ABSTRACT: To explore the structural transformation of cyclopentadienyl ruthenium (CpRu) complexes in response to external stimuli, the reaction of [RuCp(MeCN)3][X] (X = PF6, (FSO2)2N [= FSA]) and tris(alkylthio)benzenes (1,3,5-C6H3(SR)3; L1: R = Pr; L2: R = Me) was investigated, and the crystal structures and thermal properties of the products were examined. The reaction produced the sandwich complexes [RuCpLn][X] or dinuclear complexes [Ru2Cp2(μ-L)n][CH3CN]m[X]2 (X = PF6, FSA) depending on the reaction conditions. The sandwich complex [RuCpL][FSA] was an ionic liquid. The solids of dinuclear complexes transformed into the thermodynamically stable sandwich complexes upon heating accompanied by acetonitrile loss. This change resulted in a transformation from crystal to ionic liquid for complexes with the FSA anion. UV irradiation of the sandwich complex [RuCpL][PF6] in methanol produced the dinuclear complex [Ru2Cp2(μ-L)2L][PF6]2. The complex transformed into the sandwich complex upon heating.

INTRODUCTION

Many cyclopentadienyl ruthenium (CpRu) complexes have been synthesized to date because of the interest in their chemical reactivities and catalytic activities.1−15 They are also used for the construction of various supramolecular assemblies.16−18 A versatile precursor for their production is the triacetonitrile complex [RuCp(MeCN)3]+,9−13 which produces cationic sandwich-type Ru complexes upon reaction with arene ligands.13−15

Ionic liquids are salts with melting points below 100 °C,23,24 and we have synthesized a variety of organometallic ionic liquids containing cationic sandwich complexes.19−22 In particular, ionic liquids with the formula [RuCp(arene)][X] (X = fluorinated anion) have been prepared using the reaction of [RuCp(MeCN)3]+ with arene ligands.25−28 As part of this investigation, we previously found that the reaction with ortho-substituted benzenes afforded either sandwich-type or chelate complexes depending on the reaction conditions (Figure 1), and their interconversion in solution was possible upon application of light and heat.29 Based on this mechanism, organometallic ionic liquids that transform into amorphous coordination polymers upon photo-irradiation were designed.30,31

In this study, to further explore the structural transformations of CpRu complexes via external stimuli, the reaction of the triacetonitrile complex with meta-substituted ligands was performed because they cannot form chelate complexes unlike the ortho-substituted benzenes. The reaction with 1,3,5-C6H3(SR)3 ligands (L1: R = Pr; L2: R = Me) produced sandwich-type or dinuclear complexes depending on the reaction condition (Figure 2). The hexafluorophosphate (PF6−) and bis(fluorosulfonyl) amide ((FSO2)2N−; FSA) anions were used as counter anions. The FSA anion is often

Figure 1. Reaction of [RuCp(MeCN)3]+ with 1,2-disubstituted benzene ligands (L). Transformation between the products occurs in acetonitrile by application of light and heat (E, E′ = SMe, NMe2).

Figure 2. Reaction of [RuCp(MeCN)3]+ with 1,3,5-C6H3(SR)3 ligands (L1: R = Pr; L2: R = Me) produced sandwich-type or dinuclear complexes depending on the reaction condition. The hexafluorophosphate (PF6−) and bis(fluorosulfonyl) amide ((FSO2)2N−; FSA) anions were used as counter anions. The FSA anion is often
used for the preparation of ionic liquids. The thermal properties of the products were investigated using differential scanning calorimetry (DSC), along with crystal structure determination. Furthermore, the thermal reactivity of the dinuclear complexes and the photochemical reactivity of the sandwich-type complexes were investigated.

### RESULTS AND DISCUSSION

#### Preparation and Thermal Properties of the Sandwich-Type Complexes.

A solution of [RuCp(MeCN)₃][PF₆] and L₁ or L₂ in 1,2-dichloroethane was heated at 90 °C for 16 h to produce the sandwich-type complexes [1a][PF₆] and [1b][PF₆] in 83 and 76% yields, respectively (Figure 2, top), as pale yellow crystals. In addition, [1a][FSA] was synthesized using the same procedure from [RuCp(MeCN)₃][FSA] in 75% yield. The complex was obtained as a pale yellow liquid, which solidified upon application of physical agitation at low temperature (−16 °C).

The thermal properties of the prepared complexes were investigated via DSC, and the obtained data are summarized in Table 1 and Figure 3. The melting points of [1a][PF₆] and [1b][PF₆] were 99.5 and 213.7 °C, respectively, and they crystallized upon cooling from the melt (Figure 3a). The melting point of [1a][FSA] was 42.7 °C, and this salt can be regarded as an ionic liquid. Once melted, this salt maintained the liquid state at room temperature, exhibiting a glass transition at −57 °C upon further cooling (Figure 3b). The ratio of the glass transition temperature to the melting point (T<sub>g</sub>/T<sub>m</sub>) was 0.68, in agreement with the empirical relationship (T<sub>g</sub>/T<sub>m</sub> ≈ 2/3). This complex exhibited a phase transition at −53.5 °C (ΔH = 1.3 kJ mol⁻¹) in the solid state.

#### Crystal Structures of the Sandwich-Type Complexes.

The crystal structures of [1a][PF₆] and [1b][PF₆] were determined at 90 K, crystallizing in space groups P<sub>2</sub>₁<sub>2</sub>₁<sub>2</sub> and P<sub>2</sub>₁/c, respectively. The packing diagrams are provided in Figure S1 (Supporting Information), and the structures of the cations are shown in Figure 4. One of the four crystallo-
graphically independent cations is shown for [1a][PF$_6$], while the other cations are provided in Figure S2 (Supporting Information) and exhibit different substituent conformations. The Ru–C$_{\text{centroid}}$ and Ru–Arene$_{\text{centroid}}$ distances in these cations are 1.82 and 1.71 Å, respectively, which are usual values for CpRu complexes. The C–S–C angles of [1a][PF$_6$] and [1b][PF$_6$] were 101.5°–101.1° and 102.8°–103.3°, respectively. In both crystals, the cations exhibited intermolecular π–π interactions between the arene rings, forming a dimeric structure with centroid–centroid distances of 3.43 ([(1a)[PF$_6$]]) and 3.37 Å ([(1b)[PF$_6$]]), respectively.

**Preparation and Thermal Properties of the Dinuclear Complexes.** The reaction of [RuCp(MeCN)$_3$][PF$_6$] and the ligands in acetone at room temperature produced orange crystals of [RuCp(MeCN)$_3$][PF$_6$]$_2$ and [RuCp(MeCN)$_3$][FSA]$_2$ in 28 and 37% yields, respectively. Similarly, the reaction of [RuCp(MeCN)$_3$][FSA] and L$^1$ under the same conditions produced orange crystals of [2a$^*$][FSA]$_2$ in 22% yield.

Thermogravimetric (TG) analysis showed that the acetonitrile ligands in the complexes are released upon heating. The TG curves of [2a][PF$_6$]$_2$ and [2b][PF$_6$]$_2$ measured at 10 °C min$^{-1}$ are shown in Figure 5. Weight losses of approximately 6 wt% at 140–160 °C (Figure 5a) and 10 wt% at 158–180 °C (Figure 5b) corresponded to the loss of acetonitrile (calculated values: 6.3 and 7.2 wt%, respectively). At higher temperatures (approximately 200–350 °C), both complexes showed a gradual weight loss of approximately 60 wt%, corresponding to the arene ligand loss (calculated values: 50.9 and 61.5 wt%, respectively).

[2a][PF$_6$]$_2$ exhibited melting and acetonitrile loss simultaneously, which was observed as an endothermic peak at approximately 152 °C (onset: 141 °C) in the differential thermal analysis (DTA) curve (Figure 5a), whereas [2b][PF$_6$]$_2$ melted at a higher temperature than the acetonitrile loss, exhibiting two peaks at approximately 168 and 202 °C (onset) in the DTA curve (Figure 5b). Their thermal properties were also investigated using DSC (see below), which revealed that the loss of acetonitrile was accompanied by a structural transformation to the sandwich complexes.

**Crystal Structures of the Dinuclear Complexes.** The crystal structures of [2a][PF$_6$]$_2$ and [2b][PF$_6$]$_2$ were determined at 90 K, and the dinuclear cationic complex structures are shown in Figure 6. The two Ru ions in each cation are bridged by two arene ligands, where each Ru ion is coordinated with an acetonitrile and the two sulfur atoms of the arene ligands. Therefore, one of the three sulfur atoms in each arene ligand remained uncoordinated. In [2a][PF$_6$]$_2$, three of the six propyl substituents exhibited twofold disorder with occupancies of 0.76:0.24. One Cp ring exhibited rotational disorder over two sites with an occupancy of 0.58:0.42. The coordination bond lengths in [2a][PF$_6$]$_2$, (Ru–S = 2.35–2.39 Å, Ru–N = 2.06 Å) and [2b][PF$_6$]$_2$, (Ru–S = 2.37 Å, Ru–N = 2.06 Å) were almost identical. However, the coordination angles of S–Ru–N (84.1°–93.4°) in [2a][PF$_6$]$_2$; 92.9° in [2b][PF$_6$]$_2$ and S–Ru–S (93.4 and 94.9° in [2a][PF$_6$]$_2$; 98.7° in [2b][PF$_6$]$_2$) differed slightly probably because of the packing effect. The two arene rings in the cation of [2a][PF$_6$]$_2$ exhibited a 11.6° dihedral angle, whereas those in [2b][PF$_6$]$_2$ were oriented in a parallel manner because the cation is located on the inversion center. The centroid–centroid distances between the two arene rings in these complexes were 3.65 and 3.53 Å, respectively, and were likely stabilized by intramolecular π–π interactions. The dinuclear structure resembles the structural motif of the previously reported Ag$^+$ coordination polymer [Ag$_2$(bsb)$_2$(ClO$_4$)$_2$]$_n$ [bsb = 1,3,5-tris(benzylsulfonyl)benzene].

![Figure 6. Molecular structures of the cations in (a) [2a][PF$_6$]$_2$ and (b) [2b][PF$_6$]$_2$](https://dx.doi.org/10.1021/acsomega.9b04272)
The crystal structure of [2a′][FSA]₂ could not be determined, but it likely has a similar dinuclear structure. This complex contains only one acetonitrile ligand in the cation, in contrast to [2a][PF₆] and [2b][PF₆]; hence, a sulfide moiety of an adjacent unit in the crystal probably coordinates to the metal center instead of acetonitrile. This structure seems plausible considering the structure of [3a][PF₆]₂ (see below).

**Thermal Conversion from a Dinuclear to Sandwich-Type Complex.** The formation of the sandwich-type and dinuclear complexes by the reactions at 90 °C and room temperature, respectively, indicates that they are the thermodynamic and kinetic products, respectively. DFT calculations also indicated that the sandwich-type complex is thermodynamically more stable (Figure S3, Supporting Information). Based on this feature, we could observe a thermal transformation from the dinuclear complex to the sandwich-type complex.

The photographs taken upon heating the crystals of [2a][PF₆]₂ are shown in Figure 7a. Upon heating, the orange crystals melted at approximately 150 °C, affording an orange liquid [Figure 7a(ii)]. The liquid turned to a pale yellow liquid of [1a][PF₆] as a white solid [Figure 7c, top row, (i)]. The solid melted upon further heating to approximately 210 °C. On the other hand, upon heating single crystals, melting was observed at around 165 °C [Figure 7c, bottom row, (i)]. This was due to the presence of acetonitrile in the product. Consistently, when DSC measurements of [2b][PF₆]₂ was performed in a sealed pan (Figure 8b), melting occurred at 166.4 °C with structural transformation, yielding a large enthalpy change (ΔH = 93.7 kJ mol⁻¹). In the second cycle, melting was observed at around 200 °C because most of the acetonitrile has escaped during subsequent heating.

**Photochemical Reaction of the Sandwich-type Complex.** The sandwich complex [1a][PF₆] underwent a photochemical reaction in solution (365 nm), yielding a dinuclear complex (Figure 2, upper right). [1b][PF₆] was insoluble in methanol and unsuitable for photoreaction investigation. UV irradiation of [1a][PF₆] in methanol for 3 h produced orange crystals of [Ru₂Cp₂(μ-L₁)L₁][PF₆]₂ ([3a][PF₆]₂) in 28% yield. The structure of the cation was determined by X-ray crystallography at 90 K and is shown in Figure 9 (space group
P-1). The cation exhibited a dinuclear structure similar to that of [2a][PF₆]₆, but with four arene ligands, two of which were coordinated to the Ru ions instead of acetonitrile. The cation adopted a centrosymmetric structure, and the two arene rings bridging the Ru ions were arranged in parallel. The centroid−centroid and interplane distances between the two were 3.80 and 3.21 Å, respectively. The average Ru−S bond lengths and S−Ru−S angles were 2.38 Å and 84.6°−93.3°, respectively. Four of the six crystallographically independent propythio substituents exhibited twofold disorder, with occupancy ratios of 0.50:0.50−0.81:0.19.

Heating the [3a][PF₆]₂ solid at 170 °C for 5 min quantitatively afforded a mixture of [1a][PF₆] and L¹. Therefore, this dinuclear cation was thermally transformed to a sandwich complex, similar to the other dinuclear complexes.

**CONCLUSIONS**

The reaction of the triacetonitrile CpRu complex [RuCp-(MeCN)₃]⁺ with 1,3,5-tris(alkylthio)benzenes produced either sandwich-type complexes or dinuclear complexes depending on reaction conditions. Dinuclear complex formation from the meta-substituted ligands is a striking contrast to the formation of mononuclear chelate complexes from the ortho-substituted ligands. The dinuclear complexes exhibited a novel structural type and are interesting from a supramolecular perspective. Furthermore, the dinuclear complexes transformed to thermodynamically stable sandwich complexes upon heating concomitant with the loss of acetonitrile. The sandwich complex photochemically produced a dinuclear complex with the same procedure as [1a][PF₆] using [RuCp(MeCN)₃][PF₆] (51.2 mg, 0.12 mmol) and 1-bromopropane (71 mg, 0.57 mmol) were added to a DMSO (1.5 mL) solution of 1,3,5-benzenetetrithiol (20 mg, 0.12 mmol) and stirred at room temperature for 10 min under a nitrogen atmosphere. The reaction mixture was subsequently heated to 50 °C and stirred for 1 d. Water (7.5 mL) was added to the mixture, and the solution was extracted with diethyl ether. The organic layer was washed with water and a saturated saline solution. The solution was dried over anhydrous MgSO₄, and the solvent was then evaporated under reduced pressure. The resultant pale yellow liquid was dried under vacuum for 5 h at room temperature (28 mg, 81%). ¹H NMR (400 MHz, CDCl₃): δ 1.03 (t, 9H, CH₂₋J = 14.7 Hz), 1.67 (sext, 6H, CHₓ₋J = 7.59 Hz), 2.88 (t, 6H, CH₂₋J = 14.7 Hz), 7.02 (s, 3H, C₆H₃). ESI-MS (m/z): [M + H]⁺ calculd for C₁₅H₂₅S₃, 301.1118; found, 301.1109.

**Synthesis of the Sandwich-Type Complexes.** [RuCpL¹][PF₆] (1b)[PF₆]). L¹ (77 mg, 0.26 mmol) was added to a dehydrated 1,2-dichloroethane solution (2 mL) of [RuCp(MeCN)₃][PF₆] (56 mg, 0.11 mmol), and the resulting solution was refluxed for 20 h under a nitrogen atmosphere. The resulting solution was evaporated under reduced pressure, and the residue was dissolved in a small amount of dichloromethane before being subjected to column chromatography (alumina, eluent: diethyl ether and then acetonitrile). The fraction containing the desired salt was collected and evaporated. The residue was dissolved in a small amount of acetone, to which excess diethyl ether was added to precipitate the product as a white powder (65 mg, 83%). Pale yellow crystals were obtained upon recrystallization from acetone−diethyl ether at −40 °C (36 mg, 46%). ¹H NMR (400 MHz, CDCl₃): δ 1.07 (t, 9H, CH₂₋J = 7.4 Hz), 1.73 (sext, 6H, CHₓ₋J = 7.4 Hz), 5.30 (s, 5H, C₆H₃), 6.53 (s, 3H, C₆H₃). FT-IR (ATR, cm⁻¹): 641, 902, 2040, 2912, 2362, 1379, 2873, 2934, 2965, 3117. Anal. Calcd for C₁₅H₁₉F₆P₃Ru:C: 39.26; H, 4.84; N, 0.09. Found: C, 39.26; H, 4.84; N, 0.09.

**Experimental Section.**

General. ¹H NMR spectra were recorded using a Bruker AVANCE 400 spectrometer, and IR spectra were recorded using a Thermo Nicolet Avatar 360 FT-IR spectrometer (ATR method). Elemental analyses were performed using a PerkinElmer 2400II elemental analyzer. DSC measurements were performed using a TA instruments Q100 differential scanning calorimeter at a 10 °C min⁻¹ scan rate. TG analyses were performed under a nitrogen atmosphere at a 10 °C min⁻¹ heating rate using a Rigaku TG8120 TG analyzer. DFT calculations were performed at the oB97-D/LanL2DZ level using Spartan’18 software. Single-crystal X-ray diffraction data were collected using a Bruker APEX II Ultra diffractometer with Mo Kα radiation at 90 K. The structures were solved using SHELXS and the crystallographic parameters are provided in Tables S1 and S2 (Supporting Information).
A solution of [RuCl2(μ-L1)L2][PF6]2 (15 mg, 0.032 mmol) and [RuCl2(MeCN)3][PF6] (18.5 mg, 0.056 mmol) was added to an acetone (0.5 mL) in a test tube. Diethyl ether (10 mL) was added to the dark at room temperature for 2 days (16.1 mg, 29%). The product was obtained free of charge via www.ccdc.cam.ac.uk/data_request/cif.
