon}^{-1}) \log(2m)}{n} + \bar{\varepsilon} \| W^{1/2} S_* \|^2_{L_2(\Pi^2)} \right) + C a^2 (\log(m + 1) + t_{n,m}) n.
\]

**Example.** If \( \lambda_k \asymp k^{2\beta} \) for some \( \beta > 1/2 \), then it is easy to check that \( \bar{F}(\lambda) \asymp \lambda^{1/2\beta} \). Under the assumption that \( \| W^{1/2} S_* \|^2_{L_2(\Pi^2)} \leq \rho^2 \), we get the bound
\[
\| \hat{S} - S_* \|^2_{L_2(\Pi^2)} \leq C \left( \left( \frac{a^2 \rho^{1/\beta} \nu r \log(2m)}{n} \right)^{2\beta/(2\beta + 1)} \wedge \frac{a^2 r m}{n} \right) \left( \left( \frac{a^2 (\log(m + 1) + t_{n,m})}{n} \right) \vee \frac{a^2 (\log(m + 1) + t_{n,m})}{n} \right).
\]

Under the following slightly modified version of low coherence assumption \((4.12)\),
\[
(4.14) \quad \bar{\varphi}(S; \lambda) \leq \frac{\nu (r \wedge \bar{F}(\lambda)) \bar{F}(\lambda)}{m}, \quad \lambda \geq 0,
\]
\(^6\)Compare \((4.12)\) with \((4.3)\).
one can almost recover upper bounds of Section 3,
\[ \|\hat{S} - S_*\|^2_{L_2(\Pi^2)} \leq C \left( \left( \frac{\nu a^2 r^{\beta} \log(2m)}{n} \right)^{\beta/(\beta + 1)} \wedge \left( \frac{\nu a^2 r^{\beta} \log(2m)}{n} \right)^{\beta/(\beta + 1)} \right. \]
\[ \left. \wedge \frac{a^2 rm}{n} \vee \frac{a^2 (\log(2m + 1) + t_{n,n})}{n} \right). \]

The main difference with what was proved in Section 3 is that now the low coherence constant \( \nu \) is involved in the bounds, so the methods discussed in this section yield correct (up to log factors) error rates provided that the target kernel \( S_* \) has “low coherence” with respect to the basis of eigenfunctions of \( W \).

**Proof of Theorem 6.** Bound (4.5) will be proved for a fixed oracle \( S \in \mathbb{D} \) and an arbitrary function \( \varphi \in \Psi_{S,W} \) with \( \varphi(\lambda) = \tau, \lambda \geq \lambda_m \) instead of \( \bar{\varphi} \). It then can be applied to the function \( \bar{\varphi} \) (which is the smallest function in \( \Psi_{S,W} \)). Without loss of generality, we assume that \( a = 1 \); the general case then follows by a simple rescaling. Finally, we will denote \( \hat{S} := \hat{S}_{\epsilon,\bar{\epsilon}} \) throughout the proof.

Define the following orthogonal projectors \( P_L, P_{L^\perp} \) in the space \( S_V \) with Hilbert–Schmidt inner product: \( P_L(A) := A - P_{L^\perp} A P_{L^\perp} \), \( P_{L^\perp}(A) = P_{L^\perp} A P_{L^\perp}, \) \( A \in S_V \). We will use a well known representation of subdifferential of convex function \( S \mapsto \|S\|_1 \):
\[ \partial \|S\|_1 = \{ \text{sign}(S) + P_{L^\perp}(M) : M \in S_V, \|M\| \leq 1 \}, \]
where \( L = \text{supp}(S) \); see [9], Appendix A.4 and references therein. Denote
\[ L_n(S) := \frac{1}{n} \sum_{j=1}^{n} (Y_j - S(X_j, X'_j))^2 + \epsilon \|S\|_1 + \epsilon \|W^{1/2}S\|^2_{L_2(\Pi^2)}, \]
so that \( \hat{S} := \text{argmin}_{S \in \mathbb{D}} L_n(S) \). An arbitrary matrix \( A \in \partial L_n(\hat{S}) \) can be represented as
\[ (4.15) \quad A = \frac{2}{n} \sum_{i=1}^{n} \hat{S}(X_i, X'_i) E_{X_i, X'_i} - \frac{2}{n} \sum_{i=1}^{n} Y_i E_{X_i, X'_i} + \epsilon \hat{V} + \frac{2}{m^2} W \hat{S}, \]
where \( \hat{V} \in \partial \|\hat{S}\|_1 \). Since \( \hat{S} \) is a minimizer of \( L_n(S) \), there exists a matrix \( A \in \partial L_n(\hat{S}) \) such that \( -A \) belongs to the normal cone of \( \mathbb{D} \) at the point \( \hat{S} \); see [1], Chapter 2, Corollary 6. This implies that \( \langle A, \hat{S} - S \rangle \leq 0 \) and, in view
of (4.15),
\[
2P_n(\hat{S}(\hat{S} - S)) - \left\langle \frac{2}{n} \sum_{i=1}^{n} Y_i G_{X_i, X'_i}, \hat{S} - S \right\rangle + \varepsilon(\hat{V}, \hat{S} - S) \\
+ 2 \frac{\varepsilon}{m^2} \langle W \hat{S} - \hat{S}, \hat{S} - S \rangle \leq 0.
\]
Here and in what follows, $P_n$ denotes the empirical distribution based on the sample $(X_1, X'_1, Y_1), \ldots, (X_n, X'_n, Y_n)$. The corresponding true distribution of $(X, X', Y)$ will be denoted by $P$. It easily follows from (4.16) that
\[
2\langle \hat{S} - S_s, \hat{S} - S \rangle_{L_2(P_n)} - 2\langle \Xi, \hat{S} - S \rangle
+ \varepsilon(\hat{V}, \hat{S} - S) + 2\varepsilon\langle W^{1/2} \hat{S}, W^{1/2} (\hat{S} - S) \rangle_{L_2(\Pi^2)} \leq 0,
\]
where $\Xi := \frac{1}{n} \sum_{j=1}^{n} \xi_j G_{X_j, X'_j}, \xi_j := Y_j - S_s(X_j, X'_j)$. We can now rewrite the last bound as
\[
2\langle \hat{S} - S_s, \hat{S} - S \rangle_{L_2(P)} + \varepsilon(\hat{V}, \hat{S} - S) + 2\varepsilon\langle W^{1/2} \hat{S}, W^{1/2} (\hat{S} - S) \rangle_{L_2(\Pi^2)}
\leq -2\varepsilon\langle W^{1/2} S, W^{1/2} (\hat{S} - S) \rangle_{L_2(\Pi^2)} + 2\langle \Xi, \hat{S} - S \rangle
+ 2(P - P_n)(\hat{S} - S_s)(\hat{S} - S)
\]
and use a simple identity
\[
2\langle \hat{S} - S_s, \hat{S} - S \rangle_{L_2(P)} = 2\langle \hat{S} - S_s, \hat{S} - S \rangle_{L_2(\Pi^2)}
= \|\hat{S} - S_s\|_{L_2(\Pi^2)}^2 + \|\hat{S} - S_s\|_{L_2(\Pi^2)}^2 - \|S - S_s\|_{L_2(\Pi^2)}^2
\]
to get the following bound:
\[
\|\hat{S} - S_s\|_{L_2(\Pi^2)}^2 + \|\hat{S} - S_s\|_{L_2(\Pi^2)}^2
+ 2\varepsilon\|W^{1/2} (S - S)\|_{L_2(\Pi^2)}^2 + \varepsilon(\hat{V}, \hat{S} - S)
\leq \|S - S_s\|_{L_2(\Pi^2)}^2 - 2\varepsilon\langle W^{1/2} S, W^{1/2} (S - S) \rangle_{L_2(\Pi^2)}
+ 2\langle \Xi, \hat{S} - S \rangle + 2(P - P_n)(S - S_s)(\hat{S} - S)
+ 2(P - P_n)(\hat{S} - S)^2.
\]
For an arbitrary $V \in \theta\|S\|_1$, $V = \text{sign}(S) + \mathcal{P}_L^\perp(M)$, where $M$ is a matrix with $\|M\| \leq 1$. It follows from the trace duality property that there exists an $M$ with $\|M\| \leq 1$ [to be specific, $M = \text{sign}(\mathcal{P}_L^\perp(\hat{S}))$] such that
\[
\langle \mathcal{P}_L^\perp(M), \hat{S} - S \rangle = \langle M, \mathcal{P}_L^\perp(\hat{S} - S) \rangle = \langle M, \mathcal{P}_L^\perp(S) \rangle = \|\mathcal{P}_L^\perp(\hat{S})\|_1,
\]
where the first equality is based on the fact that $\mathcal{P}_L^\perp$ is a self-adjoint operator and the second equality is based on the fact that $S$ has support $L$. Using this equation and monotonicity of subdifferentials of convex functions, we
get \( \langle \text{sign}(S), \hat{S} - S \rangle + \|P_L^\perp(\hat{S}) \|_1 = \langle V, \hat{S} - S \rangle \leq \langle \hat{V}, \hat{S} - S \rangle \). Substituting this into the left-hand side of (4.17), it is easy to get

\[
\|\hat{S} - S\|_2^2 + \|\hat{S} - S\|_2^2 \\
+ \varepsilon \|P_L^\perp(\hat{S}) \|_1 + 2\varepsilon \|W^{1/2}(\hat{S} - S)\|_2^2 \\
\leq \|S - S\|_2^2 - \varepsilon \langle \text{sign}(S), \hat{S} - S \rangle \\
- 2\varepsilon \langle W^{1/2} S, W^{1/2}(\hat{S} - S) \rangle_2^2 \\
+ 2\langle \Xi, \hat{S} - S \rangle + 2(P - P_n)(S - S)(\hat{S} - S) \\
+ 2(P - P_n)(\hat{S} - S)^2.
\]

(4.18)

We need to bound the right-hand side of (4.18). We start with deriving a bound on \( \langle \text{sign}(S), \hat{S} - S \rangle \), expressed in terms of function \( \varphi \). Note that, for all \( \lambda > 0 \),

\[
\langle \text{sign}(S), \hat{S} - S \rangle = \sum_{k=1}^m \langle \text{sign}(S)\phi_k, (\hat{S} - S)\phi_k \rangle \\
= \sum_{\lambda_k \leq \lambda} \langle \text{sign}(S)\phi_k, (\hat{S} - S)\phi_k \rangle \\
+ \sum_{\lambda_k > \lambda} \langle \frac{\text{sign}(S)\phi_k}{\sqrt{\lambda_k}}, \sqrt{\lambda_k}(\hat{S} - S)\phi_k \rangle.
\]

which easily implies

\[
|\langle \text{sign}(S), \hat{S} - S \rangle| \\
\leq \left( \sum_{\lambda_k \leq \lambda} \|\text{sign}(S)\phi_k\|^2 \right)^{1/2} \left( \sum_{\lambda_k \leq \lambda} \|(\hat{S} - S)\phi_k\|^2 \right)^{1/2} \\
+ \left( \sum_{\lambda_k > \lambda} \frac{\|\text{sign}(S)\phi_k\|^2}{\lambda_k} \right)^{1/2} \left( \sum_{\lambda_k > \lambda} \lambda_k\|(\hat{S} - S)\phi_k\|^2 \right)^{1/2} \\
\leq \left( \sum_{\lambda_k \leq \lambda} \|P_L\phi_k\|^2 \right)^{1/2} \|\hat{S} - S\|_2 + \left( \sum_{\lambda_k > \lambda} \frac{\|P_L\phi_k\|^2}{\lambda_k} \right)^{1/2} \|W^{1/2}(\hat{S} - S)\|_2.
\]

(4.19)

We will now use the following elementary lemma.

**Lemma 1.** Let \( c_\gamma := \frac{\varepsilon + \gamma}{\gamma} \). For all \( \lambda > 0 \),

\[
\sum_{\lambda_k > \lambda} \frac{\|P_L\phi_k\|^2}{\lambda_k} \leq c_\gamma \varphi(\lambda) \frac{\phi(\lambda)}{\lambda} \quad \text{and} \quad \sum_{\lambda_k > \lambda} \frac{1}{\lambda_k} \leq c_\gamma \tilde{F}(\lambda) \frac{\phi(\lambda)}{\lambda}.
\]
Proof. Denote \( H_k := \sum_{j=1}^l \| P_L \phi_j \|^2, k = 1, \ldots, m \). Suppose that \( \lambda \in [\lambda_l, \lambda_{l+1}] \) for some \( l = k_0 - 1, \ldots, m - 1 \). We will use the properties of functions \( \varphi \in \Psi_{S,W} \) and \( \bar{F} \). In particular, recall that the functions \( \frac{\varphi(\lambda)}{F(\lambda)} \) and \( \frac{\bar{F}(\lambda)}{\lambda} \) are nonincreasing. Using these properties and the condition that \( \lambda_{k+1} \leq c \lambda_k, k \geq k_0 \) we get

\[
\sum_{\lambda_k > \lambda} \frac{\| P_L \phi_k \|^2}{\lambda_k} = \sum_{k=l+1}^{m-1} H_k \left( \frac{1}{\lambda_k} - \frac{1}{\lambda_{k+1}} \right) + \frac{H_m}{\lambda_m} - \frac{H_l}{\lambda_{l+1}}
\]

\[
\leq \sum_{k=l+1}^{m-1} \varphi(\lambda_k) \left( \frac{1}{\lambda_k} - \frac{1}{\lambda_{k+1}} \right) + \frac{\varphi(\lambda_m)}{\lambda_m}
\]

\[
\leq c \sum_{k=l+1}^{m-1} \frac{\varphi(\lambda_{k+1})}{\lambda_k} (\lambda_{k+1} - \lambda_k) + \frac{\varphi(\lambda_m)}{\lambda_m}
\]

\[
\leq c \int_{\lambda}^{\infty} \frac{\varphi(s)}{s^2} ds + \frac{\varphi(\lambda)}{\lambda} \leq c \int_{\lambda}^{\infty} \frac{\varphi(s)}{F(s)} \frac{\bar{F}(s)}{s^2} ds + \frac{\varphi(\lambda)}{\lambda}
\]

\[
\leq c \frac{\varphi(\lambda)}{F(\lambda)} \int_{\lambda}^{\infty} \frac{\bar{F}(s)}{s^2} ds + \frac{\varphi(\lambda)}{\lambda} \leq c \frac{\varphi(\lambda)}{\gamma F(\lambda)} \frac{\bar{F}(\lambda)}{\lambda} + \frac{\varphi(\lambda)}{\lambda}
\]

\[
= \frac{c + \gamma \varphi(\lambda)}{\lambda},
\]

which proves the first bound. To prove the second bound, replace in the inequalities above \( \| P_L \phi_k \|^2 \) by 1 and \( \varphi(\lambda) \) by \( \bar{F}(\lambda) \). In the case when \( \lambda \geq \lambda_m \), both bounds are trivial since their left-hand sides are equal to zero. \( \square \)

It follows from from (4.19) and the first bound of Lemma 1 that

\[
|\langle \text{sign}(S), \hat{S} - S \rangle| \leq \sqrt{\varphi(\lambda)} \| \hat{S} - S \|_2 + \sqrt{c_\gamma \frac{\varphi(\lambda)}{\lambda} \| W^{1/2}(\hat{S} - S) \|_2}
\]

\[
= m \sqrt{\varphi(\lambda)} \| \hat{S} - S \|_{L_2(\Pi^2)} + m \sqrt{c_\gamma \frac{\varphi(\lambda)}{\lambda}} \| W^{1/2}(\hat{S} - S) \|_{L_2(\Pi^2)}.
\]

This implies the following bound:

\[
\varepsilon |\langle \text{sign}(S), \hat{S} - S \rangle| \leq \varphi(\lambda) m^2 \varepsilon^2 + \frac{1}{4} \| \hat{S} - S \|_{L_2(\Pi^2)}^2 + c_\gamma \frac{\varphi(\lambda)}{\lambda} \varepsilon^2
\]

\[
+ \frac{\bar{\varepsilon}}{4} \| W^{1/2}(\hat{S} - S) \|_{L_2(\Pi^2)}^2.
\]
where we used twice an elementary inequality \(ab \leq a^2 + \frac{1}{4}b^2, a, b > 0\). We will apply this bound for \(\lambda = \tilde{\epsilon}^{-1}\) to get the following inequality:

\[
\epsilon|\langle \text{sign}(S), \hat{S} - S \rangle| \leq (c_\gamma + 1)\varphi(\tilde{\epsilon}^{-1})m^2\tilde{\epsilon}^2 + \frac{1}{4}\|\hat{S} - S\|_{L_2(\Pi^2)}^2 + \frac{\tilde{\epsilon}}{4}\|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)}^2.
\]

(4.22)

To bound the next term in the right-hand side of (4.18), note that

\[
\tilde{\epsilon}|\langle W^{1/2}S, W^{1/2}(\hat{S} - S) \rangle|_{L_2(\Pi^2)} \leq \tilde{\epsilon}\|W^{1/2}S\|_{L_2(\Pi^2)}^2 + \frac{\tilde{\epsilon}}{4}\|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)}^2.
\]

(4.23)

The main part of the proof deals with bounding the stochastic term

\[
2\langle \Xi, \hat{S} - S \rangle + 2(P - P_n)(S - S_*)(\hat{S} - S) + 2(P - P_n)(\hat{S} - S)^2
\]

on the right-hand side of (4.18). To this end, define (for fixed \(S, S_*)\)

\[
f_A(y, u, v) := (y - S_*(u, v))(A - S)(u, v) - (S - S_*)(u, v)(A - S)(u, v) - (A - S)^2(u, v)
\]

\[
= (y - S(u, v))(A - S)(u, v) - (A - S)^2(u, v),
\]

and consider the following empirical process:

\[
a_n(\delta_1, \delta_2, \delta_3) := \sup\{||(P_n - P)(f_A)|| : A \in T(\delta_1, \delta_2, \delta_3)\},
\]

where

\[T(\delta_1, \delta_2, \delta_3) := \{A \in \mathcal{D} : \|A - S\|_{L_2(\Pi^2)} \leq \delta_1, \|P_A^L\|_1 \leq \delta_2, \|W^{1/2}(A - S)\|_{L_2(\Pi^2)} \leq \delta_3\}.
\]

Clearly, we have

\[
2\langle \Xi, \hat{S} - S \rangle + 2(P - P_n)(S - S_*)(\hat{S} - S) + 2(P - P_n)(\hat{S} - S)^2
\]

(4.24)

\[
\leq 2a_n(\|\hat{S} - S\|_{L_2(\Pi^2)}, \|P_A^L\|_1, \|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)}),
\]

and it remains to provide an upper bound on \(a_n(\delta_1, \delta_2, \delta_3)\) that is uniform in some intervals of the parameters \(\delta_1, \delta_2, \delta_3\) (such that either the norms \(\|\hat{S} - S\|_{L_2(\Pi^2)}, \|P_A^L\|_1, \|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)}\) belong to these intervals with a high probability, or bound of the theorem trivially holds). Note that the functions \(f_A\) are uniformly bounded by a numerical constant (under the assumptions that \(a = 1, |Y| \leq a\) and all the kernels are also bounded by \(a\)) and we have \(Pf_A \leq c_1\|A - S\|_{L_2(\Pi)}^2\) with some numerical constant \(c_1 > 0\). Using Talagrand’s concentration inequality for empirical processes we conclude
that for fixed $\delta_1, \delta_2, \delta_3$ with probability at least $1 - e^{-t}$ and with some constant $c_2 > 0$ $\alpha_n(\delta_1, \delta_2, \delta_3) \leq 2\mathbb{E}\alpha_n(\delta_1, \delta_2, \delta_3) + c_2(\delta_1 \sqrt{\frac{L}{n}} + \frac{\bar{t}}{n})$. We will make this bound uniform in $\delta_k \in [\delta_k^-, \delta_k^+]$, $\delta_k^-, \delta_k^+ < \delta_k^+$, $k = 1, 2, 3$ (these intervals will be chosen later). Define $\delta_k^j := \delta_k^+ 2^{-j}$, $j = 0, \ldots, \lfloor \log_2(\delta_k^+ / \delta_k^-) \rfloor$ and let $t := t + \sum_{k=1}^3 \log(\lfloor \log_2(\delta_k^+ / \delta_k^-) \rfloor + 2)$. By the union bound, with probability at least $1 - e^{-t}$ and for all $j_k = 0, \ldots, \lfloor \log_2(\delta_k^+ / \delta_k^-) \rfloor + 1, k = 1, 2, 3,$ $\alpha_n(\delta_1^j, \delta_2^j, \delta_3^j) \leq 2\mathbb{E}\alpha_n(\delta_1^j, \delta_2^j, \delta_3^j) + c_2(\delta_1^j \sqrt{\frac{L}{n}} + \frac{\bar{t}}{n})$. By monotonicity of $\alpha_n$ and of the right-hand side of the bound with respect to each of the variables $\delta_1, \delta_2, \delta_3$, we conclude that with the same probability and with some numerical constant $c_3 > 0$, for all $\delta_k \in [\delta_k^-, \delta_k^+]$, $k = 1, 2, 3,$

\begin{equation}
\alpha_n(\delta_1, \delta_2, \delta_3) \leq 2\mathbb{E}\alpha_n(\delta_1, \delta_2, \delta_3) + c_3\left(\delta_1 \sqrt{\frac{L}{n}} + \frac{\bar{t}}{n}\right).
\end{equation}

To bound the expectation $\mathbb{E}\alpha_n(2\delta_1, 2\delta_2, 2\delta_3)$ on the right-hand side of (4.25), note that, by the definition of function $f_A$,

\begin{equation}
\mathbb{E}\alpha_n(\delta_1, \delta_2, \delta_3) \leq \mathbb{E}\sup\{||P_n - P)(y - S)(A - S)| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}
+ \mathbb{E}\sup\{||(P_n - P)(A - S)^2| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}.
\end{equation}

A standard application of symmetrization inequality followed by contraction inequality for Rademacher sums (see, e.g., [9], Chapter 2) yields

\begin{equation}
\mathbb{E}\sup\{||(P_n - P)(A - S)^2| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}
\leq 16\mathbb{E}\sup\{||R_n(A - S)| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}.
\end{equation}

It easily follows from (4.26) and (4.27) that

\begin{equation}
\mathbb{E}\alpha_n(\delta_1, \delta_2, \delta_3) \leq \mathbb{E}\sup\{||\Xi_1, A - S)| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}
+ 16\mathbb{E}\sup\{||\Xi_2, A - S)| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\},
\end{equation}

where $\Xi_1 := \frac{1}{n} \sum_{j=1}^n (Y_j - S(X_j, X_j')) E X_j, X_j'$ and $\Xi_2 := \frac{1}{n} \sum_{j=1}^n \varepsilon_j E X_j, X_j'$ being i.i.d. Rademacher random variables independent of $(X_1, X_1', Y_1), \ldots, (X_n, X_n', Y_n)$. We will upper bound the expectations on the right-hand side of (4.28), which reduces to bounding $\mathbb{E}\sup\{||\Xi_1, A - S)| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}$ for each of the random matrices $\Xi_1, \Xi_2$. For $i = 1, 2$ and $A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)$, we have

\begin{equation}
||\Xi_i, A - S)| \leq ||\Xi_i, P_L(A - S)| + ||\Xi_i, P_L^\perp(A)||
\leq ||P_L\Xi_i, A - S)| + ||\Xi_i, ||P_L^\perp(A)||_1
\leq ||P_L\Xi_i, A - S)| + \delta_2||\Xi_i||. \end{equation}

To bound $||\Xi_i||$, we use the following simple corollary of a well-known non-commutative Bernstein inequality (see, e.g., [16]) obtained by integrating
exponential tails of this inequality: let $Z$ be a random symmetric matrix with $\mathbb{E}Z = 0$, $\sigma^2_Z := \|\mathbb{E}Z^2\|$ and $\|Z\| \leq U$ for some $U > 0$ and let $Z_1, \ldots, Z_n$ be $n$ i.i.d. copies of $Z$. Then
\begin{equation}
\mathbb{E}\left\|\frac{1}{n} \sum_{j=1}^{n} Z_j\right\| \leq 4 \left(\sigma_Z \sqrt{\frac{\log(2m)}{n}} \vee \frac{U \log(2m)}{n}\right).
\end{equation}

It is applied to i.i.d. random matrices
\[
Z_j := (Y_j - S(X_j, X'_j))E_{X_j, X'_j} - \mathbb{E}(Y - S(X, X'))E_{X, X'},
\]
in the case of matrix $\Xi_1$ and to i.i.d. random matrices $Z_j := \epsilon_j E_{X_j, X'_j}$ in the case of matrix $\Xi_2$. In both cases, $\|Z_j\| \leq 4$ and, by a simple computation, $\sigma^2_{Z, j} := \|\mathbb{E}Z^2\| \leq 4/m$ (see, e.g., [9], Section 9.4), bound (4.30) implies that, for $i = 1, 2$,
\begin{equation}
\mathbb{E}\|\Xi_i\| \leq 16 \left(\frac{\sqrt{\log(2m)}}{nm} \vee \frac{\log(2m)}{n}\right) =: \epsilon^*.
\end{equation}

To control the term $|\langle P_L \Xi_i, A - S \rangle|$ in bound (4.29), we will use the following lemma.

**Lemma 2.** For all $\delta > 0$,
\[
\mathbb{E}\sup_{\|M\| \leq \delta, \|W^{1/2} M\| \leq 1} |\langle P_L \Xi_i, M \rangle| \leq 4 \sqrt{2} \sqrt{c_\gamma + 1} \left(\frac{1}{nm} \right)^{1/2} \sqrt{\phi(\delta^{-2})}.
\]

**Proof.** For all symmetric $m \times m$ matrices $M$,
\[
\langle P_L \Xi_i, M \rangle = \sum_{k,j=1}^{m} \langle P_L \Xi_i, \phi_k \otimes \phi_j \rangle \langle M, \phi_k \otimes \phi_j \rangle.
\]

Assuming that
\[
\|M\|^2 = \sum_{k,j=1}^{m} |\langle M, \phi_k \otimes \phi_j \rangle|^2 \leq \delta^2 \quad \text{and}
\]
\[
\|W^{1/2} M\|^2 = \sum_{k,j=1}^{m} \lambda_k |\langle M, \phi_k \otimes \phi_j \rangle|^2 \leq 1,
\]
it is easy to conclude that $\sum_{k,j=1}^{m} \frac{|\langle M, \phi_k \otimes \phi_j \rangle|^2}{\lambda_k^{-1} \wedge \delta^2} \leq 2$. It follows
\begin{equation}
|\langle P_L \Xi_i, M \rangle| \leq \left(\sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) |\langle P_L \Xi_i, \phi_k \otimes \phi_j \rangle|^2\right)^{1/2} \left(\sum_{k,j=1}^{m} \frac{|\langle M, \phi_k \otimes \phi_j \rangle|^2}{\lambda_k^{-1} \wedge \delta^2}\right)^{1/2}
\end{equation}
Consider the following inner product:

$$\langle M_1, M_2 \rangle_w := \sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \langle M_1, \phi_k \otimes \phi_j \rangle \langle M_2, \phi_k \otimes \phi_j \rangle,$$

and let $\| \cdot \|_w$ be the corresponding norm. We will provide an upper bound on $\mathbb{E} \| P_L \Xi_i \|_w = \mathbb{E}(\sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \langle P_L \Xi_i, \phi_k \otimes \phi_j \rangle^2)^{1/2}$. Recall that $\Xi_i = n^{-1} \sum_{j=1}^{n} \zeta_j E_{X_j, X'_j} - \mathbb{E}(\zeta E_{X, X'})$, where $\zeta_j = Y_j - S(X_j, X'_j)$ for $i = 1$ and $\zeta_j = \varepsilon_j$ for $i = 2$. Note that in the first case $|\zeta_j| \leq 2$, and in the second case $|\zeta_j| \leq 1$. Therefore,

$$\mathbb{E} \| P_L \Xi_i \|_w \leq \mathbb{E}^{1/2} \| P_L \Xi_i \|_w^2 \leq \sqrt{\frac{\mathbb{E} \zeta^2 \| P_L E_{X, X'} \|_{w}^2}{n}},$$

(4.33)

$$\leq 2 \sqrt{\frac{\mathbb{E} \| P_L E_{X, X'} \|_{w}^2}{n}}.$$

It remains to bound $\mathbb{E} \| P_L E_{X, X'} \|_{w}^2$.

$$\mathbb{E} \| P_L (E_{X, X'}) \|_{w}^2$$

$$= \mathbb{E} \sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L (E_{X, X'}), \phi_k \otimes \phi_j \|^2$$

$$= \sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) m^{-2} \sum_{u,v \in V} |\langle E_{u,v}, P_L (\phi_k \otimes \phi_j) \rangle|^2$$

(4.34)

$$\leq m^{-2} \sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L (\phi_k \otimes \phi_j) \|_2^2$$

$$\leq 2 m^{-2} \sum_{k,j=1}^{m} (\lambda_k^{-1} \wedge \delta^2) (\| P_L \phi_k \|^2 + \| P_L \phi_j \|^2)$$

$$= 2 m^{-1} \sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L \phi_k \|^2 + 2 m^{-2} \sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L \|^2$$

$$= 2 m^{-1} \sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L \phi_k \|^2 + 2 m^{-2} \sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2).$$

Note that

$$\sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \| P_L \phi_k \|^2 \leq \delta^2 \sum_{\lambda_k \leq \delta^{-2}} \| P_L \phi_k \|^2 + \sum_{\lambda_k > \delta^{-2}} \lambda_k^{-1} \| P_L \phi_k \|^2.$$

(4.35)
Using the first bound of Lemma 1, we get from (4.35) that
\[
\sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \|P_L \phi_k\|^2 \leq \delta^2 \varphi(\delta^{-2}) + c_\gamma \delta^2 \varphi(\delta^{-2})
\]
(4.36)
\[
= (c_\gamma + 1)\delta^2 \varphi(\delta^{-2}).
\]
We also have \( \sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \leq \sum_{\lambda_k \leq \delta^{-2}} \delta^2 + \sum_{\lambda_k > \delta^{-2}} \lambda_k^{-1} \), which, by the second bound of Lemma 1, implies that
\[
\sum_{k=1}^{m} (\lambda_k^{-1} \wedge \delta^2) \leq \delta^2 \bar{F}(\delta^{-2}) + c_\gamma \delta^2 \bar{F}(\delta^{-2}) \leq (c_\gamma + 1)\delta^2 \bar{F}(\delta^{-2}).
\]
(4.37)
Using bounds (4.34), (4.36) and (4.37) and the fact that \( \varphi(\lambda) \geq \frac{\lambda}{m} \bar{F}(\lambda) \), we get
\[
\mathbb{E}\|P_L (E_{X,X})\|^2 \leq 2m^{-1}(c_\gamma + 1)\delta^2 \varphi(\delta^{-2}) + 2m^{-2}r(c_\gamma + 1)\delta^2 \bar{F}(\delta^{-2})
\]
(4.38)
\[
\leq 4m^{-1}(c_\gamma + 1)\delta^2 \varphi(\delta^{-2}).
\]
The proof follows from (4.32), (4.33) and (4.38). \( \square \)

Let \( \delta := \frac{\delta_1}{\delta_2} \). Using Lemma 2, we get
\[
\mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : A \in T(\delta_1, \delta_2, \delta_3)\}
\leq \mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : \|A - S\|_{L_2(\Pi^2)} \leq \delta_1, \|W^{1/2}(A - S)\|_{L_2(\Pi^2)} \leq \delta_3\}
\leq \mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : \|A - S\|_2 \leq \delta_1 m, \|W^{1/2}(A - S)\|_2 \leq \delta_3 m\}
\leq \delta_3 m \mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : \|A - S\|_2 \leq \delta_1, \|W^{1/2}(A - S)\|_{L_2(\Pi^2)} \leq 1\}
\leq 4\sqrt{2}\delta_3 m \sqrt{c_\gamma + 1} \sqrt{\frac{1}{mn} \delta \sqrt{\varphi(\delta^{-2})}} = 4\sqrt{2} \sqrt{c_\gamma + 1} \sqrt{\frac{m}{n} \delta_1 \sqrt{\varphi(\delta^{-2})}}.
\]
In the case when \( \delta^2 \geq \bar{\varepsilon} \), we get
\[
\mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : A \in T(\delta_1, \delta_2, \delta_3)\} \leq 4\sqrt{2} \sqrt{c_\gamma + 1} \delta_1 \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}}.
\]
In the opposite case, when \( \delta^2 < \bar{\varepsilon} \), we use the fact that the function \( \frac{\varphi(\lambda)}{\bar{F}(\lambda)} \) is nonincreasing. This implies that \( \delta^2 \varphi(\delta^{-2}) \leq \bar{\varepsilon} \varphi(\bar{\varepsilon}^{-1}) \), and we get
\[
\mathbb{E}\sup\{|\langle P_L \Xi_i, A - S \rangle : A \in T(\delta_1, \delta_2, \delta_3)\}
\leq 4\sqrt{2} \sqrt{c_\gamma + 1} \sqrt{\frac{m}{n} \delta_1 \sqrt{\varphi(\bar{\varepsilon}^{-2})}} = 4\sqrt{2} \sqrt{c_\gamma + 1} \sqrt{\frac{m}{n} \delta_3 \sqrt{\delta^2 \varphi(\delta^{-2})}}
\leq 4\sqrt{2} \sqrt{c_\gamma + 1} \sqrt{\frac{m}{n} \delta_3 \sqrt{\bar{\varepsilon} \varphi(\bar{\varepsilon}^{-1})}} = 4\sqrt{2} \sqrt{c_\gamma + 1} \sqrt{\bar{\varepsilon} \delta_3} \sqrt{\frac{m \varphi(\bar{\varepsilon}^{-1})}{n}}.
\]
We can conclude that
\[
\mathbb{E}\sup\{|\langle \mathcal{P}_L \Xi_i, A - S \rangle| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}
\leq 4\sqrt{2} \sqrt{c_\gamma + 1}\delta_1 \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} + 4\sqrt{2} \sqrt{c_\gamma + 1}\sqrt{\bar{\varepsilon}\delta_3} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}}.
\]
This bound will be combined with (4.29) and (4.31) to get that, for \(i = 1, 2,\)
\[
\mathbb{E}\sup\{|\langle \Xi_i, A - S \rangle| : A \in \mathcal{T}(\delta_1, \delta_2, \delta_3)\}
\leq \varepsilon^* \delta_2 + 4\sqrt{2} \sqrt{c_\gamma + 1}\delta_1 \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} + 4\sqrt{2} \sqrt{c_\gamma + 1}\sqrt{\delta_3} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}}.
\]
In view of (4.28), this yields the bound
\[
\mathbb{E}\alpha_n(\delta_1, \delta_2, \delta_3) \leq C' \varepsilon^* \delta_2 + C' \delta_1 \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} + C' \sqrt{\delta_3} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}}
\]
that holds with some constant \(C' > 0\) for all \(\delta_1, \delta_2, \delta_3 > 0.\) Using (4.25), we conclude that for some constants \(C\) and for all \(\delta_k \in [\delta_k^-, \delta_k^+], k = 1, 2, 3,\)
\[
\alpha_n(\delta_1, \delta_2, \delta_3) \leq C \left[ \delta_1 \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} + \delta_1 \sqrt{\frac{\bar{t}}{n}} + \frac{\bar{t}}{n} + \varepsilon^* \delta_2 + \sqrt{\delta_3} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} \right]
\]
that holds with probability at least \(1 - e^{-t}.\) This yields the following upper bound on the stochastic term in (4.18) [see also (4.24)]:
\[
2\langle \Xi, \hat{S} - S \rangle + 2(P - P_n)(S - S_n)(\hat{S} - S) + 2(P - P_n)(\hat{S} - S)^2
\]
\[
\leq 2C \left[ \|\hat{S} - S\|_{L_2(\Pi^2)} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} + \|\hat{S} - S\|_{L_2(\Pi^2)} \sqrt{\frac{\bar{t}}{n}} + \frac{\bar{t}}{n} 
\right.
\]
\[
\left. + \varepsilon^* \|\mathcal{P}_L \hat{S}\|_1 + \sqrt{\bar{\varepsilon}} \|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} \right]
\]
that holds provided that
\[
\|\hat{S} - S\|_{L_2(\Pi^2)} \in [\delta_1^-, \delta_1^+], \quad \|\mathcal{P}_L \hat{S}\|_1 \in [\delta_2^-, \delta_2^+],
\]
\[
\|W^{1/2}(\hat{S} - S)\|_{L_2(\Pi^2)} \in [\delta_3^-, \delta_3^+].
\]
We substitute bound (4.39) in (4.18) and further bound some of its terms as follows:
\[
2C \|\hat{S} - S\|_{L_2(\Pi^2)} \sqrt{\frac{m\varphi(\bar{\varepsilon}^{-1})}{n}} \leq \frac{1}{8} \|\hat{S} - S\|_{L_2(\Pi^2)}^2 + 8C^2 \frac{m\varphi(\bar{\varepsilon}^{-1})}{n},
\]
\[
2C \|\hat{S} - S\|_{L_2(\Pi^2)} \sqrt{\frac{\bar{t}}{n}} \leq \frac{1}{8} \|\hat{S} - S\|_{L_2(\Pi^2)}^2 + 8C^2 \frac{\bar{t}}{n}.
\]
Then it is straightforward to check that inequality (4.18) holds with $D \geq 32C$, then $\varepsilon \geq 2C\varepsilon^*$. By a simple algebra, it follows from (4.18) that

$$
\|\hat{S} - S_*\|_{L^2(\Pi^2)}^2 \leq \|S - S_*\|_{L^2(\Pi^2)}^2 + C_1 m^2 \varepsilon^2 \varphi(\varepsilon^{-1}) + C_1 \frac{m \varphi(\varepsilon^{-1})}{n} + \hat{\varepsilon} \|W^{1/2}S\|_{L^2(\Pi^2)}^2 + \frac{\tilde{t}}{n}
$$

with some constant $C_1 > 0$. Since, under condition (4.4) with $a = 1$, $m^2 \varepsilon^2 \geq D^2 \frac{m \log(2m)}{n} \geq D^2 \frac{m}{n}$, we can conclude that

$$
\|\hat{S} - S_*\|_{L^2(\Pi^2)}^2 \leq \|S - S_*\|_{L^2(\Pi^2)}^2 + C_2 m^2 \varepsilon^2 \varphi(\varepsilon^{-1}) + \hat{\varepsilon} \|W^{1/2}S\|_{L^2(\Pi^2)}^2 + \frac{\tilde{t}}{n}
$$

with some constant $C_2 > 0$.

We still have to choose the values of $\delta_k^-, \delta_k^+$ and to handle the case when conditions (4.40) do not hold. First note that due to the assumption that $\|S\|_{L^\infty} \leq 1, S \in \mathcal{D}$, we have $\|\hat{S} - S\|_{L^2(\Pi)} \leq 2, \|\mathcal{P}_\mathcal{L} \hat{S}\|_1 \leq \|\hat{S}\|_1 \leq \sqrt{m} \|\hat{S}\|_2 \leq m^{3/2}$ and $\|W^{1/2}(\hat{S} - S)\|_{L^2(\Pi^2)} \leq 2 \sqrt{\lambda_m}$. Thus, we can set $\delta_1^+ := 2, \delta_2^+ := m^{3/2}, \delta_3^+ := 2 \sqrt{\lambda_m}$, which guarantees that the upper bounds of (4.40) are satisfied. We will also set $\delta_1^- := \delta_2^- := m^{-1/2}, \delta_3^- := \sqrt{\frac{\Delta}{n}}$. In the case when one of the lower bounds of (4.40) does not hold, we can still use inequality (4.39), but we have to replace each of the norms $\|\hat{S} - S\|_{L^2(\Pi)}, \|\mathcal{P}_\mathcal{L} \hat{S}\|_1, \|W^{1/2}(\hat{S} - S)\|_{L^2(\Pi^2)}$ which are smaller than the corresponding $\delta_k^-$ by the quantity $\delta_k^-$. Then it is straightforward to check that inequality (4.41) still holds for some value of constant $C_2 > 0$. With the above choice of $\delta_k^-, \delta_k^+$, we have $\hat{t} \leq t + 3 \log(2 \log_2 n + \frac{1}{2} \log_2 \frac{\Delta}{\lambda} + 2) = t_{n,m}$. This completes the proof. □
