ABSTRACT
Polyethylene glycol (PEG) functionalized double-walled carbon nanotubes (DWNTs) have been synthesized by a [2 + 1] cycloaddition reaction and characterized by transmission electron microscopy, atomic force microscopy, Raman spectroscopy, thermal gravimetric analysis, and UV–visible spectroscopy. Functionalization affords a large increase in the aqueous solubility of DWNTs. The saturated concentrations of DWNTs functionalized with diazido-terminated PEG800 (with a molecular weight of 800) and azido-terminated PEG750 monomethylether (with a molecular weight of 750) are very similar—0.36 and 0.37 mg/mL (DWNTs equivalent concentration), respectively.

KEYWORDS
Double-walled carbon nanotubes (DWNTs), functionalization, polyethylene glycol (PEG), water soluble

Introduction
Because of their novel structure and electronic properties, double-walled carbon nanotubes (DWNTs) have attracted particular attention during the past few years. Many potential applications in various fields have been explored, such as field-effect transistors, atomic force microscope (AFM) tips, filaments, energy conversion materials, and resistors [1–5].

However, like single-walled carbon nanotubes (SWNTs), their insolubility in most common solvents severely impedes the manipulation and application of DWNTs. Functionalization is a common method to solve this problem, but there have only been a few previous studies directed at DWNTs. The first example involved the covalent attachment of fluorine atoms to DWNTs [6]. Later, the reaction of DWNTs with lysine was reported [7]. However, neither of these papers mentioned the solubility of the product. Very recently, DWNTs were covalently modified with azobis-type radical initiators but the resulting product could only be well dispersed in methanol [8].

Polymers play an important role in the functionalization of carbon nanotubes, especially SWNTs, because the polymer chains may help the nanotubes dissolve efficiently in solvents and can also enhance dispersion of the nanotube bundles. One important and feasible route is sidewall functionalization via
reactions with a variety of reactive molecules [9–12]. Supposing DWNTs and SWNTs have similar chemical properties, addition of polymers with azido end groups might be a good choice for modification and dispersion of DWNTs.

Herein, we present the functionalization of DWNTs with two kinds of polyethylene glycol (PEG) azides [diazido-terminated PEG and azido-terminated monomethylether] by [2+1] cycloaddition. Both PEG molecules endow DWNTs with good solubility in water.

1. Experimental

DWNTs were synthesized by the arc discharge method [13] and purified following the protocol in reference [13]. Briefly, after oxidation in air at 400 °C for 1 h, DWNTs were refluxed in 15% H2O2 for 2 h, 6 mol/L HCl for 12 h, and 2.6 mol/L HNO3 for 12 h in turn. The mixture was filtered and the sediment was annealed in air at 600 °C for 1 h to obtain the purified DWNTs (p-DWNTs). Then, p-DWNTs were sonicated (96 W, Bandelin) for 6 h in HNO3/H2SO4 (v:v = 1:3). The acid treated DWNTs (t-DWNTs) were collected on a 0.45-μm polycarbonate membrane and washed with deionized water until the eluate acidity reached neutral. t-DWNTs were dried under vacuum at 60 °C.

PEG800 azide (diazido-terminated PEG with a molecular weight of 800) and CH3O-PEG750 azide (azido-terminated PEG monomethylether with a molecular weight of 750) were synthesized following Ref. [14]. 100 mg of t-DWNTs was dispersed in 100 mL of N,N-dimethylformamide (DMF) (which was distilled under reduced pressure with CaSO4 before use) under a nitrogen atmosphere by sonication for about 2 h. Then, the suspension was heated to 160 °C. 1 g of PEG800 azide was first dispersed in 30 mL of DMF by sonication and then added dropwise to the suspension of DWNTs at 160 °C. The mixture was stirred and refluxed at 160 °C for 15 h. After the reaction, the solvent was removed by distillation and the resulting product, PEG800 functionalized DWNTs (PEG800-DWNTs), was washed several times with ethanol to eliminate the free PEG800 residue. PEG800–DWNTs precipitated in ethanol was collected by centrifugation. The same procedure was adopted for the reaction between CH3O-PEG750 azide and t-DWNTs, and the final product is denoted CH3O-PEG750–DWNTs.

PEG–DWNTs were characterized by thermal gravimetric analysis (TGA), Raman spectroscopy, transmission electron microscopy (TEM), atomic force microscopy (AFM), and UV–visible spectroscopy. TGA was performed on a TA instrument Q600 SDT. Raman spectroscopy was performed on a JY Raman microscope (HR 800, France). The morphology of DWNTs was characterized by TEM (JEOL JEM-200 CX, Japan), high-resolution TEM (HRTEM) (JEOL JEM-7401, Japan), and AFM (Shimadzu SPM-9600, Japan). UV–visible spectra were recorded on a Lambda 35 spectrometer (PE, USA). X-ray photoelectron spectroscopy (XPS) spectra were recorded on an AXIS Ultra imaging photoelectron spectrometer (Kratos, Britain).

In order to obtain the saturated concentration of PEG–DWNTs in water, a certain amount of the sample was dispersed in water by sonication for 10 min, and then centrifuged at 3000 r/min to remove any solid residue. The resulting suspension was concentrated slowly until solid appeared. After discarding the solid, the supernatant (the saturated suspension) was collected, dried, and weighed. The saturated concentration of PEG800–DWNTs and CH3O-PEG750–DWNTs at room temperature was thus obtained.

2. Results and discussion

Figure 1 shows TEM images of p-DWNTs and t-DWNTs. p-DWNTs with a length of 5–10 μm existed in large bundles. We failed to modify p-DWNTs with the functionalized PEG molecules. The poor dispersion properties of p-DWNTs may account for this failure. Compared with p-DWNTs, t-DWNTs are easier to disperse in solvents, and when p-DWNTs were replaced by t-DWNTs the PEGylation reaction succeeded. The t-DWNTs were prepared by sonication of p-DWNTs in a mixed acid which causes less damage to DWNTs, and therefore better retains their intrinsic properties, than refluxing in the mixed acid. The final PEG800–DWNTs and CH3O-PEG750–DWNTs both possessed reasonable solubilities in water, forming stable dark-brown solutions.
Scheme 1 shows the reactions of $t$-DWNTs with PEG$_{800}$ azide or CH$_3$O-PEG$_{750}$ azide. We assume the reaction mechanism of the functionalization of DWNTs by the PEG azides is similar to that of the covalent functionalization of SWNTs with nitrenes [9–11]. Nitrenes contain a monovalent active nitrogen atom surrounded by a sextet of electrons. An azide can easily convert to a reactive nitrone in situ after thermally induced extrusion of N$_2$. The nitrene may be either a singlet state (having two filled $p$-orbitals) or a triplet state (having one filled $p$-orbital and two $p$-orbitals containing unpaired electrons). Both of these can attack the nanotube sidewall to afford aziridine rings, by an electrophilic $[2 + 1]$ cycloaddition and a reaction between biradicals and the $\pi$-system of the nanotube sidewalls, respectively [9, 11]. PEG$_{800}$ azide has two azide groups, and therefore results in cross-linked

**Figure 1** Representative TEM images of $p$-DWNTs and $t$-DWNTs: (a) low-resolution TEM image of $p$-DWNTs, (b) HRTEM image of $p$-DWNTs, (c) low-resolution TEM image of $t$-DWNTs, (d) HRTEM image of $t$-DWNTs

**Scheme 1** The functionalization of $t$-DWNTs with PEG azides by $[2 + 1]$ cycloaddition
nanotubes in PEG\textsubscript{800}–DWNTs, whereas the reaction of CH\textsubscript{3}O–PEG\textsubscript{750} azide with DWNTs does not produce cross-linked nanotubes (Scheme 1).

PEG\textsubscript{800}–DWNTs and CH\textsubscript{3}O–PEG\textsubscript{750}–DWNTs can be seen clearly by TEM (Figs. 2(b) and 2(d)). In Fig. 2(a), the height profile of the nanotube is 2–5 nm, corresponding to the diameter of a typical individual DWNT. This confirms the presence of individual DWNT in CH\textsubscript{3}O–PEG\textsubscript{750}–DWNTs. The AFM images of PEG\textsubscript{800}–DWNTs give a height of 7.0–8.5 nm, indicating that small bundles of DWNTs are present.

Raman spectroscopy has been used to characterize the structure of DWNTs [13, 15, 16]. Figure 3 shows the Raman spectra of the four DWNT samples excited by a 532-nm laser. We observe an intense peak at \( \sim 1578 \text{ cm}^{-1} \) (G band), a weaker peak at \( \sim 1347 \text{ cm}^{-1} \) (D band), the second order G’ band at \( \sim 2712 \text{ cm}^{-1} \), and a broad peak below 200 cm\(^{-1}\), which are all characteristic Raman signals of DWNTs. The peak below 200 cm\(^{-1}\) is the radial breathing mode (RBM) of DWNTs, the frequency of which \( (\omega_r) \) is inversely proportional to the inner diameter \( (d) \) of the DWNTs according to the equation \( \omega_r = 6.5 + 223.75/d \) [13, 15]. The Raman shifts and the corresponding nanotube diameters are listed in Table S-1 in the Electronic Supplementary Material (ESM). The outer and inner diameters of t-DWNTs and p-DWNTs are in the ranges 2.02–3.56 nm and 1.26–2.80 nm, respectively. The ratios of the intensity of the G and D bands \( (I_G/I_D) \) for p-DWNTs and t-DWNTs are 7.3 and 3.5, respectively. Acid treatment results in an increase in the number of defects in the nanotube lattice, and therefore the D band intensity increases. After functionalization, the \( I_G/I_D \) ratios of DWNTs decrease from 3.5 to 2.9 for PEG\textsubscript{800}–DWNTs.
Figure 3  Raman spectra of PEG$_{800}$–DWNTs (red), CH$_3$O-PEG$_{750}$–DWNTs (black), $p$-DWNTs (blue), and $t$-DWNTs (green) excited by a 532-nm laser. The G band intensity is set as 100% and the Raman spectra are normalized accordingly and to 2.3 for CH$_3$O-PEG$_{750}$–DWNTs, respectively. The decrease in the $I_G/I_D$ ratio and the increase in the G bandwidth after functionalization indicate a further increase in the number of defects in the nanotube lattice. This is due to the introduction of covalently bound moieties to the nanotube framework.

To evaluate the amount of polymer grafted to DWNT, TGA was performed from room temperature to 600 °C in an atmosphere of nitrogen (Fig. 4). Between 100 and 250 °C, the $p$-DWNTs sample showed no weight loss, while $t$-DWNTs underwent about 5% weight loss that could be attributed to the detachment of carbonyl groups and loss of adsorbed water. TGA analysis indicated that the weight losses for PEG$_{800}$ and PEG$_{750}$ monomethylether occurred from 250 to 400 °C (Fig. 4). For both PEG$_{800}$–DWNTs and CH$_3$O-PEG$_{750}$–DWNTs, there are two obvious processes of weight loss in their TGA curves: one occurs at temperatures less than 250 °C, similar to that for $t$-DWNTs, and the other is between 250 and 400 °C, which matches the temperature range for PEG decomposition. The TGA data therefore suggest that PEGylation does not occur at the defective sites of the nanotube surface.

Since the decomposition of PEG$_{800}$ and PEG$_{750}$ monomethylether occurs between 250 and 400 °C (Fig. 4), the weight loss difference between PEG–DWNTs and $t$-DWNTs within this temperature range is a measure of the content of grafted polymer PEG.

According to Fig. 4, the content of PEG$_{800}$ in PEG$_{800}$–DWNTs is about 58 wt.%. This suggests that there is one PEG$_{800}$ attached for every 48 DWNT carbon atoms in PEG$_{800}$–DWNTs (see the ESM for details of the calculation), whilst the content of CH$_3$O-PEG$_{750}$ attached to DWNTs is about 60 wt.%, indicating one CH$_3$O-PEG$_{750}$ per 42 DWNT carbon atoms.

The resulting PEG–DWNTs have fairly good solubility in water. Figure 5 shows photographs of suspensions of various DWNT samples. Samples of PEG$_{800}$ and PEG$_{750}$ monomethylether just simply mixed with $t$-DWNTs are shown for comparison. The five samples were sonicated in water for 10 min. $t$-DWNTs could not be dispersed in water, therefore settled out immediately after sonication. The same
Figure 5 Photographs of various DWNTs in water: (a) t-DWNTs, (b) CH$_3$O-PEG$_{750}$–DWNTs, (c) PEG$_{800}$–DWNTs, (d) CH$_3$O-PEG$_{750}$/t-DWNTs mixture, (e) PEG$_{800}$/t-DWNTs mixture. Both PEG–DWNTs suspension samples are shown after standing undisturbed for three weeks.

Figure 6 UV–visible absorption spectra of PEG$_{800}$–DWNTs at different concentrations in water. Shown in the inset is the linear dependence of absorption on suspension concentration.

non-dispersion phenomenon was found for the CH$_3$O-PEG$_{750}$/t-DWNTs and PEG$_{800}$/t-DWNTs mixtures. However, the suspensions of both PEG–DWNTs were much more stable. After centrifugation at 3000 r/min for 10 min, both supernatants were a homogenous dark-brown color and remained stable for over three weeks without any discernible sedimentation. The saturated concentration of PEG$_{800}$–DWNTs was 0.86 mg/mL (corresponding to a DWNTs equivalent concentration of 0.36 mg/mL). The saturated concentration of CH$_3$O-PEG$_{750}$–DWNTs was 0.93 mg/mL, and its DWNTs equivalent concentration (0.37 mg/mL) is very close to that of PEG$_{800}$–DWNTs.

Figure 6 shows the UV–visible spectra of PEG$_{800}$–DWNTs in water. The intense peak of DWNTs at 265 nm is clearly observed. The absorbance of PEG$_{800}$–DWNTs is dependent on its concentration in a linear fashion (Fig. 6 inset), following the Beer–Lambert law. This further indicates that PEG$_{800}$–DWNTs form a homogeneous water suspension. Similar UV–visible profiles of CH$_3$O-PEG$_{750}$–DWNTs were obtained (data not shown).

In XPS analysis, the dominant C 1s peak at a binding energy of ca. 285 eV and O 1s peak at 533 eV were observed in all four samples (Fig. S-1 in the ESM). For the PEG–DWNTs samples, a weak signal for N 1s at 401 eV is detected. This indicates the presence of nitrogen–carbon bonds, resulting from the PEGylation of DWNTs. The lowest O/C ratio is obtained in the p-DWNTs sample (Table S-2 in the ESM). After acid treatment, the O/C ratio of t-DWNTs increases because of the presence of O-containing groups on the surface of the nanotubes. The O/C ratios of the PEGylated DWNTs are much higher than those of p-DWNTs and t-DWNTs, because of the PEG molecules grafted to DWNTs.

Functionalization with the PEG derivatives helps the manipulation and application of DWNTs by improving the solubility of DWNTs in solvents. To date, only a few reports of DWNTs have been published, and their solubility in aqueous solution was not mentioned [6–8]. Although refluxing in the mixed acids helps to disperse DWNTs in aqueous solutions, such a process produces many defects on the surface of DWNTs, probably leading to severe damage of the nanotubes. The PEGylation method we used here occurs on the intact surface of carbon nanotubes. Therefore, it yields less damage of the DWNTs and thus retains their intrinsic properties. PEGylation also obviously endows DWNTs not only with very good solubility and stability in water, but also stability in salt solutions, such as 0.9% NaCl. Finally, PEG molecules have very good biocompatibility. Thus, PEGylation makes applications of DWNTs in biological fields a real possibility.

3. Conclusions

We have demonstrated an efficient approach to functionalize DWNTs with two kinds of PEG azides
(PEG$_{800}$–DWNTs and CH$_3$O-PEG$_{750}$–DWNTs) using [2 + 1] cycloaddition. Both resulting PEG–DWNTs can be easily dispersed in water, forming highly stable suspensions. The resulting aqueous solubility (DWNTs equivalent concentration) of PEG$_{800}$–DWNTs is 0.36 mg/mL, whilst that of CH$_3$O-PEG$_{750}$–DWNTs 0.37 mg/mL. This new approach of functionalization will definitely be of benefit for the manipulation and application of DWNTs in the future.
