Abstract

Background

Checkpoint kinases 1/2 (Chk1/2) has an important role in somatic cells development and oocyte meiotic maturation. However, the role of Chk1/2 in folliculogenesis has not been fully elucidated. The aim of this study was to assess the effects of Chk1/2 inhibition on ovarian folliculogenesis and granulosa cells development in mice.

Methods

Preantral follicles (100 µm- 120 µm) and granulosa cells from pre-ovulatory follicles (pre-GCs) of mice were isolated and cultured with or without Chk1/2 inhibitor AZD7762. Preantral follicles were cultured for 96 h. Then, follicle morphology and follicular growth were assessed every 48 h. Granulosa cells were cultured for 48 h with or without AZD7762, after which cell apoptosis, cell proliferation, and cell cycle analysis were assessed; meanwhile, the mRNA expression of PCNA and Bax were measured by real-time RT-PCR, and PCNA and Bax protein were measured by Western blot.

Results

Compared with control follicles, AZD7762 inhibited growth of preantral follicles. Furthermore, inhibition of Chk1/2 significantly induced apoptosis and inhibited the proliferation of granulosa cells, arrested cell cycle at S and G2/M phases, and decreased G1 phase fraction. Also, the expression of PCNA mRNA and protein were significantly reduced, while Bax mRNA and protein were significantly increased post AZD7762 treatment in granulosa cells.

Conclusions

This study revealed that Chk1 and Chk2 have a crucial role during preantral follicular development by regulating the proliferation and apoptosis of granulosa cells.

Introduction

In mammals, oocytes arrested in the diplotene stage of the first meiotic prophase are surrounded by a single, squamous layer of somatic cells to form a finite population of non-growing primordial follicles [1]. Primary follicles are recruited from the primordial pool as oocytes grow. These cells continue to proliferate to form many layers surrounding the oocyte and eventually become granulosa cells [2]. This transition is associated with participation in the subsequent phases of follicular growth, as the measured recruitment of primordial follicles from the resting pool of follicles is crucial for the development of folliculogenesis throughout the reproductive lifespan of mammals [3]. However, apoptosis reduces this
endowment by two-thirds before birth. In addition, granulosa cells apoptosis is the main cause of follicular atresia at different stages of their growth [4, 5].

When atresia occurs, pyknotic nuclei are first observed in granulosa cells. Then a detachment of granulosa cell layer and fragmentation of basal membrane occurs, ultimately resulting in hypertrophied thecal cells and disruption of thecal integration and thecal vessels [6]. Granulosa cell apoptosis may occur much earlier than the morphological changes in follicular atresia, which can be observed only when granulosa cell apoptosis reaches a certain degree [7]. Generally, proliferation and differentiation of granulosa cells lead to follicular maturation and ovulation, whereas apoptosis and degeneration of granulosa cells result in follicular atresia [8]. Many apoptosis-related factors have been implicated in follicular atresia, including death ligands and receptors, intracellular pro- and anti-apoptotic molecules, cytokines, growth factors, and several apoptosis-related genes [9]. Although new regulatory factors are continuously being identified, comprehensive knowledge of the signaling networks that function during granulosa cell apoptosis remains limited.

Checkpoint kinases are threonine/serine that can be divided into two subtypes, Chk1 and Chk2, which have a critical role in DNA damage responses, cell cycle control, and cell survival [10]. In response to DNA damage, Chk1 and Chk2 are activated by PI3 kinase-related kinases ATM and ATR, respectively, aiming at many downstream substrates that coordinate cell cycle checkpoint activation, DNA restitution, and apoptosis [11]. Moreover, Chk1/2 has also been implicated in anaphase entry, chromosome condensation, and maintenance of genome integrity in somatic cells in the absence of DNA damage [12]. Chk1 knockout mice are embryonically lethal, suggesting that Chk1 is an important molecule during early embryonic development [13]. Moreover, embryonic stem cells specific Chk1 knockout mice display premature activation of Cdc2/cyclin B and mitotic catastrophe [14]. At the same time, Chk2-deficient cells show significant defects in UV-induced apoptosis and G1/S arrest [15]. Preliminary unpublished observations from our laboratory showed that the expression of Chk1/2 fluctuates during follicular development, suggesting the importance of Chk1/2 in folliculogenesis; yet, the exact role in follicular development is not fully understood.

In the present study, Chk1/2 inhibitor (AZD7762) was used to further investigate the role of Chk1/2 during preantral follicular development and cellular proliferation and apoptosis.

**Materials And Methods**

**Animals**

Female Kunming white mice of 12-14 (9 g-10 g) or 21-23 (12 g-14 g) days old were obtained from the Centre of Laboratory Animals of Hubei Province (Wuhan, PR China). Mice were housed in an environment with a temperature of 24 ± 1 ºC, relative humidity of 50 ± 1%, and a light/dark cycle of 12/12 hr, and given food and water *ad libitum*. All animal studies (including the mice euthanasia procedure) were done in compliance with the regulations and guidelines of the Hubei Research Center of Experimental Animals.
and conducted according to the AAALAC and the IACUC guidelines (Approval ID: SCXK (Hubei) 2008-0005).

Isolation and culture of preantral follicles and granulosa cells

Preantral follicles (100 µm-120 µm) obtained from the ovaries of 12-14 days old female mice were gently separated using the 1 ml syringe needle under a stereomicroscope (CKX41SF; Olympus Optical Technology Philippines Inc., Lapu-Lapu City, Philippines), and observed under an inverted microscope (TE2000-U; Nikon). Follicles with two or three layers of granulosa cells and a diameter between 100 and 120 µm were collected and cultured in α-Minimum Essential Media (α-MEM, Gibco) containing 10 µg/mL of ITS (0.55 mg/mL human transferrin, 1.0 mg/mL recombinant human insulin, and 0.5 µg/mL sodium selenite) and 100 mIU/mL of follicle-stimulating hormone (FSH, Sigma Chemical Company, St. Louis, MO) with one follicle per well in 96-well culture plates in a humidified atmosphere containing 5%CO₂/95% air at 37ºC for 48 h. After that, follicles were cultured in α-MEM medium containing ITS with or without 1 µM of AZD7762 (Axon Medchem BV, Cat. No. Axon 1399) for an additional 96 h and observed under microscopy (TE2000-U; Nikon) for assessment of morphology and follicular growth, as indicated by follicular diameter (F.D). The concentration of the Chk1/2 inhibitor used in our study was selected based on previous study results [16].

GCs from pre-ovulatory follicles (pre-GCs) were taken from ovaries of 21-23 days old mice injected with 10 IU pregnant-mare serum gonadotropin (PMSG, SanSheng, Ningbo) for 44–48 h and cultured as previously described [17]. Briefly, granulosa cells were cultured in Dulbecco’s Modified Eagle’s Medium/Nutrient F-12 (DMEM/F12; Gibco) medium with 10% fetal bovine serum (FBS; Invitrogen), 100 U/mL penicillin, and 100 µg/mL streptomycin (Gibco). All cultures were maintained in DMEM/F12 medium in a humidified atmosphere containing 5%CO₂/95% air at 37ºC.

Cell proliferation assay

Cell proliferation assay was measured using a WST-1 Cell Proliferation Assay kit (Beyotime, Wuhan, China). Briefly, granulosa cells were cultured in a 96-well culture plate (4x10³ cells/well) for 24 h. Cells were then exposed to a gradually increased concentration of AZD7762 (1, 5, 10, 20, and 50 µM) for 24 h, 48 h, and 72 h. After each time point, 10 µl of freshly prepared WST-1 solution was added to each well, along with the culture medium. The absorbance of the samples was measured after 1 h at 37ºC using a microplate reader (Bio-Rad Laboratories, Inc., Hercules, CA, USA) at 450 nm.

Cell cycle assay
For cell cycle analysis, pre-GCs were cultured in a 6-well culture plate with 0 μM or 1 μM AZD7762 for 48 h. After being washed with PBS, the cells were digested and harvested using the Cell Cycle Detection kit (KeyGen Biotech Co., Ltd., Nanjing, China). Cells were then fixed in 70% ethanol at 4°C overnight, washed with PBS, and incubated with 100 μL RNase A at 37°C for 30 min. Then, the cells were stained with 400 μL PI in the dark for 30 min at 4°C and analyzed through flow cytometry using a BD FACS Calibur [excitation wavelength (Ex), 488 nm; emission wavelength (Em), 530 nm; Becton-Dickinson, Mountain View, CA, USA].

**Cell apoptosis assay**

Pre-GCs were cultured in 6-well culture plate by adding 0 μM or 1 μM AZD7762 for 48 h. After being washed in PBS, cells were digested and harvested. Annexin V–FITC/PI kit (AntGene, Wuhan) was used to detect the proportion of apoptotic cells according to manufacturer’s instructions. Cells were incubated in AnnexinV–FITC and PI solution at room temperature in the dark for 15 min, after which a 300 μL of 1×binding buffer was added to each sample. Flow cytometric analysis was planned through a BD FACS Calibur (Becton, Dickinson and Company, USA; Ex, 488 nm and Em, 530 nm). Cells that stained positive for annexin V-FITC were calculated as apoptotic cells.

**RT-PCR analysis**

RT-PCR analysis was performed to confirm that inhibition of Chk1/2 by AZD7762 could regulate genes expression, *PCNA*, and *Bax*. Pre-GCs were cultured with 0 μM or 1 μM AZD7762 for 48 h, after which a total RNA was extracted using the RNAprep pure Cell/Bacteria Kit (TIANGEN, Beijing), and *in vitro* transcription was performed through RevertAid™ First-strand cDNA Synthesis kit (Thermo, Wuhan). RT-PCR was quantified using special primer pairs (Table 1) and QuantiFast® SYBR® Green RT-PCR kit (QiaGen, Wuhan) on the Roche LightCycler® 480 according to manufacturer’s instructions. The gene expression results were normalized to the basal level of β-actin. The $2^{-\Delta\Delta\text{Ct}}$ was used to calculate the relative fold change of each gene.

| Genes | Primer sequences |
|-------|-----------------|
| *PCNA* Forward | AGACAGTGGAGTGGCTTTT |
| Reverse | CCGAGACCTTAGCCACATT |
| *Bax* Forward | CCAGGATCGTGCCACCAA |
| Reverse | CAAAGTAGAAGGGCAACCAC |
| β-actin Forward | CCCATCTACGAGGCTAT |
| Reverse | TGTCACGCACGATTCC |
Western blot

After AZD7762 treatment for 48 h, cells were harvested in RIPA buffer (Santa Cruz), which contained 10 mg/mL protease inhibitors cocktail (Santa Cruz) and 10 mM phenylmethylsulfonyl fluoride (PMSF; Ding-Guo, Beijing). The concentration of total protein was determined by bicinchoninic acid (BCA) assay (Pierce, Rockford, USA), and 20 mg of total protein was subjected to gel electrophoresis as previously described [17]. Monoclonal mouse anti-β-actin IgG (1:1000 dilution; Santa Cruz), monoclonal mouse anti-PCNA IgG (1:600 dilution; Santa Cruz), and monoclonal rabbit anti-Bax IgG (1:1000 dilution; EPI) were used as the primary antibody, and HRP-conjugated anti-mouse or rabbit secondary antibodies (1:2000 dilution; Boster, Wuhan) were used. The images were measured with a Gel-Pro analyzer 4.0 (Media Cybernetics, Silver Spring, MD, USA). The scanning intensities of the Western blots were analyzed using ImageJ software to quantify the target bands compared to the corresponding β-actin bands.

Statistical analysis

Experiments were independently performed at least three times, and data are presented as mean±SD. Differences between each group were analyzed by one-way ANOVA followed by Tukey’s Honesty Significant Difference (HSD) test using SPSS (Version 17.0; SPSS, Chicago, IL, USA); P< 0.05 was regarded as a statistically significant difference.

Results

Chk1/2 are essential for preantral follicular development

In order to assess the role of Chk1/2 during follicular development, we cultured preantral follicles with Chk1/2 broad-spectrum inhibitor (AZD7762) in vitro. In the control group, the gradual growth of follicles was observed, while follicles cultured with AZD7762 showed no growth or cell number reduction (Figure 1A and 1B, P<0.05). Meanwhile, as shown in Figure 1C, the granulosa cells of follicles treated with AZD7762 around the outer layer showed cell shrinkage and weak connection between cells compared with the control follicles. Thus, we predicted that the arrested development of preantral follicles and abnormalities of the morphology of follicles might be related to the granulosa cells status, including proliferation and apoptosis.

Inhibition of Chk1/2 induces granulosa cells apoptosis

As shown in Figure 2A, granulosa cells cultured with AZD7762 showed abnormal cell morphology. As seen in Figure 2B, the apoptosis rate in the AZD7762 group was significantly higher than in the control
In this study, AZD7762 was used to inhibit the function of both Chk1 and Chk2. Preantral follicles treated with AZD7762 showed a developmental abnormality. Moreover, granulosa cells treated with AZD7762 showed decreased cell growth, increased apoptosis, and abnormal cell cycle distributions. These results suggest that Chk1/2 has an important role in preantral follicular development and the growth of granulosa cells.

The development of preantral follicles includes oocyte growth, granulosa cell proliferation, differentiation, and apoptosis. However, more than 99% of follicles disappear, primarily due to the apoptosis of granulosa cells, and the majority of follicles become atretic during the early antral stage of development [18]. Thus, we selected the preantral follicles in this experiment, which were then treated with a Chk1/2 inhibitor to monitor the follicular development. Activated Chk1 and Chk2 have a full spectrum of substrates that are key cell cycle regulators. In the control group, the gradual growth of follicles was
observed, while follicles cultured with AZD7762 showed no growth or even negative growth (Fig. 1). These results suggested that Chk1/2 is essential for follicular development.

Gonadotropin can promote the differentiation of the granulosa cells, making them vulnerable to apoptosis. Thus, pre-GCs were selected to study the role of Chk1/2 in regulating the development of granulosa cells. The cells treated with AZD7762 showed decreased cell growth and increased cell apoptosis (Fig. 2 and Fig. 3). Similarly, a previous study has suggested that Chk1 is required for mitotic progression and proliferation of Hela cells through negative regulation of polo-like kinase 1 Plk1 [19]. Meanwhile, Chk1-depleted lobuloalveolar mammary epithelial cells do not proliferate and undergo apoptosis, suggesting that cell proliferation is important for apoptosis [20]. Likewise, in our study, a proliferation of granulosa cells was significantly inhibited and showed an uncoordinated cell cycle (Fig. 4). The link between apoptosis and proliferation suggests that death resulting from Chk1 depletion may involve mitotic alteration [21]. However, in some circumstances, Chk2 appeared to be at least in part able to make up for the loss of Chk1 in some cells [22]. Our preliminary studies of Chk1/2 inhibition in mouse oocytes supported this hypothesis [23]. Moreover, the cell cycle of pre-GCs was disturbed by inhibition of Chk1/2 and showed increased G2 and S stages (Fig. 4). As Chk1/2 are the key cell cycle checkpoint kinase, and the major function of Chk1 is to coordinate the cell cycle checkpoint response, including G1, S, G2/M, and M phase [24], Chk2 is needed for the optimal G2/M delay of G2 phase cells; Chk2-deficient cells show G1/S arrest [25]. Our study showed that Chk1/2 might affect ovarian function by regulating the state (proliferation or apoptosis) of GCs and the fate (growth or atresia) of follicular development.

Future studies should investigate the exact function of Chk1 and Chk2 in follicular development and the regulatory mechanism of the Chk1/2 network responsible for follicular development. Studies have shown that Chk1 is a potential target for treating cancer [24], so another important issue is evaluating the possibility of Chk1/2 in reducing follicular atresia. Therefore, we propose that Chk1/2 could represent an option for suppressing follicular atresia.

Conclusions

Our present results provide insight into the roles of Chk1/2 in mouse ovaries, including follicular development, granulosa cells proliferation, and apoptosis. These results suggest that Chk1/2 may have an important role in follicular development and ovarian functions. Furthermore, future research on the security application of AZD7762 as drugs in clinical therapy of cancer (especially female patients) is warranted.

Declarations

Funding

This study was supported by the Natural Science Foundation of Zhejiang (Program NO. LQ18H040008).
Competing Interests

There is no conflict of interest for all authors.

Authors’ contributions

XML and FC conceived and designed the experiments. XML, FC, and FZ performed the experiments. XML and JZZ analyzed the data and wrote the manuscript. All authors reviewed the manuscript.

Ethics approval

All animal studies (including the mice euthanasia procedure) were done in compliance with the regulations and guidelines of the Hubei Research Center of Experimental Animals and conducted according to the AAALAC and the IACUC guidelines (Approval ID: SCXK (Hubei) 2008-0005).
