Interleukin-18 (Interferon-\(\gamma\)-inducing Factor) Is Produced by Osteoblasts and Acts Via Granulocyte/Macrophage Colony-stimulating Factor and Not Via Interferon-\(\gamma\) to Inhibit Osteoclast Formation

Summary

We have established by differential display polymerase chain reaction of mRNA that interleukin (IL)-18 is expressed by osteoblastic stromal cells. The stromal cell populations used for comparison differed in their ability to promote osteoclast-like multinucleated cell (OCL) formation. mRNA for IL-18 was found to be expressed in greater abundance in lines that were unable to support OCL formation than in supportive cells. Recombinant IL-18 was found to inhibit OCL formation in cocultures of osteoblasts and hemopoietic cells of spleen or bone marrow origin. IL-18 inhibited OCL formation in the presence of osteoclastogenic agents including 1\(\alpha\),25-dihydroxyvitamin D\(_3\), prostaglandin E\(_2\), parathyroid hormone, IL-1, and IL-11. The inhibitory effect of IL-18 was limited to the early phase of the cocultures, which coincides with proliferation of hemopoietic precursors. IL-18 has been reported to induce interferon-\(\gamma\) (IFN-\(\gamma\)) and granulocyte/macrophage colony-stimulating factor (GM–CSF) production in T cells, and both agents also inhibit OCL formation in vitro. Neutralizing antibodies to GM–CSF were able to rescue IL-18 inhibition of OCL formation, whereas neutralizing antibodies to IFN-\(\gamma\) did not. In cocultures with osteoblasts and spleen cells from IFN-\(\gamma\) receptor type II–deficient mice, IL-18 was found to inhibit OCL formation, indicating that IL-18 acted independently of IFN-\(\gamma\) production: IFN-\(\gamma\) had no effect in these cocultures. Additionally, in cocultures in which spleen cells were derived from receptor-deficient mice and osteoblasts were from wild-type mice and vice versa, we identified that the target cells for IFN-\(\gamma\) inhibition of OCL formation were the hemopoietic cells. The work provides evidence that IL-18 is expressed by osteoblasts and inhibits OCL formation via GM–CSF production and not via IFN-\(\gamma\) production.

In the process of osteoclast formation, there is an absolute requirement for cell to cell contact between osteoclastic precursor cells of hemopoietic origin and bone marrow stromal or osteoblastic cells to commit the hemopoietic cell towards osteoclast development (1–3). The osteoclast is a large multinucleated giant cell that contains between 2 and 100 nuclei per cell, expresses tartrate-resistant acid phosphatase (TRAP\(^1\)) activity and calcitonin receptors, has the ability to form resorption pits on bone or dentine slices and differs from macrophage polykaryons (4). We developed a

\(^{1}\)Abbreviations used in this paper: 1\(\alpha\),25(OH)\(_2\)D\(_3\), 1\(\alpha\),25-dihydroxyvitamin D\(_3\); eGM–CSF, neutralizing antibody to GM–CSF; eIFN-\(\gamma\), neutralizing antibody to IFN-\(\gamma\); ddPCR, differential display PCR; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; GM–CSF, granulocyte/macrophage colony-stimulating factor; IFN-\(\gamma\)R\(_\beta\)/2, IFN-\(\gamma\) receptor type II knockout; IGIF, interferon-\(\gamma\)-inducing factor; OCL, osteoclast-like multinucleated cells; PGE\(_2\), prostaglandin E\(_2\); PTH, parathyroid hormone; R T, reverse transcription (or transcribed); TRAP, tartrate resistant acid phosphatase.
cocculture system of mouse hematopoietic and primary osteoblastic stromal cells with which to investigate osteoclast development in vitro. In this cocculture system, osteoclast-like cells (OCLs) are produced in response to a number of systemic or local factors, including 1α,25-dihydroxyvitamin D₃ (1α,25(OH)₂ D₃), prostaglandin E₂ (PGE₂), parathyroid hormone (PTH), or the interleukins (IL-1, IL-6, and IL-11) (1, 5–7). Generation of these OCLs requires that the osteoblastic and hemopoietic cells are cultured on the same surface (8). These cells are multinucleated and express the OCL characteristics of TRAP activity and calcitonin receptors, and have the capacity to resorb bone (8). In short, they display the properties of mature bonafide osteoclasts. However, the production of such OCLs in cultures can be inhibited by a number of interleukins (e.g., IL-4, IL-10, and IL-13) and IFN-γ and GM-CSF (9–17).

We previously reported that bone marrow-derived stromal cell lines, MC3T3-G2/PA6 and ST2, had the capacity to support OCL formation in cocultures with hemopoietic cells (18). Recently, we established several bone marrow-derived stromal cell lines from a transgenic mouse and immortalized with a temperature-sensitive variant of the immortalizing gene of SV40 (tsA58; 19, 20). To identify osteoblastic stromal cell lines with which to investigate osteoclast formation, and we investigated its mode of action.

Materials and Methods

Animals, Cell Lines, and Drugs. Newborn (0-1-d-old) C57BL/6j mice and 6-9-wk-old male C57BL/6j mice were purchased from Monash University Animal Services Centre (Clayton, Australia). We thank Professor M. Auget (Swiss Institute for Experimental Cancer Research, Switzerland) and Dr. P. Tipping (Monash Medical Centre, Australia) for access to the IFN-γ-type II receptor knockout mice (IFN-γ− R−/−) (24). The murine stromal cell lines, tsJ2, tsJ10, and tsJ14, were generated by transfection with a retroviral vector expressing a temperature-sensitive variant of the immortalizing gene of SV40 (tsA58; 19, 20). 1α,25(OH)₂ D₃ (PGE₂) was purchased from Sigma Chem. Co. (St. Louis, MO). Recombinant mouse IL-18 and rabbit polyclonal antibodies to mouse IL-18 were obtained from Genzyme (Cambridge, MA). Recombinant mouse IL-12 was purchased from Biogenex (San Ramon, CA). Recombinant mouse IL-18 and rabbit polyclonal antibodies to mouse IL-18 were obtained from Dr. J.A. Hamilton (Department of Medicine, Royal Melbourne Hospital, Australia). The murine stromal cell lines, tsJ2, tsJ10, and tsJ14, were generated by transfection with a retroviral vector expressing a temperature-sensitive variant of the immortalizing gene of SV40 (tsA58; 19, 20). 1α,25(OH)₂ D₃ was purchased from Wako Pure Chemical Co. (Osaka, Japan). Bone marrow and spleen cells were obtained from adult and from newborn mice, respectively (6). Osteoblastic cells were cocultured with bone marrow or spleen cells as described (6, 25, 26). In short, primary osteoblastic cells (2×10⁵ per well) and nucleated spleen cells (1×10⁶ per well) or marrow cells (5×10⁶ per well) were cocultured in 48-well plates (Corning Glass Inc., Corning, NY) with 0.4 ml of α-MEM ( Gibco BRL, Gaithersburg, MD) containing 10% fetal bovine serum (CytoSystems, Castle Hill, NSW, Australia) in the presence of test chemicals. Cultures were incubated in quadruplicate and cells were replenished on day 3 with fresh medium. OCL formation was evaluated after culturing for 6 to 7 d. Adherent cells were fixed and stained for TRAP, and the number of TRAP-positive OCLs was scored as described (6). For TRAP staining, adherent cells were fixed with 4% formaldehyde in PBS for 3 min. After treatment with ethanol/acetone (50:50 vol/vol) for 1 min, the well surface was air-dried and incubated for 10 min at room temperature in an acetate buffer (0.1 M sodium acetate, pH 5.0) containing 0.01% naphthol AS-MX phosphate (Sigma) as a substrate and 0.03% red violet LB salt (Sigma) as a stain for the reaction product in the presence of 50 mM sodium tartrate. TRAP-positive cells appeared dark red. The expression of calcitonin receptors was also assessed by autoradiography using [¹²⁵I]salmon calcitonin as described (25).

Differential Display PCR. Total cellular RNA was extracted from cell lines or mouse tissues using guanidine thiocyanate-phenol-chloroform and used for reverse transcriptase PCR (RT-PCR) essentially as described (27, 28). Differential display PCR (ddPCR) was performed essentially as described (21, 28), except 1 μg of total RNA was reverse transcribed. PCR products were cloned into a PCR Script II (Stratagene, La Jolla, CA) or pGEM-T (Promega, Madison, WI) DNA sequence analysis was performed using a T7 sequencing kit (Pharmacia Biotech, Uppsala, Sweden). Oligonucleotides were synthesized on an oligo 1,000M DNA Synthesizer (Beckman Instruments, Inc., Fullerton, CA). The oligonucleotides were the following: ddPCR, DDMR-2 (5′-CTTGGATTGCC-3′) and T2/VA (5′-TTTTTTTTTTTTTTTTCGGGATCAAGG-3′); nucleotides 286-308 Fig. 1B) and IL-18-2 (antisense strand oligonucleotide 5′-GGGATTTCTTGGTTATGAGAAGAAGACCG-3′; nucleotides 804-828 Fig. 1B), and IL-18-3 (sense strand oligonucleotide 5′-TTCTTGGCCTAAGAAGACCCGTG-3′, nucleotides 641-660 Fig. 1B) served as internal oligonucleotide probe for hybridization studies as described (27, 28); mouse glyceraldehyde-3-phosphate dehydrogenase (GAPDH) primers were GAPDH-1, GAPDH-2 (5′-ATGAGGTCCACCCACCTGTG-3′, nucleotides 640-659; 29), and GAPDH-4 as described (30).

Results

Identification of IL-18 mRNA. To identify stromal cell genes potentially involved in osteoclastogenesis, we have used differential display of eukaryotic mRNA (ddPCR) (21) to identify genes differentially expressed between osteoclastogenic supportive and nonsupportive stromal cell lines. The stromal cell lines were established after immortalization with large T antigen (19, 20) and were stable in their phenotype. The cell lines tgs2 and tgs10 could support OCL formation after hydrocortisone (10⁻⁶ M) or PGE₂ (10⁻⁵ M) and 1α,25(OH)₂ D₃ (10⁻⁸ M) treatment. However, in the absence of hydrocortisone or PGE₂ and 1α,25(OH)₂ D₃, the tgs2 and tgs10 cell lines were unable to support OCL forma-
tion. In contrast, the tsJ14 cell line was unable to support osteoclast formation even in the presence of hydrocortisone or PGE2 and 1α,25(OH)2 D3.

RNA was extracted from OCL-inductive lines (tsJ10 treated with hydrocortisone and tsJ2 treated with PGE2 and 1α,25(OH)2 D3) and from the OCL-noninductive cells (tsJ14 treated with hydrocortisone or with PGE2 and 1α,25(OH)2 D3) and subjected to ddPCR analysis. Using an array of anchored 3′ primers (T12VA, T12VC, T12VG, or T12VT; where V = A, C, G) and defined 10-mer primers (which act as 5′ primers), several mRNA species were found to be upregulated in OCL-inductive cells (tsJ10 cells treated with hydrocortisone and tsJ2 cells treated with PGE2 and 1α,25(OH)2 D3; Fig. 1A, lanes 1 and 3; arrowed at right) with respect to the OCL-noninductive cells (tsJ14 cells treated with hydrocortisone and PGE2 and 1α,25(OH)2 D3; Fig. 1A, lanes 1 and 3; arrowed at left) compared with respect to the OCL-nonsupportive cells (tsJ14 treated with hydrocortisone; Fig. 1A, lane 2) compared with OCL-supportive cells (tsJ10 cells treated with hydrocortisone; Fig. 1A, lane 1). This band of 19S bp was extracted, cloned, and sequenced and was identified as mouse IFN-γ-inducing factor (IL-18) (22, 23). The RT-PCR–generated fragment was derived from the 3′ end of the mRNA, indicating that the anchored PCR primer had primed near the poly(A) tail (Fig. 1B). Additionally, the degenerate 10-mer 5′ primer DDM-R-2 only differed by one nucleotide from that of the IL-18 cDNA sequence (Fig. 1B, at nucleotide 640, A versus C, respectively). The band designated by IL-18 in Fig. 1A appeared to be enhanced by PGE2 and 1α,25(OH)2 D3 as indicated by the amount of amplified product resulting from PCR of RNA from cells treated with these agents (Fig. 1A, lanes 3 and 4); however, this was complicated by coamplification of another mRNA species under these treatment conditions. Thus, the designated band corresponding to amplified IL-18 cDNA in Fig. 1A was composed of at least two distinct mRNA species.

To confirm differential expression of IL-18 mRNA in cell lines that were OCL-inductive rather than noninductive, semiquantitative RT-PCR using IL-18–specific oligonucleotides (IL-18-1 and IL-18-2) was undertaken and the PCR product was confirmed by an internal specific oligonucleotide for IL-18 (IL-18-3) (Fig. 1C). IL-18 mRNA levels were found to be higher in the OCL-inductive cells (Fig. 1C, lanes 2 and 4) than the inductive cells (Fig. 1C, lane 1).

Figure 1. Identification of IL-18. (A) An example of a ddPCR gel. Lanes correspond to RNA from different sources: (lane 1) hydrocortisone-treated tsJ10 cells, (lane 2) hydrocortisone-treated tsJ14 cells, (lane 3) 1α,25(OH)2 D3- and PGE2-treated tsJ2 cells, and (lane 4) 1α,25(OH)2 D3- and PGE2-treated tsJ14 cells. The PCR fragment identified as IL-18 is indicated by the arrow on the left. Indicated by the arrow on the right is a PCR fragment corresponding to a hitherto uncharacterized mRNA species, which is expressed in greater abundance in the OCL-supportive cell lines. The osteoclast-supporting activity (OSA) of these cell lines is indicated below the gel: plus (supportive) or minus (nonsupportive). (B) Nucleotide sequence of mouse IL-18 (GenBank™ accession number D49940). The region corresponding to the differential expressed PCR fragment isolated from (A) is between nucleotides 636–830. Sequences underlined correspond to oligonucleotides specific to IL-18 used for reverse transcription and detection of RT-PCR products (IL-18-1, IL-18-3, and IL-18-2 from 5′ to 3′). Nucleotides in capitals correspond to the coding region of IL-18, whereas those in lower case correspond to the 5′ and 3′ untranslated sequences. (C) Semiquantitative RT-PCR analysis of IL-18 mRNA. PCR products for RNA isolated from different sources were reverse transcribed with oligo(dT) and PCR performed with the primers IL-18-1 and IL-18-2 for 23 cycles, which was in the log-linear range of amplification. Lanes correspond to RNA from (1) hydrocortisone-treated tsJ10 cells, (2) hydrocortisone-treated tsJ14 cells, (3) 1α,25(OH)2 D3- and PGE2-treated tsJ2 cells, and (4) 1α,25(OH)2 D3- and PGE2-treated tsJ14 cells. Resultant PCR products were electrophoresed, transferred to a nylon membrane, and hybridized with α-32P–labeled internal detection oligonucleotide for IL-18. Results obtained are presented in the following gel image and are indicated as follows: plus (supportive) or minus (nonsupportive).
IL-18 was added to cocultures with the osteoclastogenic agents 1α,25(OH)2 D3, PGE2, PTH, or IL-11. IL-18 or IFN-γ inhibited OCL formation induced by each of these agents of osteoclastogenesis (Fig. 3).

IL-18 Inhibits the Early Stage of OCL Formation. Next, we addressed the action of IL-18 and IFN-γ on the process of OCL formation. Treatment of cocultures revealed that the inhibitory actions of IL-18 on OCL formation occurred during the first 3 d of coculture (proliferating period), whereas IL-18 had no effect during the last 3 d of coculture (Fig. 4). In contrast, although IFN-γ inhibited OCL formation over the entire coculture period (days 0–6), it inhibited OCL formation by 50% during both the proliferating period (days 0–3) and the differentiation phase (days 3–6) (Fig. 4). These results suggested a fundamental difference between the inhibitory effects of IL-18 and IFN-γ, although potential stimulation of IFN-γ production by IL-18 could not be excluded by these experiments alone.

IL-18 Acts by Inhibitory Mechanism Distinct from IFN-γ. Next, we sought to distinguish the inhibitory mechanisms of IL-18 and IFN-γ by using neutralizing antibodies to either IL-18 or IFN-γ in coculture experiments. We initially titrated the two antibodies (α-IL-18 antibody or α-IFN-γ antibody) and determined the concentration at which each

Figure 2. OCL formation in cocultures of mouse bone marrow and osteoblastic cells in the presence of IL-18 (A) or IFN-γ (B). Mouse bone marrow and primary osteoblastic cells were cocultured with 1α,25(OH)2 D3 (10−8 M) and PGE2 (10−7 M) in the presence of increasing concentrations of IL-18 (A) or IFN-γ (B). For negative and positive controls, cocultures were performed in the absence and presence of 1α,25(OH)2 D3 and PGE2, respectively. After culture for 7 d, TRAP-positive OCLs were counted. Data are expressed as the means ± SEM of quadruplicate cultures and are representative of three similar experiments.

Figure 3. Effect of IL-18 (10 ng/ml) on OCL formation in cocultures of mouse bone marrow and osteoblastic cells in the presence of 1α,25(OH)2 D3, PGE2, PTH, IL-11, and IL-1. OCL formation can be enhanced by a number of agents that act through different second messenger systems (e.g., vitamin D receptor, cAMP, and gp130) (1). To examine whether the inhibitory actions of IL-18 on OCL formation was stimulus specific or whether it acted as a general inhibitor, IL-18 was added to cocultures with the osteoclastogenic agents 1α,25(OH)2 D3, PGE2, PTH, or IL-11. IL-18 or IFN-γ inhibited OCL formation induced by each of these agents of osteoclastogenesis (Fig. 3).
antibody could rescue either IL-18–induced inhibition of OCL formation (for α-IL-18 antibody) or IFN-γ–induced inhibition of OCL formation (for α-IFN-γ antibody). A polyclonal neutralizing IL-18 antibody (at 30 μg/ml) rescued IL-18 inhibition of OCL formation (Fig. 5 A), however, this antibody (at 30 μg/ml) did not rescue the IFN-γ inhibition of OCL formation (Fig. 5 A). Because IFN-γ was speculated to be a downstream effector molecule of IL-18, we did not expect the neutralizing IL-18 antibody to rescue IFN-γ inhibition of OCL formation. The monoclonal IFN-γ neutralizing antibody at very low concentration (1 ng/ml) rescued IFN-γ inhibitory effects, whereas even at 2,000-fold excess of the IFN-γ rescuing concentration (20 μg/ml) it did not protect against IL-18 inhibition of OCL formation (Fig. 5 B). The inability of the IFN-γ-neutralizing antibody to rescue OCL formation after IL-18 treatment further suggested that IL-18 was not acting through IFN-γ. Finally, we made use of IFN-γ R−/− mice (24). Cocultures of osteoblastic cells and spleen cells derived from the IFN-γ R−/− mouse were treated with either IL-18 or IFN-γ. IFN-γ, as expected, was unable to elicit an inhibition of OCL formation in these cocultures due to the absence of its cognate receptor on any cells (Fig. 6). In contrast, IL-18 inhibited OCL formation in these cocultures in a dose-dependent manner with a maximal effect at 10 ng/ml (Fig. 6), which is similar to normal mice cocultures as described above (see Fig. 2 A). This served as definitive proof that IL-18, although capable of inducing IFN-γ (a known inhibitor of OCL formation), mediated its inhibitory action on OCLs via an IFN-γ-independent mechanism.

IL-18 Inhibits OCL Formation Via GM-CSF. In addition to enhancing IFN-γ production, IL-18 has been shown to induce GM-CSF production in mitogen-stimulated peripheral blood mononuclear cells (23). Like IFN-γ, GM-CSF is a potent inhibitor of osteoclast formation in the mouse system (16, 26, 32–34), suggesting that GM-CSF may also be a candidate molecule involved in the IL-18 in-
1010 Mechanism of IL-18 Inhibition of Osteoclast Formation

Figure 6. OCL formation in cocultures of spleen cells and osteoblastic cells derived from IFN-γ receptor type II knockout (IFN-γ R−/−) mice. IL-18 (10 ng/ml) or IFN-γ (50 U/ml) were present over the entire culture period. For negative and positive controls, cocultures were performed in the absence of presence of 1α,25(OH)2 D3 (10−8 M) and PGE2 (10−7 M), respectively. After culture for 7 d, TRAP-positive OCLs were counted. Data are expressed as the means ± SEM of quadruplicate cultures. This experiment was repeated twice.

Figure 7. OCL formation in cocultures of normal C57/BL6 mouse-derived spleen cells with osteoblastic cells derived from IFN-γ R−/− mice and cocultures of normal or IL-18 (10 ng/ml) or IFN-γ (50 U/ml) were present over the entire culture period. For negative and positive controls, cocultures were performed in the absence and presence of 1α,25(OH)2 D3 (10−8 M) and PGE2 (10−7 M), respectively. After culture for 7 d, TRAP-positive OCLs were counted. Data are expressed as the means ± SEM of quadruplicate cultures. This experiment was repeated twice.

Figure 8. Effect of neutralizing antibodies against GM-CSF to rescue OCL formation in cocultures of mouse bone marrow and osteoblastic cells treated with GM-CSF (0.1 ng/ml), IL-18 (10 ng/ml), or IFN-γ (50 U/ml). Cocultures were incubated in the presence or absence of GM-CSF, IL-18, or IFN-γ and the effect of neutralizing antibodies to GM-CSF (1 μg/ml) were determined. For negative and positive controls, cocultures were performed in the absence and presence of 1α,25(OH)2 D3 (10−8 M) and PGE2 (10−7 M), respectively. After culture for 7 d, TRAP-positive OCLs were counted. Data are expressed as the means ± SEM of quadruplicate cultures. Similar results were obtained with three repeat experiments.

Discussion

In this report, we establish that a recently discovered cytokine, IL-18, can inhibit OCL formation in mouse cocultures. Elevated expression of mRNA for IL-18 was observed in stromal cell lines that were unable to support OCL formation, and recombinant IL-18 was a potent inhibitor of OCL formation in vitro. The discovery of IL-18 resulted from its ability to induce IFN-γ production by T cells (22). Although IFN-γ is known to inhibit osteoclast formation in vitro (4), the present experiments exclude IFN-γ as an intermediate in the inhibitory effect of IL-18 on osteoclast formation, for a number of reasons.

First, antibodies against IFN-γ failed to rescue IL-18 inhibition of OCL formation in cocultures, although they were able to prevent the effect of IFN-γ itself. Second, in our experiments with cells from type II IFN-γ R−/− mice, IL-18 still manifested its inhibitory action on osteoclast formation. Furthermore, an effect of IL-18 had no effect on the production of macrophages in vitro (Udagawa, N., and J.A. Hamilton, unpublished data), nor did IL-18 influence bone resorption by freshly isolated osteoclasts (Holloway, W., and M.T. Gillespie, unpublished data). These latter two sets of observations contrast with the effects of IFN-γ, which promotes the proliferation of macrophages in vitro (35) and inhibits resorption by freshly isolated osteoclasts (36).
Finally, our finding that IFN-γ submaximally inhibited OCL formation during both the proliferative (days 0–3) and the maturation (days 3–6) phases of the coculture indicated that the inhibitory actions of IL-18 on OCL formation do not involve IFN-γ as an intermediate.

On the other hand, these results indicate that GM-CSF might be a molecular intermediate in the inhibitory effect of IL-18 on osteoclastogenesis. This arises from the fact that a neutralizing antibody against GM-CSF was able to prevent IL-18 inhibition of OCL formation. Furthermore, the finding that the effect of IL-18 in our experiments was on the early phase of the cocultures, in which proliferation of hematopoietic precursors is the dominant process, is entirely consistent with GM-CSF involvement. Conflicting reports exist for the action of GM-CSF on the production of osteoclasts in vitro. In human bone marrow cultures, GM-CSF stimulated the formation of multinucleated cells (37), whereas in mouse marrow cultures GM-CSF inhibited OCL formation (16, 26, 32–34). Our results in the cocultures are in accordance with the latter.

IL-18 shares substantial identity with IL-1, including the IL-1 signature-like sequence (F-X₁₁₂-F-X-S-X₆-F-L; 23) and secondary structure (38). These properties suggested that IL-18 may be functionally similar to the IL-1 family of cytokines. Thus, it was foreseeable that IL-18 may bind to the IL-1 receptor and could potentially inhibit OCL formation in a manner akin to the IL-1 receptor antagonist (39). Indeed, the suggestion was made that IGIF (22) should be called IL-1γ (39). However, attempts to displace IL-18 inhibition of OCL formation with excess of IL-1β were unsuccessful, indicating that either IL-18 binds to a receptor distinct from that for IL-1 or that it has a higher affinity for the IL-1 receptor than IL-1β. The identity of the IL-18 receptor remains to be established.

The finding that IL-18 mRNA was elevated in OCL-noninductive stromal cells, and that IL-18 could inhibit OCL formation, implies that IL-18, and by inference GM-CSF, participates in local control of osteoclastogenesis. Thus, the regulation of IL-18 and GM-CSF expression in the bone microenvironment by circulating hormones or by other local factors may function to limit the generation of osteoclasts.
