INTRODUCTION

Homeostasis of potassium, the most abundant cation of plants, is maintained by the activity of transporters and channels of the plasma membrane and the tonoplast (Dreyer and Uozumi, 2010; Voelker et al., 2010). KCO3-like proteins have only been detected by FRET and BiFC (Voelker et al., 2006) but it is not known whether the polypeptide forms tetramers, a prerequisite for activity in the case of this one-pore subunit. Here we have applied a number of experimental approaches in order to get insights on the assembly state and possible function of AtKCO3.

MATERIALS AND METHODS

PLANT GENOTYPING AND ANALYSIS

The A. thaliana knock-out mutant kco3-1 (Salk_096038) was ordered from the Salk Institute. Genomic DNA was extracted from frozen leaves with 1 ml of CTAB extraction buffer (0.8% CTAB, 0.14 M sorbitol, 0.22 mM Tris–HCl, pH 6, 0.022 mM EDTA, 0.8 M NaCl, 1% N-Lauroylsarcosine). Confirmation of the T-DNA insertion in kco3-1 was done using the following primers: 5'CAGGAAGCCCCCTTCTAATTTCAATCAGTGCAGG (KCO3-fw1), 5'TTTTTTCAATGGATATCCCCAGG (KCO3-rv).
For phenotypic analysis, seeds were plated on MS media supplemented with 3% sucrose in axenic condition. One-week-old seedlings were transferred to media containing the appropriate solute for the growth test in different abiotic stress conditions and were vertically grown in 16 h day/8 h night conditions. Different potassium concentration: seedlings were transferred on K⁺ deficient medium (2.5 mM NaNO₃, 2.5 mM Ca(NO₃)₂, 2 mM NH₄NO₃, 2 mM MgSO₄, 0.1 mM FeNaEDTA, 25 μM CaCl₂, 25 μM H₂BO₃, 2 μM ZnSO₄, 2 μM MnSO₄, 0.5 μM CuSO₄, 0.2 μM Na₂MoO₄, 0.01 μM CoCl₂, 1% sucrose, pH 5.7), supplemented with low (100 μM) or high (2.5 mM) K⁺; salt stress: 75 mM NaCl; osmotic stress: 150 mM mannitol. Oxidative stress: 100 mM H₂O₂. Plants were grown on a shaker for 5 days, with daily change of media.

**GENERATION OF TRANSGENIC PLANTS**

Plasmid DNA required for sequencing purposes was prepared using Qiagen columns (Qiagen, Hilden, Germany). Sequence determinations were performed by MWG-Biotech (Ebersberg, Germany). Sequence determination was done for three clones of amplification errors. Primer sets specific for T-DNA amplification. Amplification was done on pBIBhygro-dnKCO3 with pKCO3-fwd (5′ATTAGTCGACACATGACAAATTGAATGAGATGACAAATG3′) and KCO3-rev primers (Figure 1B). Amplification product was double digested with Sall–SacI and cloned in Sall–SacI digested pBluescript. Positive clones were further confirmed by sequencing and transformed in *Agrobacterium tumefaciens* strain GV3101. The positive *Agrobacterium* clones were detected through PCR with gene-specific primers on mini preparation of DNA from *Agrobacterium*. Overnight-grown culture of *Agrobacterium* was infiltrated in Col-0 wild-type plants through floral dip method. Seeds from infiltrated plants were screened on hygromycin-containing medium to select transgenic plants. Seedlings surviving on hygromycin-containing medium were used for genotyping to detect the presence of transformed transgene.

To generate kco3-1 × drKCO3 transgenic plants, homozygous lines of drKCO3 were crossed with kco3-1 null-allele (Salk_96038) mutant. The seeds obtained from the crossed plants were then screened to procure dominant-negative knockout mutant plants of KCO3. These kco3-1 × drKCO3 were again in the next generation under self-fertilization condition. Seeds thus inherited after self-cross were screened by performing PCR reactions to obtain homozygous kco3-1 × drKCO3. AtKCO3 cDNA clones were isolated from cDNA preparations of *A. italiana* seedlings (C24 ecotype) using primers 5′CACCTGCCATCTTCAATCATG3′ (KCO3.seq) and 5′CCACCTGCCATCTTCAATCATG3′ (KCO3.rev). Fragments corresponding to the AtKCO3 cDNA were subcloned into pCRII (Stratagene, Heidelberg, Germany) giving rise to the plasmid pCRII-KCO3. Sequence determination was done for three clones of AtKCO3. To confirm the correct insertions, the cDNA clones were further confirmed by sequencing and transformed in *Agrobacterium*. The positive *Agrobacterium* clones were digested but some undigested product can be seen. The PCR product from kco3-1 mutant was digested but some undigested product can also be seen. The PCR product from kco3-1 × drKCO3 shows complete digestion.

**FIGURE 1** Genotyping of kco3-1 null-alleles, drKCO3 and kco3-1 × drKCO3 mutant plants. (A) Schematic representation of the Salk_083208 T-DNA insertion line that contains two head to head T-DNAs insertion at position 420 in the first exon of the KCO3 gene. (B) Schematic representation of drKCO3 mutant, where, in the first exon of the KCO3 gene, a dominant negative mutation has been created by mutating the GFGD motif to GRGD. Additionally, a recognition site of the restriction enzyme SacI has been inserted. (C) PCR was performed on genomic DNA with the indicated primer sets specific for T-DNA amplification. Amplification was obtained in case of kco3-1 and cace3-1 × drKCO3 while the wild-type and

![Image](https://example.com/image.png)
as described above. Plasmid pSSS-KCO3 was generated by inserting the AtKCO3 cDNA (Kpdh/blunt/EcoRI/cpRI-AtKCO3) into Small site of pBluescript (Högen and Wellmer, 1988). A C-terminal GFP-fusion construct was created using pH-355-T1H1-GFP-JFH1 (Hong et al., 1999). The AtKCO3 cDNA was amplified using the primers 5′-GCGCTCCGAATTCACATGACATGCCG-3′ (KCO3-FS1.forward) and 5′-ATACGCTCGACGAATGGTTCGGGTTGATAACATCCAG3′ (KCO3-FS1.reverse) and fused to GFP coding sequence via SaI/NotI site to generate pSSS-KCO3-GFP.

Transgenic Arabidopsis plants expressing KCO3 or KCO3-GFP were generated by vacuum infiltration with Agrobacterium tumefaciens strain GV3101 transformed with the constructs pSSS-KCO3 or 35S-KCO3-GFP. Kanamycin-resistant plants (T0) were identified. Experiments were conducted using T1 or T4 plants.

ANTIBODIES
The following antibodies were used in this study: rabbit polyclonal anti-GFP (1:1,000 dilution, Invitrogen), rabbit polyclonal anti-endoplasmic reticulum (1:1,000 dilution; Klein et al., 2006), rabbit polyclonal anti-PiP2 (1:10,000 dilution; Santoni et al., 2003), or chicken polyclonal anti-NTPDase raised against a synthetic peptide (NH2-SEKRNLLFGSLPRC-COOH) located at the N-terminus of AtKCO3 and provided by Covalab (Villeurbanne, France). The total IgG fraction from immunized rabbit was then purified using protein A bead column. The affinity-purified antibody was used at 1:2,000 through a resin-column containing the antigenic peptide. This antibody was able to detect the AtKCO3 protein in western blot analyses of the whole Arabidopsis cell extract.

VACUOLE ISOLATION, PATCH-CLAMP RECORDINGS, AND DATA ANALYSIS
Mesophyll tissue of Arabidopsis plants was enzymatically digested for 30 min at 30°C. The enzyme solution contained 0.3% (w/v) cellulase R-10, 0.03% (w/v) pectolyase Y-23, 1 mM CaCl2, 500 mM sorbitol, 10 mM MES, pH 5.3. Protoplasts were washed twice and maintained in W5 solutions by means of a gravity-driven perfusion system coupled to a peristaltic pump. Steady-state currents were monitored electronically throughout the experiment. No leak current subtraction procedure was applied. Patch pipettes had resistance values of 3.5–4 MΩ, when filled with pipette solution (vascular side) containing 200 mM KCl, 2 mM CaCl2, 2 mM MgCl2, 10 mM MES-KOH, pH 5.5. All bath solutions contained 100 mM KCl, 1 mM diethytritol (DTT), 3 mM Tris and additionally 1 mM EGTA for low-calcium conditions or 100 μM CaCl2 for high-calcium conditions (Yoo et al., 2007). The osmolarity of the pipette and bath solutions was adjusted to 500 and 540 mOsm, respectively, by the addition of D-sorbitol. Liquid junction potentials in our experimental conditions were smaller than 1 mV.

Immediately after the establishment of the whole-vacuole configuration, current recordings reproducibly displayed background currents with negative reversal potentials (Figure A1A). These currents gradually decreased at all membrane potentials and finally stabilized at a slightly positive reversal potential after 15–30 min in the whole-vacuole configuration (Figure A1B), depending on the vacuole size. Only vacuoles which reached this point were considered for data analysis and successively exposed to other bath solutions by means of a gravity-driven perfusion system coupled to a peristaltic pump. Steady-state currents with negative reversal potentials were normalized to the vascular membrane capacitance, which was on average 30 ± 3 pF (n = 22). Data are represented as mean values ± SEM (for the number n of vacuoles).

TOTAL PROTEIN ANALYSIS
Arabidopsis wild-type or transgenic plants were grown in sterile conditions on half-concentrated MS media (Duchefa Biochemie) supplemented with 10 g/l sucrose and 0.8% (w/v) phyto agar (Duchefa Biochemie) at 23°C under a 16/8 h light/dark cycle. 3–6 weeks old leaves were homogenized in ice-cold homogenization buffer (200 mM NaCl, 1 mM EDTA, 0.2% Triton X-100, 2% 2-mercaptoethanol, 100 mM Tris–Cl pH 7.8, supplemented with Complete protease inhibitor cocktail (Roche)). After centrifugation at 5,000 × g for 10 min at 4°C, the resulting supernatant was considered as the total protein extract and analyzed by SDS-PAGE followed by western blot, as follows. Samples were adjusted to 1% SDS, 0.3% 2-mercaptoethanol, 8.3% glycerol, 20 mM Tris–Cl, pH 8.6 and denatured by heating at 95°C for 4 min. SDS-PAGE was performed in 13% acrylamide gels using a Tris-glycine running buffer. After electrophoresis, proteins were transferred to nitrocellulose membrane (Protran, Whatman) using a Trans/glycine/methanol (25 mM/192 mM 20%, respectively) buffer in a wet electroblotting system (Trans-Blot® Cell, Bio-Rad). We verified that even protein polymers larger than 600 kDa are efficiently transferred using this protocol. Molecular weight markers (Fermentas) were used as molecular mass markers.

Yoo et al. 2007. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9. 18889:9-9.
SUBCELLULAR FRACTIONATION

Total microsomes were prepared as follows: leaf tissues were homogenized in a medium containing 50 mM Tris-acetate (pH 7.5), 250 mM sorbitol, 2 mM EGTA, 2 mM MgCl₂, 2 mM DTT supplemented with Complete. The homogenate was filtered and centrifuged at 10,000 × g for 10 min at 4°C. The supernatant was further centrifuged at 100,000 × g (rₑ) in a Beckman SW55Ti rotor (Beckman Instruments) for 30 min at 4°C. The resulting pellet, containing total microsomes, was resuspended in 10 mM Tricine-KOH (pH 7.5), 1 mM EGTA, 2 mM MgCl₂, 5% (v/v) sucrose, and was loaded on a sucrose-density gradient (10-40 mL, 15-45% w/v sucrose in 10 mM Tricine-KOH (pH 7.5), 1 mM EGTA and 2 mM MgCl₂), centrifuged at 77,000 × g (rₑ) for 19 h in a Beckman SW40 rotor and collected in 0.6 mL fractions. Equal volumes of each fraction were analyzed by SDS-PAGE followed by western blot with the appropriate antibody.

VELOCITY SUCROSE GRADIENT CENTRIFUGATION

Arabidopsis leaves (3-6 weeks old) were homogenized in ice-cold buffer containing 40 mM KCl or 200 mM NaCl, 2% Triton X-100, 50 mM Tris-Cl pH 7.8 (2 mg/g of leaf tissue), supplemented with Complete. Lysate was cleared by centrifugation at 700 × g for 10 min, loaded on a linear 5-25% (w/v) sucrose gradient (20 mM Tris-acetate, pH 7.5) and centrifuged at 200,000 × g (rₑ) for 25 h at 4°C in a Beckman SW40 rotor. An additional gradient was loaded with a mixture of molecular mass markers containing 200 μg each of cytochrome c (12.4 kDa), ovalbumin (43 kDa), bovine serum albumin (67 kDa), aldolase (161 kDa), and catalase (232 kDa). Equal volumes of each fraction were analyzed by SDS-PAGE followed by western blot with the appropriate antibody.

MICROSCOPY

Epifluorescence microscopy on plant tissues was performed using a Zeiss Axiosvert 200 microscope (Carl Zeiss) equipped for epifluorescence, followed by the collection of optical sections using Zeiss Apotome and Axiovision 4.1 software. Figures were assembled with Adobe Photoshop 10.0.

RESULTS

THE ABSENCE OF KCO3 CAUSES SLIGHT GROWTH DEFECTS UNDER OSMOTIC STRESS

Inactivation of the KCO3 gene could provide insights on the function of the protein. The Salk J96039 T-DNA insertion mutant was analyzed using T-DNA left border primer and KCO3-specific forward and reverse primers. Amplification was obtained with both primer pairs and showed a head-to-head T-DNA insertions at position 420 bp within KCO3 exon 1, as shown schematically in Figure 1. End-point PCR, with a couple of KCO3-specific primers, performed on genomic DNA from Arabidopsis T-DNA insertion line did not give rise to any product (Figure 1E, kco3-1), while a fragment of the correct length was obtained from wild-type plant DNA (Figure 1E, wt). The insertion line is therefore a full loss of function mutant and was termed kco3-1. Col-0 and kco3-1 seeds were sown on MS medium with 3% sucrose. Seven days after sowing, the seedlings were grown for 15 days on MS medium under long day conditions. No significant (Student’s t-test) differences were observed in root development, leaf number, and leaf size (Figure 2A). The response to osmotic stress or salt stress was tested by supplementing the MS medium with 100 mM mannitol or 75 mM NaCl. Mannitol caused a small but significant decrease of root growth in kco3-1 plantslets with respect to Col-0 (Figure 2B). This phenotype could be complemented by expressing a dominant-negative KCO3-mutant under control of the ANK03 promoter in the kco3-1 background (Figure 2B; dnKCO3; kco3-1). Expressing the dominant-negative mutant in the wild-type background had no beneficial effect for the plant (Figure 2B; dnKCO3). Upon NaCl treatment no difference was observed (Figure 2C). The effect of oxidative stress was tested by growing plantlets for 5 days in the presence of 10 mM H₂O₂. Both Col-0 and kco3-1 showed similar symptoms of bleaching and plant decay (Figure 2D). Finally, growth in medium supplemented with 100 μM K⁺ (K⁺ deficient) or 2.5 mM K⁺ (K⁺ sufficient) was analyzed (Figure 2E). No significant differences were observed in the mean values for increase in root length.

Altogether, these analyses indicate that the absence of KCO3 causes small defects in the early stages of plant growth under osmotic stress. These defects could be complemented by a dominant-negative mutant of KCO3.

KCO3 AND KCO3::GFP CONSTITUTIVELY EXPRESSED IN ARABIDOPSIS TRANSGENIC PLANTS LOCALIZE AT THE TONOPLAST

Endogenous expression levels of KCO3 are very low (Schönknecht et al., 2002, and see eFP developmental map: http://bbc.botany.utoronto.ca/eFP/cgi-bin/eFpWeb.cgi), hampering biochemical and cell biology studies. Arabidopsis transgenic plants expressing KCO3::GFP under the constitutive CaMV 35S promoter were therefore produced. Transgenic lines, selected on the basis of their kanamycin resistance, were tested for KCO3::GFP accumulation by western blot analysis of leaf extracts using anti-GFP antiserum (Figure 3A). Extracts from wild-type plants (Figure 3A, Co) did not react with the antiserum. A polypeptide with apparent molecular mass around 60 kDa was specifically detected in the kanamycin-resistant plants. This is in good agreement with the predicted mass of the fusion between KCO3 (29 kDa) and GFP (27 kDa), indicating that the 60 kDa polypeptide is intact and nearly intact KCO3::GFP (Figure 3A, KCO3::GFP). An additional polypeptide around 25 kDa was also detected in some of the transgenic plants, often when accumulation of KCO3::GFP was higher. Its molecular mass suggests that it corresponds to the kanamycin-resistant plants. This is in good agreement with the predicted mass of the fusion between KCO3 (29 kDa) and GFP (27 kDa), indicating that the 60 kDa polypeptide is intact and nearly intact KCO3::GFP (Figure 3A, KCO3::GFP). An additional polypeptide around 25 kDa was also detected in some of the transgenic plants, often when accumulation of KCO3::GFP was higher. Its molecular mass suggests that it corresponds to the entire or nearly entire GFP sequence, released from fusion protein (Figure 3A, plants 1, 2, 4, 11 – free GFP). Accumulation of KCO3::GFP in T1 and T2 generations was highly variable but it became stable in a number of T3 plants and generations. These plants did not show evident morphological and developmental differences compared to the wild-type. We reasoned that the detection of KCO3::GFP using the anti-GFP antiserum could limit our studies, because this does not allow to follow the destiny of KCO3 once GFP has been released. We therefore produced a specific antiserum against KCO3 (anti-KCO3) using as antigen 15 amino acids near the N-terminal end (residues 6–20). To test the specificity of this antiserum, equal amounts of total leaf homogenate from KCO3::GFP transgenic

FIGURE 2 | Phenotypic analysis of kco3-1. (A) Growth on MS medium supplemented with 3% sucrose. The wild-type and the kco3-1 knock-out mutant do not show significant differences in shoot development and root length. Figure is representative of three independent experiments. (B) Osmotic stress. The figure is representative of three independent experiments. Lower panel: increase in root length after 15 days. The values shown are mean of six repeats ± SD (indicated by error bars). Data were analyzed using Student’s t-test. The values obtained for kco3-1 are significantly different from those of the WT control, dnKCO3 and kco3-1 × dnKCO3 plants (P < 0.001). (C) Salt stress. Growth of Col-0 and kco3-1 plants was severely hampered by the presence of NaCl. The figure is representative for three independent experiments. Right panel: increase in root length after 15 days. The values shown are mean of six repeats ± SD (indicated by error bars). Student’s t-test revealed that Col-0 and kco3-1 are not significantly different (P > 0.1). (D) Oxidative stress. After five days of H2O2 stress, Col-0 and icc0-3 plants showed symptoms such as bleaching of leaves and plant decay. The figure is representative for two independent experiments. (E) K+ deficient and K+ sufficient medium. Lower panel: increase in root length after 15 days was plotted as means ± SD (indicated by error bars) of six repeats. Student’s t-test did not reveal any significant difference between Col-0 and kco3-1 (P > 0.1).
or control plants were subjected to SDS-PAGE and western blot with anti-GFP or the immuno-affinity purified anti-KCO3 antiserum (Figure 3B). No bands were visible in the control sample, consistent with the known very low endogenous expression level of KCO3. In the transgenic extract the anti-KCO3 antiserum specifically recognized two polypeptides around 60 and 120 kDa (Figure 3B, lane 2) were analyzed by western blot using anti-GFP antibodies. The positions of KCO3 (arrow) and an unspecific, cross-reacting polypeptide (asterisk) are indicated. In each panel, numbers on the left indicate the position and size (in kDa) of molecular mass markers.

**Figure 3B** Selection of Arabidopsis plants overexpressing KCO3::GFP and KCO3. (A) Equal amounts of leaf extracts (50 μg of total protein) from wild-type plants (Co), and independent transgenic Arabidopsis plants expressing KCO3::GFP (plants 1–11) were subjected to SDS-PAGE and western blot analysis with anti-GFP antiserum. The positions of the entire fusion protein and of free GFP are indicated. (B) Leaf extracts from one wild-type plant (lane 1) and transgenic plant 6 of panel A (lane 2) were analyzed by western blot using anti-KCO3 antibodies. The positions of monomers (arrowhead) and putative dimers (circles) are indicated. (C) Equal amounts (50 μg of total protein) of leaf extracts from wild-type (Col) or independent transgenic Arabidopsis plants overexpressing KCO3 (plants 2–7) were analyzed by western blot with anti-KCO3 antiserum. The positions of KCO3 (arrow) and an unspecific, cross-reacting polypeptide (asterisk) are indicated. In each panel, numbers on the left indicate the position and size (in kDa) of molecular mass markers.

The KCO3 polypeptides not completely denatured and still assem-bled into dimers. The ratio between these putative dimers and monomers was variable in different experiments. We tested different extraction and denaturation procedures, but we were unable to determine conditions in which such a variability could be avoided.

Having confirmed the ability of the antiserum to detect KCO3, transgenic Arabidopsis overexpressing KCO3 under the CaMV 35S promoter were prepared. Leaf homogenates were analyzed by SDS-PAGE and western blot with the anti-KCO3 antiserum. A polypeptide with apparent molecular mass around 30 kDa, consistent with the 29 kDa calculated mass of KCO3, was detected in the transgenic lines but not in control plants (Figure 3C, plants 2–7 and Co, respectively). A polypeptide around 20 kDa was also detected in both control and KCO3 plants (Figure 3C, asterisk); however, this was not related to KCO3, because it was also recognized by the pre-immune serum (not shown). We propagated line 6 from T3 generation, but also in T4 the accumulation levels of KCO3 were variable. We were unable to obtain a line giving constant KCO3 levels in the progeny, possibly because of transgene silencing.

The subcellular localization of KCO3::GFP was analyzed by epifluorescence microscopy in leaf and hypocotyl tissues (Figure 4). In leaf epidermal cells, GFP fluorescence was clearly detected on the tonoplast (Figures 4A–C). In different cells, the GFP fluorescence appeared either continuous or irregularly distributed on the tonoplast, with several highly fluorescent “spots.” No colocalization with the plasma membrane was observed when the GFP and the brightfield images were superimposed (Figures 4D–I). The tonoplast localization was also observed in hypocotyl cells (Figures 4D–F). The results were confirmed by subcellular fractionation followed by western blot. Total microsomes were prepared from KCO3::GFP or KCO3 leaf homogenates, loaded onto a continuous sucrose gradient and subjected to isopycnic ultracentrifugation (Figure 5). The distributions of KCO3::GFP, KCO3, and the tonoplast aquaporin γTIP were similar and they markedly differed from those of the plasma membrane aquaporin PIP2 or the endoplasmic reticulum marker endoplasmic reticulum-associated protein 94 (Figure 5). The results were confirmed by subcellular fractionation followed by western blot. Total microsomes were prepared from KCO3::GFP or KCO3 leaf homogenates, loaded onto a continuous sucrose gradient and subjected to isopycnic ultracentrifugation (Figure 5). The distributions of KCO3::GFP, KCO3, and the tonoplast aquaporin γTIP were similar and they markedly differed from those of the plasma membrane aquaporin PIP2 or the endoplasmic reticulum marker endoplasmic reticulum-associated protein 94 (Figure 5). The results were confirmed by subcellular fractionation followed by western blot.
membrane (VK channel; Gobert et al., 2007; Lätz et al., 2007). Furthermore, the activity of VK channels is stimulated by acidic cytosolic pH (Allen et al., 1998; Gobert et al., 2007). Consequently, we probed KCO3 activity by recording membrane currents from isolated vacuoles successively exposed to four different experimental conditions, varying the cytosolic Ca\(^{2+}\) concentration (low versus high Ca\(^{2+}\)) at two cytosolic pH values (pH\(_{cyt}\) 7.5 and pH\(_{cyt}\) 6.5). As summarized in Figure 6, the current densities of KCO3-overexpressing vacuoles were almost identical to those determined for wild-type vacuoles at either pH\(_{cyt}\). Increases of cytosolic [Ca\(^{2+}\)] generally caused only minor changes in the current amplitudes: the slight decrease at pH\(_{cyt}\) 7.5 (Figure 6C) was possibly due to a further reduction of residual FV channel activity, while the small increase at pH\(_{cyt}\) 6.5 (Figure 6F) may correspond to the activation of a small population of VK channels.

In summary, these data strongly suggest that KCO3, present in the vacuolar membrane of overexpressing plants, does not constitute a functional ion channel in our experimental conditions.

**KCO3 and KCO3::GFP are Detected as Dimers**

The formation of a tetrameric complex is a prerequisite for ion channel activity in the case of the one-P subunit KCO3. We therefore investigated on the oligomerization state of KCO3 and KCO3::GFP Total leaf homogenate from KCO3::GFP plants was fractionated by velocity sucrose gradient centrifugations in the presence of non-ionic detergent. Using this assay, we have previously confirmed that TPK1::GFP is a dimer, as expected (Maîtrejean et al., 2011). Equal volumes of fractions were analyzed by western blot with anti-GFP (Figure 7A) or anti-KCO3 (Figure 7B) antisera. KCO3::GFP sedimented slightly slower than the 150 kDa marker, indicating a dimer of the 60 kDa polypeptide. Each gradient fraction contains a similar ratio between polypeptides that are fully denatured upon SDS-PAGE and polypeptides that remain assembled into putative dimers (Figures 7A,B, fractions 9–12). The co-migration of the two forms along the gradient strongly suggests that the component around 120 kDa really represents dimers. No polypeptides recognized by anti-GFP or anti-KCO3 antisera peaked in the expected position of putative tetramers (their migration should be slightly faster than the 232 kDa marker). Free GFP released from the fusion protein migrated as a monomer and was recognized by the anti-GFP antiserum (Figure 7, compare Figure 7A and Figure 7B, fractions 4–5). This strongly suggests that the GFP moiety does not have a role in the dimerization of KCO3::GFP. The same behavior had been observed for free GFP released from TPK1::GFP (Maîtrejean et al., 2011). Partial proteolysis also seems to occur, as indicated by the additional bands detected below the major 66 kDa band.

To exclude that GFP appended at the C-terminal end of KCO3 impaired tetramerization, velocity gradient centrifugation analysis was performed on leaf extracts from KCO3 transgenic plants. Fractions were analyzed by western blot with anti-KCO3 antiserum. KCO3 sedimented slightly slower than the 67 kDa marker (Figure 7C, fractions 7–9), indicating that also the wild-type protein is a dimer in the conditions used in our analysis. We then tested whether the assembly grade of another
multispanning tonoplast protein was preserved in our assay. Western blots of gradient fractions were therefore visualized with anti-γTIP antiserum. γTIP, which is a tetramer, peaked as expected between the 67 and 150 kDa markers (Figure 7D, fractions 9–10). We conclude that our experimental conditions preserve the correct assembly of another multispanning tonoplast protein.

It has been previously reported that tetramerization of the viral K⁺ channel Kcv was perturbed in the presence of a high concentration of sodium ions, but was maintained if 40 mM...
FIGURE 6 | Current density versus voltage characteristics recorded in different experimental conditions from vacuoles of Arabidopsis wild-type and KCO3-overexpressing plants. (A–C) Current density–voltage relationships recorded in the whole-vacuole configuration (see Figure A1) from vacuoles of Arabidopsis wild-type (open blue symbols) and KCO3-overexpressing plants (filled red symbols). Bath solutions of pH 7.5 contained either low calcium (A) or high calcium (B). The current density difference (Ddif) between high and low calcium conditions was calculated for individual vacuoles and averaged (C). (D,F) As in (A–C), but in bath solutions of pH 6.5, in low calcium (D), in high calcium (E), difference (F, Ddif). In each panel, the number of WT or KCO3 vacuoles analyzed is given in brackets.
FIGURE 7 | KCO3::GFP and KCO3 are dimers. Leaves from KCO3::GFP (A,B,D–F) or KCO3 (C,G) transgenic Arabidopsis plants were homogenized in the presence of non-ionic detergent and either 200 mM NaCl (A–D) or 40 mM KCl (E–H). The homogenates were then subjected to sedimentation velocity centrifugation on a continuous 5–25% (w/v) sucrose gradient. One-tenth of the total volume of each gradient fraction were analyzed by SDS-PAGE and western blot using anti-GFP antiserum to detect KCO3::GFP (A,E), anti-KCO3 antiserum to detect KCO3::GFP (B,F) or KCO3 (C,G), anti-γTIP (D,H). Top of each gradient is at left. Numbers on top indicate the position along the gradient and the molecular mass (in kDa) of sedimentation markers. Numbers at left indicate the positions of SDS-PAGE molecular mass markers.

KCl was used instead of 200 mM NaCl (Pagliuca et al., 2007). We therefore analyzed the assembly state substituting NaCl with KCl in the homogenization and gradient buffers. Neither tetramers or monomers of KCO3::GFP and KCO3 could be detected, and the assembly state of γTIP was not altered as well (Figures 7E–H).

Therefore, stable KCO3 or KCO3::GFP homodimers are detected in experimental conditions in which the related TPK1 protein and the other multispanning tonoplast protein γTIP maintain their correct assembly properties. This indicates that KCO3 tetramers are either held together by weaker or very transient interactions, or are never formed.
A. thaliana, which has remained enigmatic until now.

The features of the kco3-1 null-allele mutant observed in the presence of mannitol indicate that under certain conditions KCO3 exhibits a small effect on root elongation. The absence of KCO3 could be compensated by a dominant-negative version of this subunit. This indicates that, whatever the function of KCO3, it does not depend on putative direct ability to transport ions. It is however clear that in most conditions no significant alteration in growth was detected.

Using transgenic plants expressing the KCO3 gene or a KCO3::GFP fusion constructs under the control of the constitutive CaMV 35S promoter, we confirmed and extended to stable transgenic Arabidopsis previous results from transient expression experiments (Voelker et al., 2006) on the tonoplast localization of KCO3. Patch-clamp recordings were therefore performed on vacuoles isolated from KCO3-overexpressing plants, in order to provide evidence of ion channel activity. In the design of these experiments, we started from the idea that KCO3 activity may be regulated, either positively or negatively, by cytosolic vacuoles. In similar working conditions, TPK1 activity was detected both in transfected yeast cells (Latz et al., 2007) and overexpressing Arabidopsis plants (Gobert et al., 2007).

The failure to obtain evidence for changes in current in the overexpressing plants prompted us to investigate on the KCO3 assembly status. To be active as a cation channel, KCO3 must either form homotetramers or contribute to the formation of a hetero-oligomer with four P-domains in total. However, we have only been able to detect homodimers of KCO3 or KCO3::GFP, in line with its evolutionary origin from dimeric TPK channels. The fact that both recombinant proteins, which have quite different molecular masses, migrate along velocity gradients at the positions expected for the corresponding homodimers rules out the possibility that the forms we detect are hetero-oligomers containing other unknown polypeptides. We have previously used this velocity centrifugation assay to study the assembly state of wild-type or different mutated forms of TPK1 fused to GFP (Maitrejean et al., 2011). Constructs unable to traffic along the secretory pathway, and therefore with incorrect subunit interactions, could be distinguished by the assay from correctly assembled dimeric TPK1::GFP (Maitrejean et al., 2011). This indicated that wrongly assembled forms of a tandem-pore channel are unable to traffic and that the incorrect interactions can be detected by the velocity centrifugation assay. The tonoplast localization of KCO3 and KCO3::GFP in transgenic Arabidopsis instead indicates that these proteins traffic along the secretory pathway and are therefore not recognized as defective proteins by the endoplasmic reticulum quality control.

The stable assembly of a dimeric form of a cation channel subunit with one P-domain is thus compatible with traffic, but it is clearly incompatible with activity. KCO3 is not the only Arabidopsis K+ channel that does not show activity. AtKC1, which belongs to the Shaker-like family is also inactive, but, unlike KCO3, remains located in the endoplasmic reticulum when overexpressed alone (Dreyer et al., 1997; Duby et al., 2008). Interaction of AtKC1 with other Shaker-like subunits allows the formation of traffic-competent, active heterotetramers with differences in activity compared to the respective homotetramers. AtKC1 thus acts as a modulator of channel activity. Furthermore, it has been shown that these heterotramers can be further regulated by interaction with the SYP112 protein SYP112 at the plasma membrane (Honsbein et al., 2009). KCO3 could in theory have a regulatory function by interacting with TPK subunits. Such an interaction could escape our assembly assay because of its transient or weak nature. Possibly, the formation of heteromers with KCO3 would prevent these TPK subunits from proper assembly into functional channels and expression of KCO3 would then have a modulatory function on certain tandem-pore channels. Although such a regulation does not appear to be very efficient, it might nevertheless be useful in fine-tuning the permeability of the tonoplast for K+ ions and would be consistent with the minor but detectable growth phenotype of the null allele that was complemented by a dominant-negative version of KCO3. However, it should be taken into consideration that, unlike AtKC1, overexpressed KCO3 traffic along the secretory pathway also in the absence of co-expressed putative partner subunits. Its tissue expression overlaps mostly with that of TPK3, but fluorescence transfer and bimolecular fluorescence complementation experiments failed to detect heteromeric interactions between KCO3 and TPK1 or TPK3 (Voelker et al., 2006). Heteromeric interactions seem therefore very unlikely, even if our results do not exclude that KCO3 actually forms a homotramer by interactions that are not preserved in our conditions. Indeed, tetramers of Kcv, a viral K+ channel with one pore domain per subunit, are disrupted when K+ is substituted by Na+ or Li+ in the assay buffer. This disruption results in full Kcv disassembly into monomers, without the production of detectable dimers (Pagliuca et al., 2007). This supports the hypothesis that KCO3 dimers detected in the present study are stable, natural forms of this one P-subunit.

Recent fluorescence fluctuation analysis in transfected CHO cells suggested that human vanilloid receptor 1 (TRPV1), which belongs to the superfamily of cation channels with six transmembrane segments and one P-region, exists in two oligomerization states: dimeric in basal conditions and tetrameric upon activation (Stoore et al., 2012). Similarly, it is possible that KCO3 dimers further assemble very transiently and reversibly or only upon certain physiological conditions: if only a very minor proportion of polypeptides were involved in this process at a given time, this could be below our detection limit. The process of further assembly could also require the presence of an additional factor. 14-3-3 proteins are among the candidates, since physical interaction and activity stimulation has also been shown for TPK1 (Latz et al., 2007).
In any case, our results indicate that KCO3 homodimers are as stable as TPK1 homodimers in the extraction and analysis conditions. The formation of KCO3 channels, at least part of the interactions involved must be different from those that hold together dimers. The search for such putative interactions would need further experimental approaches.

ACKNOWLEDGMENTS

We thank Christophe Maurel and Natasha Raikhel for the gift of anti-PIP and anti-β-tubulin antisera. We are grateful to Marie Maîtrejean for the useful discussions and suggestions. Study supported by the EU Marie Curie Research Training Network “Vacuolar Transport Equipment for Growth Regulation in Plants” (MRTN-CT-2006-035833) and by the 2008 “Progetti di Ricerca di Interesse Nazionale” to Armando Carpenato. Tripti Sharma was member of the Max-Planck Research School “Primary Metabolism and Plant Growth” at the University of Potdam and the Max-Planck Institute of Molecular Plant Physiology (Potsdam-Golm) and received a fellowship of the German Academic Exchange Service (DAAD). Ingo Dreyer is supported by a Marie Curie Career Integration Grant (FP7-PEOPLE-2011-CIG No. 303674 – Regopoc) of the EU.

FIGURE A1 | Current traces recorded in whole-vacuole mode in vacuoles isolated from Arabidopsis mesophyll cells. (A) Current traces recorded 2 min after achieving the whole-vacuole configuration in response to voltage steps from +80 to −80 mV, step −20 mV. The holding and tail voltages were 0 and −50 mV, respectively. The vacuole had a capacitance of 34 pF and derived from an Arabidopsis wild-type plant. (B) Current traces recorded from the same vacuole as in A, 20 min after the break-in.
