Relativistic Aharonov-Casher Phase in Spin One

James A Swansson‡ and Bruce H J McKellar§

School of Physics, University of Melbourne,
Parkville, Victoria, Australia, 3052

Abstract.

The Aharonov-Casher (AC) phase is calculated in relativistic wave equations of spin one. The AC phase has previously been calculated from the Dirac-Pauli equation using a gauge-like technique [1, 2]. In the spin-one case, we use Kemmer theory (a Dirac-like particle theory) to calculate the phase in a similar manner. However the vector formalism, the Proca theory, is more widely known and used. In the presence of an electromagnetic field, the two theories are ‘equivalent’ and may be transformed into one another. We adapt these transformations to show that the Kemmer theory results apply to the Proca theory. Then we calculate the Aharonov-Casher phase for spin-one particles directly in the Proca formalism.

1. Introduction

The Aharonov-Casher phase is often linked, perhaps subconsciously, with the Aharonov-Bohm phase. There is a common misconception that the AC phase is the dual of the AB phase, but there are important physical and conceptual differences between them.

For the latter, the absence of any classical field local to the position of the particle makes the force-free nature of the origin of the phase only too evident. For the former, however, the situation is reversed, the particle is all too clearly in the presence of the electric field, and Aharonov and Casher were not too perspicuous about the origins of the force-free effect. Subsequently much debate has revolved about this issue [3, 4, 5].

At an early stage of this debate a concise letter by Goldhaber [3] spelled out the differences between the two effects. These were, in addition to the obvious difference that the particle is located in the field, that

(i) whereas in the AB effect the flux, although infinitely long, may be curved arbitrarily, in the AC effect the line charge must be straight and parallel to the magnetic moment, and

(ii) there is an extra degree of freedom in the AC effect, viz the spin orientation, which adds a special interest, particularly when considered in the quantum mechanical context.

The first observation, while correct in saying that the force-free phase arises out of a particular configuration of the particle and field, is not yet the full story. It was not until much later [1, 2, 6, 7] that it was explicitly noted that this configuration also required that the magnetic moment of the particle is perpendicular to the plane of its motion.

The necessity of these conditions can be demonstrated by briefly reviewing the relativistic derivation of the phase of He and McKellar in Ref. [1]. This derivation has the advantage that the assumptions necessary for the AC phase to appear as an exact result are made explicit, whereas the original derivation, based on the Schrödinger equation used a weak field approximation which obscured some of the assumptions. The Dirac-Pauli equation of a charge zero particle with an anomalous magnetic moment in an electromagnetic field

\[ (i\gamma^\mu \partial_\mu + \frac{1}{2}\mu\sigma_{\alpha\beta}F^{\alpha\beta} - m)\psi = 0. \]  

is to be transformed into the free Dirac equation for a wave-function \( \psi' \) which differs from \( \psi \) by a phase: \( \psi' = e^{i\chi}\psi \). The Dirac equation for \( \psi' \), when written in terms of \( \psi \),

\[ (i\gamma \cdot \partial - m)e^{i\chi}\psi = 0, \]  

will contain derivatives of the position dependent phase \( e^{i\chi} \), which will generate interaction terms in the equation for \( \psi \). For these interactions to have the correct Pauli form the phase \( \chi \) must be a path ordered line integral of a field linearly related to the field

\[ F^{\mu\nu} \]  

We consider the case where the field \( F^{\mu\nu} \) is a pure electric field, with \( F^{0i} = E_i \) the only non-vanishing components.
the electric field, and must also have an appropriate Dirac matrix dependence. For the phase, make the anzatz

\[ \exp i\chi = \mathcal{P} \exp i\Gamma \gamma^0 \mu \int \vec{A}' \cdot d\vec{r}', \]

(3)

where \( \Gamma \) is an appropriate element of the Clifford algebra generated by the Dirac matrices, and \( \vec{A}' \) is an effective “vector potential”, related to the electric field, and \( \mathcal{P} \) indicates path ordering of the integral in the phase. Both \( \Gamma \) and \( \vec{A}' \) are to be determined from the condition that the equation (2) generates the equation (1).

By eliminating the constant phase component after the operation of the derivative the conditions for the equivalence of (1) and (2) are then

\[ e^{-i\chi} \gamma^\nu e^{i\chi} \partial_\nu \psi = \gamma^\nu \partial_\nu \psi, \]

(4)

\[ e^{-i\chi} \gamma^\nu e^{i\chi} \partial_\nu \psi = \mu \sigma^{\alpha\beta} F_{\alpha\beta}. \]

(5)

Making use of the Baker-Hausdorff formula

\[ e^{-i\lambda \xi^3} \beta^\mu e^{i\lambda \xi^3} = \beta^\mu + \mathcal{P} (-i\lambda) [\xi_3, \beta^\mu] + \frac{1}{2!} \mathcal{P} (-i\lambda)^2 [\xi_3, [\xi_3, \beta^\mu]] \ldots, \]

(6)

the condition (4) can be expressed in terms of a commutation condition,

\[ [\gamma^\nu, \Gamma \gamma^0] \partial_\nu \psi = 0 \]

(7)

which can be satisfied only if the operator \( \Gamma \) is the product of two spatial gamma matrices, say \( \Gamma = \gamma^1 \gamma^2 \), and the wave-function is independent of the spatial co-ordinate corresponding to the the gamma matrix which does not appear in this equation. In this case, \( \partial_3 \psi = 0 \). For future use we note that we may rewrite

\[ i\Gamma \gamma^0 = \gamma_5 \gamma^3 \]

(8)

which is the operator which has as eigenstates those states with well defined components of the spin in the 3 direction, when the motion of the particle is normal to the 3 direction [8].

The choice of the operator \( \Gamma \), with equation (2), then means that the term \( \gamma^i \gamma^1 \gamma^2 \gamma^0 A'_i \) must be \( \sigma^{0j} E_j \), ie

\[ A'_1 = -E_2, \quad A'_2 = E_1 \]

(9)

which may be conveniently written as

\[ A'_i = -\varepsilon_{ij} E_j \]

(10)

with \( \varepsilon_{ij} \) the two component antisymmetric tensor with the value \( \varepsilon_{12} = +1 \).

This derivation clearly shows that the dynamics are restricted to \( 2 + 1 \) dimensions through the conditions \( \partial_\perp \psi = 0, \ E_\perp = 0, \ \partial_\perp E_\perp = 0 \), apply, and \( \psi \) is an eigenstate of \( \sigma_\perp \), where subscript \( \perp \) indicates the coordinate perpendicular to the plane of motion [1].

The wave function \( \psi \) is related to the solution of the free equation (2) by a well defined, coherent phase. Therefore we infer that it does not alter any kinematic properties of the solution. The interaction so isolated can therefore be referred to \footnote{We define \( \gamma_5 = i\gamma^0 \gamma^1 \gamma^2 \gamma^3 \). Note we will also omit further reference to path ordering for simplicity.}
as ‘force-free’. A particle with zero charge but with an anomalous magnetic moment will accumulate a topological phase, when a strict configuration of velocity, magnetic moment and the line of charge is is satisfied. This will be referred to as the AC configuration.

Because these conditions have been shown to lead to the AC phase without approximation only for a Dirac particle, yet we know from the original non-relativistic approach that they lead to the AC phase in the weak field approximation for arbitrary spin, we ask whether it is possible to extend the exact derivation to relativistic higher spin systems. Here we take the first step in providing an answer to that question by showing that the derivation of reference [1] can indeed be extended to the relativistic spin one particle.

2. Aharonov-Casher phase in Spin one

2.1. The Kemmer Theory

This method exploits the genuine first order nature of the Dirac theory, where the derivative of the path-dependent phase produced terms linear in the field strengths, and hence comparable to the elements of the Dirac-Pauli interaction term. So naturally we extend this method to spin one using the first order Kemmer spinor theory [9].

The 16 dimensional spin one spinor $\phi$ has a Dirac-like free equation of motion,

$$(i\beta^\mu \partial_\mu - m) \phi = 0,$$

where the $\beta$-matrices are generalizations of the Dirac gamma matrices. These satisfy an algebra ring, which for spin one is

$$\beta^\lambda \beta^\mu \beta^\nu + \beta^\nu \beta^\mu \beta^\lambda = \eta^{\lambda \mu} \beta^\nu + \eta^{\mu \nu} \beta^\lambda.$$  

These Kemmer $\beta$-matrices are reducible, that is the $16 \times 16$ representation decomposes into three separate representations: a one dimensional trivial representation; a 5-d spin zero representation; and the 10-d spin one representation. Of course these each satisfy (12) separately. It is also noteworthy that this algebra ring is ‘odd’, that is it cannot reduce the matrix operator to the identity, unlike the Dirac algebra.

Just as in Dirac theory, the Lorentz invariance of the Kemmer theory entails a transformation of the spinor so that the matrix representation remains the same. The Lorentz generator for these transformations, $S_{\mu \nu}$, like its spin 1/2 equivalent $\sigma_{\mu \nu}$, is proportional to the antisymmetric product of two matrices of the ring:

$$S_{\mu \nu} = b(\beta_\mu \beta_\nu - \beta_\nu \beta_\mu)$$

These generators satisfy well known commutation relations (see Refs. [10, 11]) and define the spin operators. The coefficient $b$ is linked to the coefficient in the Lorentz transformation, and hence to the coefficient of the commutation relations, and is set below according to our convenience.
The equation of motion of a spin one neutral particle with an anomalous magnetic moment in Kemmer theory is

\[ \left( i \beta \mu \partial_\mu + \frac{1}{2} \mu S_{\alpha \beta} F^{\alpha \beta} - m \right) \phi = 0. \]  

The interaction term does emerge from the derivation of a ‘2nd order Kemmer equation’ following the method of Umezawa [11, 12], however we rely on the reduction of this term to its non-relativistic equivalent to confirm this form as well as fix the ambiguity in coefficients outlined above. In particular this is done so that the sought-for phase can be compared with its 1/2 equivalent. We also note in advance that this term is transformed into its equivalent in Proca theory [10].

The operator component of the phase in the spin 1/2 AC phase solution was found to be a pseudo-vector spin operator. This operator can be re-written as the anti-symmetric product of three matrices of the Dirac algebra, which suggests we adopt a spin one pseudo-vector operator defined by

\[ \xi_\mu = \frac{i}{2} \varepsilon_{\mu \nu \lambda \rho} \beta^\nu \beta^\lambda \beta^\rho, \]  

This is easily verified to be a spin operator in the rest frame.

Now a path dependent phase proportional to \( \xi_3 \) is introduced in the free Kemmer equation of motion (11),

\[ (i \beta \mu \partial_\mu - m) e^{i \xi_3 \int^r \vec{A}' \cdot d\vec{r}} \phi = 0, \]  

with the intention to transform this into the equation of motion (13) with the anomalous magnetic moment term. Allowing the operators to act on the solution \( \phi' \), and eliminating the phase supplies two conditions:

\[ e^{-i \xi_3 \int^r \vec{A}' \cdot d\vec{r}} \beta^\mu e^{i \xi_3 \int^r \vec{A}' \cdot d\vec{r}} = \beta^\mu, \]  
\[ -\beta^\mu \xi_3 A'_m \phi = \frac{1}{2} \mu S_{\alpha \beta} F^{\alpha \beta} \phi = \mu S_{\alpha l} F^{\alpha l} \phi. \]

Making use of the Baker-Hausdorff formula, the first condition reduces to the requirement that the commutator is zero. If \( \mu \neq 3 \) then this is automatically satisfied, however for \( \mu = 3 \), inspection of the definition of \( \xi_3 \) and the \( \beta \)-algebra will show that the commutator does not vanish. Thus in order to satisfy the first condition the dynamics of the system are restricted to 2 + 1 dimensions, just as for spin half in Ref [11]. In particular \( \partial_3 \phi \) and \( A'_3 \) are zero.

Of the second condition, consider first the operators of the LHS. For \( \mu = 0 \) we get a solution which corresponds to \( F_{12} \), which the sake of this calculation is zero. For \( \mu = 1, 2 \) we have (repeated indices are no longer summed):

\[ -\beta^\mu \xi_3 = \beta_\mu \xi_3 = -\epsilon_{\mu \nu \rho} \frac{1}{2} S_{0 \nu} \beta^2_\mu \left( = -\epsilon_{\mu \nu \rho} \frac{1}{2} \beta^2_\mu S_{0 \nu} \right), \]  

where \( \epsilon_{\mu \nu} \) is an antisymmetric tensor with \( \epsilon_{12} = 1 \). Then for \( \mu = 1, 2 \) the action of \( \beta_\mu \) on (18) gives

\[ -\frac{1}{2} \eta_{\mu \nu} \epsilon_{\mu \nu} \beta_\mu S_{0 \nu} = +\frac{1}{2} \epsilon_{\mu \nu} \beta_\mu S_{0 \nu}. \]
Employing this, the definition of $\xi_3$ and the $\beta$-algebra,
\[
s_3 S_{0\nu} \beta_\mu^2 \phi_s = -S_{0\nu} s_3 \phi_s,
\]  
(20)
where the states $\phi_s$ are eigenstates of the spin operator $\xi_3$. Then it follows that $S_{0\nu} \beta_\mu^2 \phi_s$ equals $-S_{0\nu} \phi_s$, hence for the operators of the LHS of (17) acting on $\phi_s$ equal $\frac{1}{2} \epsilon_{\mu\nu} S_{0\nu} \phi_s$ for any value of $s_3$. Now the comparison of these terms with the those of the Dirac-Pauli interaction term in the RHS of (17) yields the field conditions:
\[
A'_1 = -2\mu E_2 \quad A'_2 = 2\mu E_1 \quad E_3 = 0
\]  
(21)
Clearly given that $E_3 = 0$, and adding the further restriction that $\partial_3 E_3 = 0$, then the curl of $\vec{A}'$ is equal to $2\mu \nabla \cdot \vec{E}$. When the particle is moved around a closed path in this configuration the AC phase is given by,
\[
\phi_{AC} = \xi_3 \oint \vec{A}' \cdot dr = 2\mu \xi_3 \int_S (\nabla \cdot \vec{E}) \cdot dS = 2\mu \xi_3 \lambda,
\]  
(22)
where $\lambda$ is the line density of charge. The conditions for the AC effect with spin one particles are exactly those for spin 1/2, except that the spin operator and spinor have changed. The factor of two shows that the phase is twice that accumulated by a spin half particle with the same magnetic moment coupling constant, in the same field.

2.2. Equivalence of AC Phase in Proca Theory

For the description of spin one particles, however, the Kemmer theory is not as widely known nor used as the Proca wave equations. Moreover these two theories are equivalent in the sense that, including the electromagnetic interactions, they can be transformed into one another [10]. Therefore we should like to demonstrate that the results obtained above are the same as those obtainable in Proca theory. However in Proca theory which, being inherently a second order theory, produces derivatives of the fields which are not present in the electromagnetic interaction at this order, this phase technique ‘fails’. So as a first step we demonstrate this equivalence by the transformation of the AC phase obtained in the Kemmer theory into the Proca formalism.

The transformation from the Kemmer to the Proca formalism is usually introduced in the context of selecting projection operators which pick out the spin one irreducible representation from the $\beta$-matrices [10]. These operators then reproduce the Proca equation. The projection matrices $U^\mu$ and $U^{\mu\nu}$ are constructed from the $\beta$-matrices:
\[
U^\mu = -(\beta^1)^2(\beta^2)^2(\beta^3)^2(\beta^\mu \beta^0 - \eta^{\mu0}),
\]  
\[
U^{\mu\nu} = U^\mu \beta^\nu = -U^{\nu\mu},
\]  
\[
U^\mu \beta^\nu \beta^\sigma = \delta^{\nu\sigma} U^\mu - \delta^{\mu\sigma} U^\nu
\]  
(23)
(24)
(25)
The four vector components of the Proca theory $\psi^\nu$, and six field components $G^{\mu\nu}$ are defined respectively by the relations
\[
U^\nu \phi = i \sqrt{m} \psi^\nu, \quad U^{\mu\nu} \phi = \frac{1}{\sqrt{m}} G^{\mu\nu}.
\]
Then the operation of $U^{\mu\nu}$ on the Kemmer equation yields the anti-symmetric field tensor expressed in terms of the vector components,

$$G^{\mu\nu} = \partial^\mu \psi^\nu - \partial^\nu \psi^\mu.$$  \hspace{1cm} (26)

while the operation of $U^\nu$ on the Kemmer equation yields the Proca equation:

$$\partial_\mu G^{\mu\nu} + m^2 \psi^\nu = 0.$$  \hspace{1cm} (27)

At this stage we merely comment if the Kemmer spinor is modified by a simple (c-number, path-independent) phase, $e^{i\lambda \phi}$, then these transformations produce a Proca vector, $e^{i\lambda \psi^\nu}$, and field tensor, $e^{i\lambda G^{\mu\nu}}$, similarly modified by this phase.

Earlier we indicated that the anomalous magnetic moment term which in eq. (13) was expressed in terms of the Lorentz operator $S_{\mu\nu}$ contains an ambiguity. Therefore, in the following, it is convenient to drop the notation of equation (13) and express the anomalous magnetic moment in its ‘absolute’ form using the commutator of $\beta$-matrices

$$i\mu [\beta^\mu, \beta^\nu] F_{\mu\nu}.$$  

The transformation of this term yields $-2im\mu (F_{\sigma\mu}\psi^\sigma)$. This can be compared with that derived from the introduction of minimal coupling in the Proca equations or with the standard anomalous interaction form:

$$i\mu m \hat{I}^{\mu\nu}_{\alpha\beta} F_{\mu\nu} \psi^\beta = i\mu m \left( g^\mu_{\alpha} g^\nu_{\beta} + g^\mu_{\beta} g^\nu_{\alpha} \right) F_{\mu\nu} \psi^\beta = -2i\mu m F_{\beta\alpha} \psi^\beta.$$  

The factor of $m$ is introduced so that the magnetic moment $\mu$ has the usual dimensions $[\mu] = -1$.

As noted above, while the spin operator $\xi^\mu$ commutes with the $\beta$ matrices for unequal indices, this is not true when the indices are equal. Consequently $\xi^\mu$ cannot commute with the transformation matrices $U^\mu$ (and therefore $U^{\mu\nu} = U^\mu U^\nu$), because $U^\mu$ contains all of the $\beta$ matrices at least once. Therefore we cannot simply derive the equivalent free Proca equation with a spin dependent phase.

However in the case that the fields are projected onto specific spin states, the action of the pseudo-spin operator $\xi_3$ on the Kemmer field $\phi$ yields the same eigenvalue $s_3$ as the spin operator $\hat{S}_3$ acting on the Proca fields $\psi^\mu$ and $G^{\mu\nu}$ derived from that Kemmer spinor using the relations given below. Therefore the magnitude/sign of the phase acquired in the Kemmer formalism is the same as that in the Proca formalism. Then the c-number phase $e^{i\lambda s_3 \phi}$ which modifies the Kemmer spinor does, as noted above, apply to both the Proca vector and the field tensor, and we can then generalise to the operator phase $e^{i\lambda \hat{S}_3}$ without a penalty for inexactness, under the standard conditions for Aharonov-Casher effect.

Speaking in general terms, the Kemmer equation can be thought of as an operator on the Kemmer wave function

$$O_K[A] \phi_K = 0,$$

and the transformation operator $T$ is defined such that the ten independent Proca fields $\psi_P = T \phi_K$. Then for a spin dependent phase

$$Te^{i\lambda \Sigma_3} \phi_{K_{\text{free}}} = Te^{i\lambda s_3} \phi_{K_{\text{free}}} = e^{i\lambda s_3} \psi_{P_{\text{free}}} = e^{i\lambda \hat{S}_3} \psi_{P_{\text{free}}}.$$  \hspace{1cm} (28)
In order to show this we choose a specific representation for the 10 component Kemmer spinor $\phi = (\phi_1, \phi_2, \ldots, \phi_10)^T$, and the related $\beta$-matrices. Our choice of the spinor components in terms of the Proca 4-vector $\psi^\mu$ and the Proca field strength $G^{\mu\nu}$ is exactly that given by Greiner [10], equation (15.43). Then the Proca equations can be written in the Kemmer form as

$$(i\beta_\mu \partial^\mu - m) \phi = 0$$

where the $10 \times 10$ matrices are:

$$\beta^0 = \begin{pmatrix} 0 & 0 & I & \bar{O}^\dagger \\ 0 & 0 & 0 & \bar{O}^\dagger \\ I & 0 & 0 & \bar{O}^\dagger \\ \bar{O} & \bar{O} & \bar{O} & 0 \end{pmatrix}, \quad \beta^k = \begin{pmatrix} 0 & 0 & 0 & -iK^{k\dagger} \\ 0 & 0 & S^k & \bar{O}^\dagger \\ 0 & -S^k & 0 & \bar{O}^\dagger \\ -iK^k & \bar{O} & \bar{O} & 0 \end{pmatrix}$$

(29)

where the elements are

$$\bar{O} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad I = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

$$S^1 = i \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad S^2 = i \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad S^3 = i \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$K^1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad K^2 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad K^3 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

(30)

It should be remarked that these $\beta$ matrices differ from those given by Greiner [10].

The spin operator for the Proca vector is given by:

$$S_3 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -i & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$  

(31)

Then from this, for $s_3 \neq 0$, $(s_3)^2 = 1$, we deduce $\psi^1 = -i s_3 \psi^2$, $\psi^0 = \psi^3 = 0$. The tensor components dependent on these are $G^{01} = i s_3 G^{01}$, $G^{23} = -i s_3 G^{23}$, and $G^{12} = -i s_3 \partial_\mu \psi^\mu = 0$. The condition on the polarization 4-vector that $s^\mu p_\mu = 0$, requires, for a spin orientation in the 3-direction, $\bar{\partial}^3 \psi^\mu = 0$. This with the condition that $\psi^3 = 0$, gives $G^{23} = 0$. As $S_3$ commutes with momentum operators we can express all these relations in the
Relativistic Aharonov-Casher Phase in Spin One

eigenfunction:
\[
\begin{pmatrix}
G_{01}^0 \\
is_3 G_{01}^0 \\
0 \\
G_{23}^0 \\
is_3 G_{23}^0 \\
0 \\
\psi^1 \\
is_3 \psi^1 \\
0 \\
0
\end{pmatrix}
\]  \[=\]
\[
\begin{pmatrix}
G_{01}^0 \\
is_3 G_{01}^0 \\
0 \\
G_{23}^0 \\
is_3 G_{23}^0 \\
0 \\
\psi^1 \\
is_3 \psi^1 \\
0 \\
0
\end{pmatrix}
\]

with the \(10 \times 10\) spin matrix \(\tilde{S}_3\),

\[
\tilde{S}_3 = \begin{pmatrix}
S_3 & 0 & 0 & \bar{O}^\dagger \\
0 & S_3 & 0 & \bar{O}^\dagger \\
0 & 0 & S_3 & \bar{O}^\dagger \\
0 & \bar{O} & \bar{O} & 0
\end{pmatrix}
\]  \[=\] (32)

In the Kemmer theory the spin operators are \(\Sigma_i = i \varepsilon_{ijk} [\beta_j, \beta_k]\). The \(\Sigma_3\) matrix is easily confirmed to be \(S_3\), i.e. the spin matrices from the two theories are identical. What, then, of the pseudo-spin operator \(\xi_3\)? Explicitly \(\xi_3 = i (\beta^0 \beta^1 \beta^2 + \beta^1 \beta^2 \beta^0 + \beta^2 \beta^0 \beta^1)\). So this matrix is

\[
\xi_3 = \begin{pmatrix}
0 & 0 & S_3 & \bar{O}^\dagger \\
0 & 0 & 0 & -iK^{3\dagger} \\
S_3 & 0 & 0 & \bar{O}^\dagger \\
\bar{O} & iK & \bar{O} & 0
\end{pmatrix}
\]  \[=\] (33)

which does not look like \(\Sigma_3\). However the operator is evaluated as (see Refs. [10, 11])

\[
\beta^0 \xi_3 = \xi_3 \beta^0 = \begin{pmatrix}
S_3 & 0 & 0 & \bar{O}^\dagger \\
0 & 0 & 0 & \bar{O}^\dagger \\
0 & 0 & S_3 & \bar{O}^\dagger \\
\bar{O} & \bar{O} & \bar{O} & 0
\end{pmatrix}
\]  \[=\] (34)

which is almost \(\Sigma_3\). The absent element operates (in the Proca case) on the components proportional to \(G_{23}^0\), which vanish as we saw. The action of \(\Sigma_3\) or \(\tilde{S}_3\) on the appropriate column is then equivalent to that \(\xi_3 \beta^0 \phi\).

This then demonstrates that the individual spin eigenstates of the two representations are transformed into one another. That means that the spin operator in the phase may be temporally replaced with its eigenvalue before performing the transformation between representations and then replaced with its counterpart. In this way the second element of the task of manifesting the transference of the AC phase from the Kemmer theory to the Proca formalism can be realized. A spin one object acquires the same phase in either theory when an equivalent magnetic moment interaction term is used. The problem of deriving the AC phase in the Proca formalism directly is the subject of the next section.
2.3. Calculation of AC Phase in Proca Theory

The Aharonov-Casher phase can be derived for the Proca vector using this phase technique, albeit with the conditions discovered earlier. Again we propose to identify the solution of the Proca equation with the anomalous magnetic moment interaction with a phase modified free Proca field. It was seen in §2.2 that the transformation of the Kemmer spinor showed that both the Proca vector and the Proca field were modified by the same phase (in spite of the fact that one is the derivative of the other): 

\[ \psi'_{\nu} = \exp \left( i \hat{S}_3 \int \vec{A}' \cdot d\vec{r} \right) \psi_{\nu}, \]

and 

\[ G'^{\mu \nu} = \exp \left( i \hat{S}_3 \int \vec{A}' \cdot d\vec{r} \right) G^{\mu \nu}. \]

Then the vector \( \psi'_{\nu} \) satisfies both

\[ \partial_{\mu} G^{\mu \nu} - 2i \mu m F_{\mu}^{\nu} \psi_{\mu} + m^2 \psi_{\nu} = 0, \]  \( (35) \)

with its subsidiary conditions, and

\[ \partial_{\mu} G'^{\mu \nu} + m^2 \psi'^{\nu} = 0, \]  \( (36) \)

also with its subsidiary conditions.

At this stage it is convenient to define the vector \( F'_{\nu} \) as the vector term of the magnetic moment interaction

\[ F'_{\nu} = F_{\mu}^{\nu} \psi_{\mu} = \begin{pmatrix} -E_1 \psi^1 - E_2 \psi^2 - E_3 \psi^3 \\ -E_1 \psi^0 - B_3 \psi^2 + B_2 \psi^3 \\ -E_2 \psi^0 + B_3 \psi^1 - B_1 \psi^3 \\ -E_3 \psi^0 - B_2 \psi^1 + B_1 \psi^2 \end{pmatrix}. \]

Then for spin projection \( \pm 1 \) eigenstates with \( B_k = E_3 = 0 \) the interaction term \(-2i \mu m F'_{\nu}\) becomes

\[ -2i \mu m F'^{0} = 2i \mu m \left( E_1 \psi^1 + E_2 \psi^2 \right) \]  \( (37) \)

This is the expression to be derived from equation \( (36) \). An immediate difficulty in this task is that this equation is inherently a second order equation. The action of the derivative on the path-dependent phase leaves a remnant term containing the field tensor, which is the first derivative of the Proca vector. This derivative can be eliminated using a relation derived now from the subsidiary equations.

By contracting \( \partial_\nu \) with eqs. \( (35) \) and \( (36) \) respectively gives

\[ m \partial_\nu \psi'_{\nu} = 2i \mu \partial_\nu F'_{\nu}, \]  \( (38) \)

\[ 0 = e^{is_3 \int \vec{A}' \cdot d\vec{r}} \left\{ is_3 \left( \partial_\nu A'_\mu \right) G^{\mu \nu} + m^2 \partial_\nu \psi'_{\nu} + is_3 m^2 A'_\nu \psi'_{\nu} \right\}. \]  \( (39) \)

So if the vector \( \psi'^{\mu} \) is to be a simultaneous solution of both equation \( (35) \) and \( (36) \) then it also satisfies the subsidiary conditions

\[ \partial_\nu \psi'^{\nu} = 2i \frac{\mu}{m} \partial_\nu F'_{\nu} = -is_3 \frac{s_3}{m^2} \left\{ \left( \partial_\nu A'_\mu \right) G^{\mu \nu} + m^2 A'_\nu \psi'_{\nu} \right\}. \]  \( (40) \)

Now if the fields \( A'_\mu \) satisfy the conditions \( A'_0 = \partial_0 A'_\mu = 0 \), then the first term of the second condition vanishes, and we have the useful relation

\[ 2i \mu \partial_\nu F'_{\nu} = -is_3 mA'_\nu \psi'_{\nu}. \]  \( (41) \)
Now the expansion of equation (36) as seen above leaves us attempting to make the remaining term $i s_3 A_\mu' G^{\mu\nu}$ look the part of the anomalous magnetic moment interaction (37). At this point it is assumed that the phase fields $A'_k$ are the same as those of §2.1. It is also assumed that $\psi^\mu$ is a spin eigenstate with $(s_3)^2 = 1$, so that $\psi^1 = -is_3 \psi^2$, etc.. Then, by substitution of the electric and Proca field identities:

$$is_3 A'_\mu G^{\mu\nu} = 2\mu m \partial^\mu F^0.$$  

(42)

We can take advantage of the fact that $F^i = 0$, to replace $\partial^i F^0$ with $\partial_\mu F^\mu$, and then introduce the identity (41). This gives $2\mu m \partial^0 F^0 = 2\mu m \partial_\mu F^\mu = -s_3 m A'_\mu \psi^\mu$. Now the last term gives us (repeating the substitution of the electric and Proca field identities),

$$s_3 m \left(A'^1 \psi^1 + A'^2 \psi^2 \right) = 2i\mu \left[E_1 \psi^1 + E_2 \psi^2 \right]$$

(43)

as the zeroth element of our vector. This is the interaction term (37) which was sought. Naturally the integral of the path-dependent phase $\hat{S}_3 \oint \vec{A}' d\vec{r}'$ equals the same phase as the Kemmer calculation, as that is how we have chose the field relations.

Hence the AC phase can be successfully calculated by the gauge method in the tensor formalism, although with the assistance of the relations first derived from the spinor theory, and is seen to be consistent between the two spin one theories.

3. Remarks

The topological nature of the Aharonov-Casher effect is delicate and its appreciation requires a subtle understanding. These derivations of the topological phase from spin 1/2 and spin one relativistic wave equations illuminate some of the difficulties at the intersection of quantum mechanics and classical electromagnetic theory, and those associated specifically with the AC effect.

Foremost are the explicit constraints on the geometrical alignment between the electric field, the particle momentum and the spin quantization axis. That these constraints are obscured in the non-relativistic derivation of the AC effect is evident by their protracted revelation in the literature. In contrast they evolve out of the relativistic derivation in an obvious manner because of the need to reduce the number of spinor components from which can contribute to a geometric, scalar phase. The implications of such strict limitations on the interpretation of experiments which have sought to measure the Aharonov-Casher phase are self-evident.

Furthermore these studies indicate the extraordinary care which must be taken in applying semi-classical models to spin or the magnetic moment, or even the particle’s trajectory. The natural determination of a spinor’s properties out of the transformation properties of the $SL(2,C)$ group contrasts with the difficult interpolation of spinor behaviour in a non-relativistic framework. In the case of the AC effect, satisfaction of the geometrical constraints for a geometric phase is dependent on the choice of interpretation of the classical vector which substitutes for the spin dynamics. In many cases a phase can still be derived from classical origins which is mistakenly thought to be the geometric phase. Similarly the problem of the ‘hidden momentum’ of a magnetic dipole is clarified
by comparison with the non-relativistic equations derived from the complete relativistic wave equations.

Finally the existence of the AC phase for all the spin components of a spin 1 particle, together with the geometrical constraints, mark out the differences between the Aharonov-Bohm and Aharonov-Casher effects, and underscore the limitations of ‘equivalence’ methods of studying the AC effect using the former. Equivalence methods can only map two possible spin states onto the charge states of the Aharonov-Bohm effect, and consequently omit part of the richness of the AC effect.

4. Conclusion

The Aharonov-Casher phase has been successfully calculated for spin one relativistic particles in both relativistic theories with equivalent electromagnetic interactions. In the Kemmer theory, the definition of a pseudo-vector spin operator $\xi_\mu$ has permitted the imitation of the gauge technique used by He and McKellar in spin $1/2$ to find the AC phase, subject to the conditions familiar from spin $1/2$. In order to demonstrate that these results hold in the more familiar Proca wave theory, the two equations, one with the interaction, the other with the modified phase, have been shown to transform into their equivalents using the established projection operators. Finally, with the conditions derived from the previous studies, the Aharonov-Casher phase has been calculated directly in the Proca formalism itself. The coherence of these results demonstrates the validity of the spin dependence in the AC effect for higher spins.

Acknowledgments

The authors wish to thank Xiao-Gang He for useful discussions. One author (JAS) would also like to acknowledge the support of an Australian Postgraduate Award.
