Linoleic acid (LA; 18:2 n-6), the most abundant polyunsaturated fatty acid in the US diet, is a precursor to oxidized metabolites that have unknown roles in the brain. Here, we show that oxidized LA-derived metabolites accumulate in several rat brain regions during CO2-induced ischemia and that LA-derived 13-hydroxyoctadecadienoic acid, but not LA, increase somatic paired-pulse facilitation in rat hippocampus by 80%, suggesting bioactivity. This study provides new evidence that LA participates in the response to ischemia-induced brain injury through oxidized metabolites that regulate neurotransmission. Targeting this pathway may be therapeutically relevant for ischemia-related conditions such as stroke.

Omega-6 linoleic acid (LA, 18:2 n-6) is the most consumed polyunsaturated fatty acid (PUFA) in the US diet, accounting for approximately 7% of daily calories1. The consumption of its elongation-desaturation product, arachidonic acid (AA, 20:4n-6), as well as omega-3 α-linolenic acid (ALA, 18:3n-3), eicosapentaenoic acid (EPA, 20:5n-3) and docosahexaenoic acid (DHA, 22:6n-3), collectively account for less than 1% of calories. Despite being the main PUFA in the diet, little is known about the role of LA in the brain.

Most brain studies have focused on AA and DHA, because they are enriched in phospholipid membranes, and are known to regulate many processes including blood flow2-4, pain signaling5-7, inflammation8 and the resolution of inflammation9-13 through oxidized metabolites known as oxylipins. PUFA-derived oxylipins are synthesized via lipoxygenase (LOX)14-16, cyclooxygenase (COX)15,17,18, cytochrome P450 (CYP450)19-21 or soluble epoxide hydrolase (sEH) enzymes6,22 following phospholipase-mediated release of fatty acids from brain membrane phospholipids23,24. Oxylipin synthesis can also occur non-enzymatically25-27.

Unlike AA and DHA, which make up over 20% of brain total fatty acids, LA accounts for less than 2% of total fatty acids28, but enters the brain at a comparable rate to AA and DHA (4–7 pmol/g/s)29,30. Instead of incorporating into membrane phospholipids, however, up to 59% of the LA entering the brain is converted into relatively polar compounds31, which include LA-derived oxylipins32 produced non-enzymatically or via the same LOX, COX, CYP450 and sEH enzymes that act on AA and DHA17,32-34.

Brain injury caused by hypoxia, ischemia, seizures or trauma activates excitatory N-methyl-D-aspartate (NMDA) receptors coupled to phospholipase enzymes35-37, which release AA and DHA from membrane phospholipids38-40. The majority of unesterified AA and DHA are re-esterified into the phospholipid membrane41, whereas a small portion (~3%) is converted via non-enzymatic or enzymatic pathways into oxylipins41,42-47 that...
DHA28, its metabolites were abundant. 

Ischemia increased LA-derived metabolites in various brain regions. LA-derived oxylipins were significantly increased in various brain regions following ischemia compared to MW-fixed controls (Fig. 2). 13-HODE was 1.7-fold higher in the ischemic CO₂-group compared to MW-fixed controls in cortex (p = 0.0098). 9-HODE was also increased in cortex by 1.8-fold in the ischemic CO₂-group compared to MW-fixed controls (p = 0.0439). 13-oxo-ODE was increased 5.6-fold in cortex (p = 0.0499) and by 3.2-fold in brainstem (p = 0.0134). 12(13)-EpOME was increased in both hippocampus (5.7-fold; p = 0.023) and cerebellum (2.7; p < 0.001), whereas 9(10)-EpOME was increased 2.8-fold in cerebellum (p < 0.001) of

### Table 1. Number of oxylipins detected in cortex, hippocampus, cerebellum and brainstem in the control (n = 7–9) and ischemic groups (n = 7–9 per group) relative to the total number of metabolites analyzed (in brackets).

|                     | Cortex | Hippocampus | Cerebellum | Brainstem |

Ischemia induced global changes in oxylipin concentrations. Targeted LC-MS/MS analysis detected the presence of 53, 34, 43 and 37 oxylipins in cortex, hippocampus, cerebellum and brainstem, respectively. As shown in Table 1, the majority of oxylipins were present in cortex, and many that were not detected in MW-fixed control brains, were present upon ischemia.

A heat map depicting the oxylipins common to all 4 brain regions in control and ischemic brains is shown in Fig. 1. As indicated, many LA, AA and DHA metabolites were abundant in all brain regions at baseline, and increased markedly following ischemia. Interestingly, although LA itself is low in brain compared to AA and DHA, its metabolites were abundant.

Results

Ischemia induced global changes in oxylipin concentrations. Targeted LC-MS/MS analysis detected the presence of 53, 34, 43 and 37 oxylipins in cortex, hippocampus, cerebellum and brainstem, respectively. As shown in Table 1, the majority of oxylipins were present in cortex, and many that were not detected in MW-fixed control brains, were present upon ischemia.

A heat map depicting the oxylipins common to all 4 brain regions in control and ischemic brains is shown in Fig. 1. As indicated, many LA, AA and DHA metabolites were abundant in all brain regions at baseline, and increased markedly following ischemia. Interestingly, although LA itself is low in brain compared to AA and DHA, its metabolites were abundant.

Ischemia increased LA-derived metabolites in various brain regions. LA-derived oxylipins were significantly increased in various brain regions following ischemia compared to MW-fixed controls (Fig. 2). 13-HODE was 1.7-fold higher in the ischemic CO₂-group compared to MW-fixed controls in cortex (p = 0.0115) and brainstem (p = 0.0098). 9-HODE was also increased in cortex by 1.8-fold in the ischemic CO₂-group compared to MW-fixed controls (p = 0.0439). 13-oxo-ODE was increased 5.6-fold in cortex (p = 0.0499) and by 3.2-fold in brainstem (p = 0.0134). 12(13)-EpOME was increased in both hippocampus (5.7-fold; p = 0.023) and cerebellum (2.7; p < 0.001), whereas 9(10)-EpOME was increased 2.8-fold in cerebellum (p < 0.001) of
ischemic rats compared to MW-fixed controls. Brainstem concentrations of 12,13-DiHOME increased by 1.4-fold ($p = 0.0088$), following CO$_2$-induced ischemia.

**Ischemia increased AA-derived metabolites in various brain regions.** Previous studies reported an increase in the formation of AA- and DHA-derived oxylipins following hypoxia or ischemic brain injury$^{41, 49}$. To confirm that these changes occurred in the present study, regional changes in AA- and DHA-derived metabolites were measured by LC-MS/MS as shown in Figs 3 and 4, respectively.

Compared to the MW-fixed controls, AA-derived epoxy-metabolites, 14(15)-EET, 11(12)-EET and 5(6)-EET, were increased in cortex (13 to 55-fold; $p < 0.01$), hippocampus (41 to 104-fold; $p < 0.05$), cerebellum (18 to 52-fold; $p < 0.05$) and brainstem (19 to 22-fold; $p < 0.001$) of the ischemic CO$_2$-group. Mono-hydroxylated AA-derived metabolites, 5-, 11-, 12-, 15- and 20-HETE, were increased in cortex (10 to 345-fold; $p < 0.05$), hippocampus (4 to 67-fold; $p < 0.01$), cerebellum (3 to 204-fold; $p < 0.05$) and brainstem (2.5 to 372-fold; $p < 0.001$), following ischemia. 15-oxo-ETE, an AA-derived ketone, was increased by 11-fold in cortex ($p = 0.0067$), 7.4-fold in hippocampus ($p < 0.0001$), 4.7-fold in cerebellum ($p = 0.03$) and 5.2-fold in brainstem ($p < 0.0001$), while 5-oxo-ETE was increased by 7.9-fold in cortex ($p = 0.039$) and 5.3-fold in hippocampus ($p = 0.0099$), and 12-oxo-ETE by 12.9-fold in cortex ($p = 0.0061$) (Fig. 3).

Prostanoids (6-keto-PGF$_{1α}$, PGF$_{2α}$, PGE$_2$, PGD$_2$, PGI$_2$) were negligible or not detected in MW-fixed controls, but were present in the four brain regions of CO$_2$-treated rats ($p < 0.001$). Ischemia also increased the cortical
concentrations of epoxy- (8(9)-EpEtrE; \( p = 0.0048 \)), monohydroxy- (8- and 9- HETE; \( p < 0.05 \)), dihydroxy-
(14,15- and 11,12-DiHETE, \( p < 0.001 \); 8,15- and 5,15-DiHETE, \( p < 0.01 \)) and trihydroxy- (11,12,15-TriHETE; \( p = 0.0012 \)) AA metabolites, which were not detected in MW-fixed controls (Fig. 3).

Ischemia increased DHA-derived metabolites in various brain regions. DHA-derived epoxy-metabolites (19(20)-, 16(17)-, 13(14)-, 10(11)- and 7(8)-EpDPE) were higher in cortex (3.9 to 7.3-fold; \( p < 0.01 \)), hippocampus (9 to 12.7-fold; \( p < 0.01 \)), cerebellum (4.8 to 7.9-fold; \( p < 0.01 \)) and brainstem (6.6 to 9.4-fold; \( p < 0.01 \)) of ischemic rats compared to MW-fixed controls (Fig. 4). 17-HDoHE was detected in cortex and cerebellum (\( p < 0.01 \)) of ischemic CO₂-treated rats but not MW-fixed controls, and was 8.1- and 7.4-fold higher in hippocampus (\( p = 0.025 \)) and brainstem (\( p = 0.0072 \)) of ischemic rats, respectively, relative to controls. Amongst the dihydroxy DHA metabolites analyzed, only 19,20-DiHDPE increased by 2-fold in hippocampus of the ischemic CO₂-group compared to MW-fixed controls (\( p = 0.021 \)).

Other fatty acid metabolites found in relatively low concentrations in control brains were increased following ischemia. The concentrations of DGLA, ALA and EPA-derived metabolites within the different brain regions were low and only few of them were detected (Fig. 5). DGLA-derived PGD\(_2\) and 15(S)-HETE, were present in all brain regions of the ischemic CO\(_2\)-group but were absent or negligible in the MW-fixed group (\( p < 0.01 \)). ALA-derived 15,16-DiHODE was 2.3 and 1.9 times higher in cortex (\( p = 0.0314 \)) and cerebellum (\( p = 0.0028 \)) of ischemic rats compared to MW-fixed controls, respectively. ALA-derived 13-HOTrE increased by 1.9 fold in brainstem (\( p = 0.0078 \)). EPA-derived 11(12)-EpETE was detected in hippocampus following ischemia, but not in controls. Other detected EPA-derived metabolites did not significantly differ between the groups.

13-HODE and PGE\(_{2\gamma}\) but not their fatty acid precursors, increased somatic PPF. Hippocampal extracellular recordings were performed to test whether 13-HODE, the main LA metabolite detected in hippocampus (Fig. 2), altered neurotransmission in a manner comparable to its precursor, LA, and to AA and AA-derived PGE\(_2\).

Two-way repeated measures ANOVA revealed a significant effect of time (\( p < 0.0001 \)), and time-compound interaction (\( p < 0.0001 \)) on the minute-by-minute PPF in soma. As indicated in Fig. 6a, compared to vehicle,
0.1 µM PGE₂ significantly increased somatic PPF during the washout period (at 24, 25, 26 and after 28 minutes of recording; \( p < 0.05 \) by Dunnett’s post-hoc test). Mean somatic PPF was also significantly altered by time (\( p = 0.0003 \)), compound (\( p = 0.0287 \)) and time-compound interaction (\( p = 0.0121 \)), as evidenced by the significant 1.8-fold and 2.4-fold increase in somatic PPF by 0.1 µM 13-HODE (\( p = 0.0296 \)) and 0.1 µM PGE₂ (\( p < 0.0001 \)) during the washout period (Fig. 6b). No significant effects of time or treatment were observed in dendritic PPF (Fig. 6c and 6d).

Gas-chromatography analysis confirmed the purity of LA and AA stock solutions to be 96.6% and 91.7%, respectively. AA contained a small amount of palmitic acid (C16:0; 1.3%), oleic acid (C18:1 n-9; 1.0%) and LA (0.3%). LC-MS/MS analysis showed that 13-HODE and PGE₂ were 98–99% pure in the stock solution. LC-MS/MS analysis of artificial cerebrospinal fluid (ACSF) aliquots obtained at the end of the 10-minute perfusion was also performed to test whether the fatty acids or oxylipins were degraded during their incubation in ACSF at 37 °C under constant bubbling of 95% oxygen. As shown in Fig. 7, AA and LA did not degrade into any of the measured oxylipins, although this does not preclude the possibility of degradation into other compounds not covered by our lipidomic assay such as AA-derived F2-isoprostanes. ACSF aliquots of 13-HODE were >99% pure. PGE₂, however, contained 20% PGE₂ and 78% PGD₂, suggesting degradation of the PGE₂ into PGD₂ during the 10-minute perfusion period.

**Discussion**

Here, we provide new evidence that LA is involved in the response to ischemia-induced brain injury and the regulation of neurotransmission through its oxidized metabolites. Ischemia increased cortex, cerebellum, hippocampus and brainstem LA-derived oxylipin concentrations, of which 13-HODE was tested and found to increase somatic PPF in hippocampus similar to AA-derived PGE₂. The results suggest that during ischemic brain injury, the brain actively produces LA-metabolites that regulate neuronal signaling.

The present study confirmed previous reports of increased AA-derived prostaglandins (in particular PGE₂ and PGD₂), thromboxane B2 and lipoygenase products (HETE, o xo-ETE and leukotrienes) \(^{41, 46, 47, 56, 70}\), and increased DHA-derived 17-HDoHE\(^{45, 49}\) in hippocampus or whole brain of rodents subjected to hypoxic or ischemic brain injury. By incorporating an expanded AA and DHA oxylipin panel in our LC-MS/MS platform, we also found an increase in epoxidized metabolites of AA and DHA following ischemia in cortex, hippocampus, cerebellum
and brainstem. Because AA- and DHA-derived epoxides are anti-inflammatory and neuroprotective\textsuperscript{71–74}, their increase following ischemia likely represents an adaptive response to prevent ischemia-related brain injury.

The parallel increase in LA metabolites in cortex, hippocampus, cerebellum and brainstem suggests that LA oxidized products are also involved in the response to ischemic brain injury, consistent with one study that reported increased 9- and 13-HODE in cortex of dogs subjected to 10-minutes of ischemic cardiac arrest\textsuperscript{75}. CYP-derived LA epoxides (9(10)- and 12(13)-EpOME) were increased in hippocampus and cerebellum, two brain regions sensitive to hypoxic and ischemic insults\textsuperscript{58–61}, whereas LOX-derived 9- and 13-HODE and oxo-ODE were increased in cortex and the brainstem. This reflects the selective synthesis of LA-derived species that likely play diverse roles during ischemia.

Many oxylipins produced following brain injury (prostanoids or epoxides) are known to regulate neurotransmission coupled to physiological processes that promote vasodilation or reduce excitotoxicity\textsuperscript{48, 49, 76}. In the present study, we tested whether LA-derived 13-HODE also regulated neurotransmission. 13-HODE at 0.1 µM increased somatic but not dendritic paired-pulse facilitation in hippocampus, suggesting its involvement in regulating post-synaptic transmission and consistent with the somato-dendritic localization of COX and LOX enzymes that rapidly synthesize it\textsuperscript{77}. 13-HODE was found to block phospholipase C-induced activation of protein kinase C\textsuperscript{78}, a key regulator of short-term plasticity\textsuperscript{79}. The mechanism of action of 13-HODE may involve a G-protein coupled receptor, such as the G2A receptor which binds oxidized fatty acid metabolites\textsuperscript{80}. Identifying the specific G-protein receptor(s) that selectively binds 13-HODE in future studies might elucidate the mechanisms by which 13-HODE regulates neurotransmission in response to ischemic brain injury. Confirming that 13-HODE also regulates neurotransmission in cortex and brainstem, two brain regions were 13-HODE increased during ischemia, will inform on whether 13-HODE acts globally or on specific brain regions.

13-HODE and PGE\textsubscript{2} increased somatic PPF at 0.1 µM but not 1 µM. The 0.1 µM dose of 13-HODE and PGE\textsubscript{2} is consistent with the amount found in brain (based on measured concentrations in Figs 2 and 3 corrected for brain density), thus being physiologically relevant. Hippocampal dendritic PPF was reported to decrease by 5 µM\textsuperscript{67, 68} or remain unchanged by 0.5 µM\textsuperscript{69} or 10 µM\textsuperscript{69} PGE\textsubscript{2}, respectively. We are not aware of studies that specifically explored the effects of PGE\textsubscript{2} on somatic transmission. However, by quantifying PGE\textsubscript{2} (and 13-HODE) in hippocampus, this study demonstrated the signaling effects of both compounds at physiologically relevant concentrations and showed that higher doses were ineffective. Unesterified LA and AA did not alter PPF when applied at a physiologically relevant concentration of 1 µM\textsuperscript{82}, suggesting that their signaling effects in brain are likely mediated by their metabolites.
Approximately 78% of the PGE\(_2\) was converted to PGD\(_2\) in the ACSF chamber, before reaching the slice. This means that the observed changes in hippocampal PPF in this study and possibly others\(^{67-69}\) could be mediated by PGD\(_2\). Little is known about the role of PGD\(_2\) on hippocampal neurotransmission. Chen \textit{et al.}\(^{83}\) reported that 0.33 µM PGD\(_2\) did not alter postsynaptic excitability and induction of long-term potentiation in the presence of a COX-2 inhibitor, suggesting it likely has limited effects on neuronal excitability\(^{83}\).

Regional increases in brain EPA-derived 11,12-EpETE and 17,18-diHETE, ALA-derived 13-HoTrE and DGLA-derived PGD\(_1\) and 15(S)-HETrE were also seen following ischemia. DGLA-, ALA- and EPA-derived metabolites have been reported to reduce inflammation \textit{in vitro}\(^8\) and \textit{in vivo}\(^8\)\textsuperscript{84-87}, although their role in regulating neurotransmission or the response to brain injury is not known. The observed increase in their concentrations following ischemia highlights the need to explore their neurophysiological role and bioactivity in future studies.

In summary, this study showed that LA participates in the response to ischemic brain injury through metabolites that also regulate neurotransmission. Targeting this pathway using low LA diets\(^8,31\) or novel drugs may be therapeutically useful for ischemia-related conditions such as stroke or hypoxic-ischemic encephalopathy of newborn infants.

**Methods**

**Animals.** All procedures were performed in agreement with the policies of the Canadian Council on Animal Care and were approved by the Animal Ethics Committee of the University of Toronto and University Health Network. Thirty to thirty-four day old male rats were purchased from Charles River (Saint-Constant, QC, Canada). Upon their arrival, rats were housed in pairs and fed for 30 days with a Harlan Teklad 2018 diet containing 18.6% protein, 6.2% fat, 58.9% carbohydrate, 3.5% crude fiber and 5.3% ash and 7.5% moisture. The diet contained (% of total fatty acids), 18.5% palmitic acid (16:0), 2.8% stearic acid (18:0), 18.5% oleic acid (18:1 n-9), 54.8% LA and 5.6% ALA\(^{88}\).

**Rat tissue collection.** Rats were subjected to head-focused microwave (13.5 kW for 1.6 s; MW-fixed control group; \(n = 9\)) or CO\(_2\) asphyxiation for 2 min (CO\(_2\)-group; \(n = 9\))\(^{89}\). Brains were rapidly removed following head decapitation and separated into cortex, cerebellum, hippocampus and brainstem on ice. The use of CO\(_2\) causes hypercapnia, which is followed by decapitation-induced ischemia. The effects of hypercapnia on measured
Oxylipins are minimal compared to that of ischemia, which is why the effects reported in this study will be linked to ischemia rather than the combined effect of hypercapnia and ischemia. Samples were stored at −80 °C for approximately one month until they were shipped on dry ice from Toronto, ON, Canada to Davis, CA, USA, where they were stored in a −80 °C freezer until use.

**Oxylipin extraction by solid phase extraction (SPE).** Oxylipins were extracted from the different cerebral regions by solid phase extraction (SPE), as previously described. Two to four hundred µL of ice-cold extraction solvent (0.1% acetic acid and 0.1% butylated hydroxytoluene (BHT) in methanol) was added to frozen cortex (average weight >200 mg; 400 µL of extraction solvent), hippocampus, cerebellum and brainstem (weight <200 mg; 200 µL of extraction solvent), followed by the addition of 10 µL of antioxidant mix and 10–20 µL surrogate standard solution. The antioxidant solution containing 0.2 mg/mL of BHT, triphenylphosphine (TPP) and ethylenediaminetetraacetic acid (EDTA) in methanol/water (50/50, v/v) was filtered through a Millipore filter (Millipore, Bedford, MA, USA) prior to use. The surrogate standard solution contained 500 nM of d11-11(12)-EpETE, d11-14,15-DiHETE, d4-6-keto-PGF1α, d4-9-HODE, d4-LTB4, d4-PGE2, d4-TXB2, d6-20-HETE and d8-5-HETE in methanol, and was added at an amount of 5–10 pmol per sample.

Frozen pre-weighed samples were homogenized for 5 to 10 min at 30 vibrations per second with a bead homogenizer. After storage overnight in a −80 °C freezer, samples were centrifuged at 13,200 rpm for 10 min at 4 °C. Two hundred µL of supernatant were added to a 60 mg Waters Oasis HLB 3cc cartridges (Waters, Milford, MA, USA) prior to use. The surrogate standard solution contained 500 nM of d11-11(12)-EpETE, d11-14,15-DiHETE, d4-6-keto-PGF1α, d4-9-HODE, d4-LTB4, d4-PGE2, d4-TXB2, d6-20-HETE and d8-5-HETE in methanol, and was added at an amount of 5–10 pmol per sample.

Figure 6. Somatic (a and b) and dendritic (c and d) Paired-Pulse Facilitation (PPF) measured on hippocampal slices perfused with vehicle (artificial cerebrospinal fluid containing 0.1% ethanol), 1 µM linoleic acid (LA), 1 µM arachidonic acid (AA), 0.1 µM or 1 µM 13-hydroxyoctadecadienoic acid (13-HODE), or 0.1 µM or 1 µM prostaglandin E2 (PGE2). Data (mean ± SD) are expressed relative to baseline (n = 4–6 per condition). Graphs (a and c) show the minute-by-minute data; (b and d) represent average PPF during compound incubation and washout relative to baseline (dotted line). Data were analyzed by a two-way repeated measures ANOVA followed by Dunnett’s multiple comparison test. *Significantly different compared to vehicle at a specific time point.
Samples were dried in a Speed-Vac®, reconstituted in 50 µL methanol containing 200 nM 1-cyclohexyl ureido, 3-dodecanoic acid (CUDA) as a recovery standard and filtered by centrifugation using Ultrafree-MC-VV polyvinylidene fluoride filters (0.1 µm; Millipore, Bedford, MA, USA).

**Oxylipin analysis by liquid chromatography tandem mass spectrometry (LC-MS/MS).** The PUFA-derived oxylipin analytical platform included 85 oxylipins (Supplementary Table 1) derived from omega-6 LA, LAs elongation-desaturation products DGLA and AA, and omega-3 ALA, EPA and DHA. Oxylipins were

**Figure 7.** Dynamic multiple reaction monitoring scan of oxidized fatty acids in artificial cerebrospinal fluid (ACSF) containing vehicle, 1 µM linoleic acid (LA), 1 µM arachidonic acid (AA), 1 µM 13-hydroxyoctadecadienoic acid (13-HODE), or 1 µM prostaglandin E₂ (PGE₂). The vehicle or compounds were incubated in ACSF at 37 °C for 10 min under constant bubbling of 95% O₂. No contamination was observed in vehicle and ACSF containing LA and AA. ACSF containing 13-HODE was pure at >98%. ACSF containing PGE₂ had 20% PGE₂, 78% PGD₂ and 2% unidentified impurities. As shown in the figure, PGE₂ and PGD₂ peaks eluted at the same time.
analyzed by ultra-high pressure liquid chromatography tandem mass spectrometry UPLC-MS/MS as previously described on an Agilent 1200SL (Agilent Corporation, Palo Alto, CA, USA) UPLC system connected to a 4000 QTRAP tandem mass spectrometer (Applied Biosystems Instrument Corporation, Foster, CA, USA) equipped with an electrospray ion source (Turbo V). Oxylipins were separated on an Agilent 2.1 × 150 mm Eclipse Plus C18 column with a 1.8 μm particle size. Standards obtained from Larodan (Solna, Sweden), Cayman Chemicals (Ann Arbor, MI, USA) or synthesized by Dr. Hammock's laboratory were used for calibration curves for each oxylipin.

The autosampler temperature was kept at 4°C and the column at 50°C. The mobile phase A contained 0.1% acetic acid in ultrapure water and the mobile phase B contained acetonitrile/methanol/acetic acid (84/16/0.1). Gradient elution was performed at a flow rate of 0.25 mL/min for a total run time of 21 min as follows: solvent B was held at 35% for 0.25 min, increased to 45% from 0.25 to 1 min, to 55% B from 1 to 3 min, to 65% B from 3 to 8.5 min, to 72% from 8.5 to 12.5 min, to 82% B from 12.5 to 15 min, to 95% B from 15 to 16.5 min, held at 95% for 1.5 min, decreased from 35% to 18% and held at 35% for 2.9 min. The instrument was operated in negative electrospay ionization mode and used optimized multiple reaction monitoring (MRM) conditions of the parent and fragmentation product ion to target each oxylipin. Peaks were quantified according to the standard curves and corrected for the surrogate standard recovery using Analyst Software 1.4.2.

The limit of quantification (LOQ) was set to three times the lowest standard concentration used in the standard curve. Oxylipins with >30% of values below the LOQ were excluded from the statistical analysis.

**Preparation of the artificial cerebrospinal fluid (ACSF) solutions.** A low Na⁺/Ca²⁺ ACSF containing 50 mM NaCl, 160 mM sucrose, 3.5 mM KCl, 2 mM NaH₂PO₄, 0.5 mM CaCl₂, 2 mM MgCl₂, 7 mM glucose and 5 mM HEPEES (pH adjusted to 7.4) was prepared and used during intracardial perfusion and the slice preparation to limit excitotoxicity. A standard ACSF containing 3.5 mM KCl, 1.25 mM NaH₂PO₄, 125 mM NaCl, 25 mM NaHCO₃, 10 mM glucose, 2 mM CaCl₂ and 1.3 mM MgSO₄ (pH 7.4 when aerated with 95% O₂–5% CO₂) was used during the hippocampal slice perfusion and electrophysiology recordings.

**Slice preparation.** Experiments were performed on 400-μm-thick hippocampal slices from 62- to 74-d-old male Long Evans rats (Charles River Laboratory, Quebec, Canada). Rats were euthanized with a lethal dose of sodium pentobarbital (70 mg/kg) and intracardially perfused with cold low Na⁺/Ca²⁺ ACSF. After decapitation, the brain was rapidly removed and maintained in ice-cold oxygenated (95% O₂–5% CO₂) low Na⁺/Ca²⁺ ACSF for a few minutes. The brain was hemi-sectioned and the hippocampus isolated and glued onto an aluminum block. Four hundred-μm-thick transverse hippocampal slices were obtained using a vibrotome and then placed in the standard ACSF at room temperature for at least 1 h before recordings.

**Extracellular recordings.** Extracellular recordings were used to test the isolated effect of each compound on paired-pulse facilitation. Extracellular recordings were obtained from 4 to 6 slices per fatty acid or oxylipin treatment. Slices were transferred to a submerged recording chamber and continuously perfused with warm (37°C) oxygenated ACSF. After decapitation, the brain was rapidly removed and maintained in ice-cold oxygenated (95% O₂–5% CO₂) low Na⁺/Ca²⁺ ACSF for a few minutes. The brain was hemi-sectioned and the hippocampus isolated and glued onto an aluminum block. Four hundred-μm-thick transverse hippocampal slices were obtained using a vibrotome and then placed in the standard ACSF at room temperature for at least 1 h before recordings.

**Compounds.** 13-HODE and PGE₂ were purchased from Cayman Chemicals (Ann Arbor, Michigan, USA). LA and AA were purchase from Nuchek Prep, Inc. (Elysian, MN, USA). The different drugs were dissolved in ethanol (stock concentration at 1 mM or 0.1 mM) and diluted 1000 times in ACSF to 1 μM LA, 1 μM AA, 0.1 μM or 1 μM 13-HODE, and 0.1 μM or 1 μM PGE₂. Vehicle was made by diluting 100 μL of pure ethanol per 100 mL ACSF. The final ethanol concentration for vehicle or compounds was kept at or below 0.1%. The fatty acid precursors, LA and AA, were tested at 1 μM to mimic physiological conditions, because brain unesterified LA and AA concentrations in rodents range between 1–3 nmol/g, which corresponds to 0.96–2.88 μM, based on a rat brain density of 1.04–1.05 g/mL.

In an exploratory manner, we also tested the effects of AA-derived 14(15)-EET synthetized to 99% purity, at 1 μM and of LA-derived 9-oxo-ODE at 0.1 μM (Cayman Chemicals). We had intended to test lower concentrations of 14(15)-EET, but by testing the dose of 1 μM, we ran out of the compound and were not able to perform tests at 0.1 μM. Pilot data related to the effects of 14(15)-EET on PPF are provided in Supplementary Figure 2. As shown, 14,15-EET significantly reduced dendritic PPF during the washout period. The 9-oxo-ODE data were not included because LC-MS/MS analysis revealed that the stock solution was impure and contained 80% 9-oxo-ODE, 11% 5,6-DiHETE and 9% EPA. Regardless, no significant changes in somatic or dendritic PPF were observed with 9-oxo-ODE.
The purity of the stock LA and AA was determined by gas-chromatography (GC), whereas that of 13-HODE, PGE$_2$, and 14,15- EET was measured by LC-MS/MS. An 1 ml aliquot of ACSF containing the metabolites was obtained at the end of the 10-minute perfusion to determine whether the compounds were modified by being maintained at 37°C in oxygenated ACSF (95% O$_2$, 5% CO$_2$, for 10 minutes). The purity of the compounds was measured on an Agilent 1290 Infinity UHPLC system coupled to a 6460 triple-quadrupole tandem mass spectrometer with electrospray ionization (Agilent Corporation, Palo Alto, CA, USA). The system used optimized multiple reaction monitoring (MRM) conditions and was operated in negative electrospray ionization mode. Oxylipins were separated on an Agilent Eclipse Plus C-18 reverse-phase column (2.1 x 150 mm, 1.8 µm particle size). The auto-sampler temperature was kept at 4°C and the column at 45°C. Mobile phase A contained ultrapure water with 0.1% acetic acid. Mobile phase B contained acetonitrile/methanol (80/15 v/v) with 0.1% acetic acid. The flow rate started at 0.3 mL/min, decreased to 0.2 mL/min between 6 and 6.1 min, held at 0.2 mL/min for 24.4 min, increased to 0.35 mL/min between 30.5 and 30.6 min, held at 0.35 mL/min for 2.1 min, and decreased to 0.3 mL/min between 32.7 and 34 min. The following elution gradient was applied: mobile phase B was held at 40% for 6 min, increased to 80% from 6.1 to 20 min, increased to 99% from 30.5 to 30.6 min, held at 99% for 2 min, decreased to 40% between 32.6 and 32.7 min and held at 40% for 1.3 min. Peaks were analyzed using Agilent Mass Hunter Workstation Software Quantitative Analysis for QQQ (Version B.07.00). The oxylipin panel assayed included 72 available compounds from Cayman Chemicals and Larodan. The panel included all compounds listed in Supplementary Table 1, less the following: THF diols, 19,20-DiHDPE, 16,17-DiHDPE, 13,14-DiHDPE, 10,11-DiHDPE, 7,8-DiHDPE, 4,5-DiHDPE, 11,12-DiHETE, 8,9-DiHETE, 11,12,15- TriHETErE and LTB5. It also included leukotrienes C4, D4 and E4.

Statistical analysis. Data were expressed as mean ± standard deviation (SD). Oxylipin extraction and analysis, as well as the analysis of extracellular recordings were performed by blinded individuals.

Differences between the CO$_2$-group and MW-fixed controls were assessed using an unpaired t-test (GraphPad Prism 6.0, GraphPad Software Inc., San Diego, CA, USA). The final sample size per group was between 7 and 9, because the surrogate standard peak could not be accurately integrated for some of the samples. Heat maps were generated using MetaboAnalyst 3.0.$^{94,95}$

Somatic and dendritic PPF were expressed relative to the average baseline per slice. Absolute PPF data are presented in Supplementary Table 2. The effect of time and test compound on the normalized somatic and dendritic PPF were evaluated with a two-way repeated measures ANOVA (GraphPad Prism 6.0, GraphPad Software Inc., San Diego, CA, USA). When a significant interaction was found, Dunnett’s multiple comparison test was performed to evaluate for each time point the effect of the test compound compared to vehicle. The analysis was performed on the minute-by-minute data, as well as on the average data per period (baseline – compound – washout).

Statistical significance was set at $p < 0.05$.

Acknowledgements
This study was funded by UC Davis Food Science Department and College of Agriculture and Environmental Sciences (A.Y.T.) and by the Natural Sciences and Engineering Research Council of Canada (grant #482597 to R.P.B., grant # RGPIN-2015-04153 to L.Z.) and Eplink Program for Ontario Brain Institute. R.P.B. holds a Canada Research Chair in Brain Lipid Metabolism. Partial support was provided by NIEHS R01 ES002710, Rapid Assays for Human and Environmental Exposure Assessment, and NIEHS Superfund Research Program P42 ES004699 (to B.D.H.). K.S.S.L. is partially supported by the N.I.H. Pathway to Independence Award (R00 ES024806). The authors thank Dr. Michael Leadley from the analytical Facility for Bioactive Molecules Research Institute at the Hospital for Sick Children (Toronto, ON, Canada) for running the assays confirming the purity of the stock standard solutions.

Author Contributions
A.Y.T., R.P.B. and L.Z. conceived the experiments. A.Y.T., A.M., A.K. and L.Z. conducted the experiments. M.H., Y.O. and C.E.R. performed the oxylipin extraction. M.H., Y.O., S.K.L. and J.Y. performed the LC-MS/MS analysis. J.Y. and B.D.H. developed the LC-MS/MS oxylipin method. S.K.L. synthetized and purified the 14,15-EET for electrophysiological recordings. M.H. analyzed the LC-MS/MS data. M.H. and Z.Z. performed the electrophysiology analysis. All authors reviewed and approved the manuscript.
