ABSTRACT

Background: Tubercular atlantoaxial, rotatory dislocation warranting fixation (AARF) is an extremely rare event.

Case Description: AARF was suspected in a 23-year-old female with painful torticollis. When diagnostic studies documented unilateral destruction of the left lateral mass of the atlas, she underwent removal of the lateral mass, reduction of the deformity, and C1–C2 fusion/reconstruction utilizing an iliac bone graft. Laboratory tests and the pathologic surveys were all consistent with the diagnosis of underlying tuberculosis.

Conclusion: We present a case of tubercular atlantoaxial, rotatory dislocation (AARF) in a patient who warranted C1–C2 decompression, reduction, and fusion.

Keywords: Atlantoaxial dislocation, Atlantoaxial rotatory fixation, Atlas, Craniovertebral junction, Tuberculosis, Upper cervical

INTRODUCTION

Tuberculosis (TB) involving the atlantoaxial complex is rare, accounting for approximately 0.1% of all spinal tubercular infections.[1,3,5,11,14] Here, we present a young woman with painful torticollis attributed to tubercular atlantoaxial rotatory dislocation (AARF).

CASE REPORT

A 23-year-old female presented with a 4-week history of severe neck pain (VAS:10) and torticollis with a classic “Cock Robin” deformity. Laboratory studies demonstrated an increased erythrocyte sedimentation rate (ESR) of 42. The lateral cervical plain radiographs and computed tomography (CT) axial, 2D, and 3D reconstructed images showed C1–C2 AARF with destruction of the left lateral mass of the atlas [Figures 1-4]. The integrity of the vertebral artery at C1–C2 was also critically confirmed on the preoperative CT angiogram (CTA) [Figure 5].

Surgery

As cervical traction failed to reduce the deformity, surgical intervention was warranted. Surgery required; the initial insertion of bilateral C2 pedicle screws, isolation of the V3
segment of the vertebral artery, removal of the destroyed left C1 lateral mass in a piecemeal fashion, and fusion (e.g., utilizing a tricortical iliac bone graft secured with left C1 laminar hook-C2 pedicle screw, and an additional right C1 lateral mass-C2 pedicle screw rod construct) [Figure 6]. Postoperatively, the patient's torticollis and intractable pain resolved. X-rays taken 1 week, and 3 months after surgery demonstrated adequate alignment of the instrumentation/construct [Figure 7]. Three years later, the patient is asymptomatic [Figure 8].

**Bacteriology and pathology**

The operative specimens demonstrated: a positive polymerase chain reaction (PCR) for TB, and the pathology was compatible with a granulomatous infection.

**Tubercular treatment**

Four-drug therapy was warranted for TB; isoniazid (5 mg/kg), rifampicin (10 mg/kg), ethambutol (15 mg/kg), and pyrazinamide (25 mg/kg). They were administered as a first-line of treatment for 4 months. This was followed by an additional 12 months of rifampicin and isoniazid.

**DISCUSSION**

Spinal TB, presenting as AARF with painful torticollis, is extremely rare.

**Pathogenesis**

Severe painful torticollis may be the only clinical indication that AARP is present. Patients may exhibit unilateral destruction of the lateral mass of the atlas with/without infiltration/disruption of the alar ligaments. The ESRs are typically increased, and the Mantoux test is typically positive. Further, acid-fast stains of pathological material, positive cultures, and PCR obtained through CT-guided biopsy may be additional valuable adjuncts to confirm the diagnosis of TB.

**Imaging**

AARF is the best documented utilizing axial reconstructed 2D and 3D CT images and CTA. The following findings are classical for TB: an osteolytic, fragmented lesion involving the C1 lateral mass, deviation of the odontoid to the affected lateral mass side, and forward displacement of the contralateral lateral mass of atlas.

Magnetic resonance imaging also may help to establish the diagnosis of tuberculous involvement of the C1 lateral mass,

by demonstrating heterogeneous intensity on the T1, and hyperintensity on the T2-weighted and fat-suppressed images.

**Differential diagnosis**

The differential diagnoses for painful torticollis with unilateral involvement of the C1 lateral mass include TB tumors, rheumatoid arthritis, and other types of pyogenic spondylitis.\(^{[4,6,7,8,10,13,15]}\)

**Management**

In classic tubercular atlantoaxial dislocation, management strategies range from purely conservative treatment to radical operations.\(^{[1,3,11,14]}\) Surgical intervention for decompression, reduction/realignment, and instrumented fusion may also be warranted.
CONCLUSION

Here, we presented an extremely rare cause of painful torticollis due to tubercular AARF involving a unilateral C1 lateral mass requiring decompression, reduction, and fixation.
