Abstract. We calculate tensor bispectrum in a theory of massive tensor gravitons which predicts blue-tilted and largely amplified primordial gravitational waves. We find that a new 3-point interaction can produce a larger tensor bispectrum than the conventional one from general relativity. The bispectrum peaks at the squeezed configuration and its slope towards the squeezed limit is determined by the graviton mass. This squeezed tensor bispectrum may be observed as the quadrupolar modulation of the tensor power spectrum by interferometers.

Keywords: primordial gravitational waves (theory), modified gravity, inflation

ArXiv ePrint: 1909.07563
1 Introduction

Cosmic inflation is widely believed to be the most plausible explanation for the origin of primordial perturbations in our Universe, while it is still nontrivial to embed inflation into more fundamental theories (see [1], for a review). Inflation predicts the existence of primordial gravitational waves (GWs), whose power spectrum amplitude depends on the value of the Hubble expansion rate during inflation (see [2], for a review). In order to detect or put constraints on the primordial GWs, there are future/ongoing experiments of Cosmic Microwave Background (CMB) B-mode polarization like Lite BIRD [3] as well as interferometers such as LISA [4], Advanced-LIGO (A-LIGO) [5] and DECIGO [6, 7]. In most models of inflation, the power spectrum of primordial GWs is almost scale invariant, with a slightly red tilt, where the most promising way to detect the primordial GWs is through CMB B-mode polarization. Nevertheless, it should be stressed that even if inflation occurred, there are scenarios where the amplitude of primordial GWs can be amplified at scales much smaller than CMB’s (see for reviews, [8, 9]). These scenarios are observationally interesting, since they open up the possibility that the primordial GWs can be detected by interferometer experiments, even if their signal is not observed at the CMB scale.\(^1\)

Among the various scenarios showing interesting features for the primordial GWs at small scales, massive gravity (see [11], for a review) attracts conspicuous attention and has been applied to the study on the primordial GWs [12–15]. In this context, recently we have proposed a new scenario predicting blue-tilted and largely amplified primordial GWs [16]. This prediction is based on the two assumptions, where the first one is that the mass of tensor graviton is comparable to the Hubble expansion rate during the inflation and the second one is that the mass diminishes to a small value at a certain time during radiation dominated era. Owing to the first assumption, the power spectrum of primordial GWs is

\(^1\)However, recently a new method was proposed to constrain the amplitude of the primordial GWs from the CMB data at Mpc scale, see [10].
blue at the end of inflation. From the second one, after inflation until the mass diminishes to a small value, gravitons are diluted as non-relativistic matter and hence their amplitude can be substantially amplified compared to the conventional massless gravitons which decay as radiation. In conventional massive gravity theories including the one proposed by de Rham-Gabadadze-Tolley (dRGT) [17, 18], it is well known that the tensor graviton mass that is positive and comparable to the Hubble expansion rate is prohibited around de Sitter background by the so-called Higuchi bound [19]. Contrary to this, however, there are viable theories in which the graviton mass in such region does not introduce instabilities, like the minimal theory of massive gravity (MTMG) [20, 21]. In MTMG, there are only two physical degrees of freedom propagating as in general relativity in the gravity sector and the would be ghost mode is removed from the construction, where the assumption of the Lorentz-invariance is relaxed (see [22–27] for works considering interesting phenomenology based on Lorentz-violating massive gravity).

The scenario of [16] has similarity with the one of [28] based on a generalization of solid inflation [29, 30] dubbed supersolid inflation [31] (see [32–34] for related works). Supersolid inflation is a scenario that simultaneously breaks time reparametrization and spatial diffeomorphisms during inflation based on the Effective Field Theory (EFT) of inflation [35]. Such a symmetry breaking pattern is accompanied by the appearance of the tensor graviton mass that can be comparable to the Hubble expansion rate during inflation without introducing ghost instability. Therefore, the fact that the graviton mass comparable to the Hubble expansion rate during inflation makes the primordial GWs blue-tilted holds in both scenarios. The mechanism to enhance the primordial GWs so that it is detectable by interferometers, however, is different. Since supersolid inflation is based on EFT of inflation described by four scalar fields having time- and space-dependent vevs which break reparametrization symmetries of the background, at the end of inflation, these fields are regarded to arrange themselves so that the space-reparameterization symmetry is recovered. Therefore, in the scenario of [28], the mass of tensor graviton becomes zero at the end of inflation, where the enhancement mechanism in the scenario of [16] is not applicable.

Given the situation that there are several scenarios that predict primordial GWs detectable at interferometer scales, it is important to think about how to distinguish them. In this respect, the statistical property of primordial GWs is a very helpful tool, as in the case of primordial curvature perturbations. For example, the primordial GWs from vacuum fluctuations of the metric are almost Gaussian [36, 37]. Furthermore, stochastic gravitational wave backgrounds due to a combination of a large number of uncorrelated astrophysical sources is Gaussian to a high degree, due to the central limit theorem. Therefore, in this paper, we calculate the bispectrum of primordial GWs, which is the lowest order statistics providing information on non-Gaussianity of tensor fluctuations, depending on not only the amplitude, but also the shape of the triangle composed of the three momentum vectors in the scenario of [16] (for other works discussing tensor non-Gaussianity, see [38–48]).

It seems that the simplest way to detect the primordial tensor bispectrum is the direct measurement of the bispectrum at interferometer scales [49]. However, it was shown that the bispectrum cannot be probed directly [50, 51]. This is caused by the fact that the tensor bispectrum at small scales is suppressed due to Shapiro time-delay effects associated with the propagation of tensor modes at sub-horizon scales in the presence of matter. On the other hand, for supersolid inflation, another method to prove the tensor bispectrum based on

\[2\] In the scenario of [28], it is possible to obtain the primordial GWs detectable by interferometers by considering small speed of sound for the tensor perturbations.
the quadrupolar modulation of the tensor power spectrum induced by the tensor bispectrum was proposed [28]. As mentioned above, since there is similarity between Lorentz-violating massive gravity and supersolid inflation, it is expected that the quadrupolar modulation of the tensor power spectrum is also induced in the Lorentz-violating massive gravity. Therefore, we calculate the quadrupolar modulation of the tensor power spectrum induced by the tensor bispectrum and briefly discuss the detectability.4

The rest of this paper is organized as follows. In section 2, we briefly summarize the result on the tensor power spectrum in the scenario of [16]. Then, in section 3, we calculate the tensor bispectrum in the same scenario today based on the in-in formalism. In section 4, we calculate the quadrupolar modulation of the tensor power spectrum sourced by the tensor bispectrum and consider the detectability. Section 5 is devoted to conclusions and discussions.

2 Dynamics of massive graviton

Here, we briefly explain our setup which was developed in ref. [16]. Our quadratic action for the tensor graviton $h_{ij}(\tau, x)$ is given by

$$S_{(2)}^h = \frac{M_{Pl}^2}{8} \int d\tau d^3x \, a^2 \left[ h_{ij}' h_{ij}' - \partial_i h_{ij} \partial_j h_{ij} - a^2 \mu^2 h_{ij} h_{ij} \right], \quad (2.1)$$

where $M_{Pl}$ is the reduced Planck mass, $a(\tau)$ is the scale factor, $\mu(\tau)$ is the mass of the tensor graviton, $\tau$ is the conformal time and a prime denotes its derivative, i.e. $X' \equiv \partial_{\tau} X$. The tensor gravitons can be decomposed and quantized as

$$h_{ij}(\tau, x) = \frac{2}{a M_{Pl}} \sum_{\lambda=+,-} \int \frac{d^3k}{(2\pi)^3} e^{i k x} e^\lambda_{ij}(\hat{k}) a_k^\lambda + \text{h.c.}, \quad (2.2)$$

where $e^\lambda_{ij}(\hat{k})$ is the polarization tensor and $a_k^\lambda / \tilde{a}_k^\dagger$ are creation/annihilation operators satisfying the commutation relation, $[\tilde{a}_k^\lambda, a_p^{\dagger \sigma}] = (2\pi)^3 \delta^\lambda_\sigma \delta(k - p)$. Henceforth, we often suppress the polarization label $\lambda$ when it is not relevant.

To obtain the evolution of the mode function $v_k(\tau)$, we need to specify $a(\tau), \mu(\tau)$ and the initial condition for $v_k(\tau)$. For simplicity, we assume the de Sitter expansion $a \propto \tau^{-1}$ during inflation as well as instantaneous reheating followed by the radiation dominated era $a \propto \tau$, which gives

$$a(\tau) = \begin{cases} -1/(H_{\text{inf}} \tau) & (\tau < -\tau_r) \\ a_r \tau/\tau_r & (\tau > \tau_r) \end{cases}. \quad (2.3)$$

Here $H_{\text{inf}}$ is the Hubble expansion rate during inflation and $a_r$ is the scale factor at the reheating time $\tau_r = (a_r H_{\text{inf}})^{-1}$. Note that in this treatment the conformal time $\tau$ jumps

---

3The idea that the squeezed tensor bispectrum induces the quadrupolar modulation of the power spectrum of curvature perturbation was proposed earlier and has been investigated actively in the name of ‘tensor fossils’ [52–55].

4For the discussion on the detection of primordial GWs with pulsar timing arrays like SKA [56], see [57].

5The polarization tensor $e^\lambda_{ij}(\hat{k})$ generally satisfies the transverse-traceless condition $k_i e^\lambda_{ij}(\hat{k}) = e^\lambda_{ij}(\hat{k}) = 0$. Since we employ the circular polarization tensor, we also have the normalization conditions $e^\lambda_{ij}(\hat{k}) e^{\lambda'}_{ij}(\hat{k}) = \delta_{\lambda\lambda'}$ and the following properties $e^\pm_\lambda(\hat{k}) = e^\mp_\lambda(-\hat{k})$ for $\lambda = \pm$. 

4
from $-1/(aH_{\text{inf}})$ into $1/(aH_{\text{inf}})$ at reheating for $a$ and $da/d\tau$ to be continuous. We further assume a simple step-function behavior of the graviton mass,

$$
\mu(\tau) = \begin{cases} 
m & (\tau < \tau_m) 
0 & (\tau > \tau_m),
\end{cases}
$$

(2.4)

where $\tau_m$ is a certain time during radiation dominated era. Although we do not discuss its specific mechanism in this paper, this mass transition can be caused, for example, by a scalar field whose vacuum expectation value controls the graviton mass and whose excursion is triggered by the temperature of the universe.\footnote{Promoting the parameters in the graviton mass term to functions of a scalar field or scalar fields (but not of its or their derivatives), the constraint algebra of MTMG does not change and thus the number of local physical degrees of freedom in the gravity sector remains to be two.}

Finally, we set the initial condition for the mode function to be that for the Bunch-Davies vacuum during inflation,

$$
\lim_{k\tau \to -\infty} v_k(\tau) = \frac{1}{\sqrt{2k}} e^{-ik\tau}.
$$

(2.5)

Solving the equation of motion (EoM) based on the above setup, one can show that the mode function $v_k(\tau)$ during inflation is given by

$$
v_k(\tau < \tau_r) = \sqrt{-\frac{\pi \tau}{2}} H^{(1)}_\nu(-k\tau), \quad \nu \equiv \sqrt{\frac{9}{4} - \frac{m^2}{H_{\text{inf}}^2}}.
$$

(2.6)

where $H^{(1)}_\nu$ is the Hankel function of the first kind of order $\nu$. To discuss the mode function during inflation in more detail, it is useful to introduce a new dimensionless time variable $x \equiv -k\tau$. Well after the horizon exit, $x \ll 1$, the mode function has the asymptotic form

$$
\lim_{x \to 0} v_k(x) = \sqrt{\frac{\pi}{2k}} \left[ \frac{1}{\Gamma(1 + \nu)} \left( \frac{x}{2} \right)^{1+\nu} - i \frac{\Gamma(\nu)}{\pi} \left( \frac{x}{2} \right)^{1-\nu} \right], \quad (\tau < \tau_r),
$$

(2.7)

where $\Gamma(\nu)$ is the gamma function. Although the second term is always dominant in the magnitude, the first term which carries the real part of $v_k$ also plays an important role in the calculation of the tensor bispectrum, as we will see in the next section.

The ratio of the mode functions between the current massive case ($v_k^\text{massive}(\tau)$) and the usual massless case ($v_k^\text{massless}(\tau)$) is evaluated at the end of inflation as

$$
\Upsilon_k(\tau) \equiv \left| \frac{v_k^\text{massive}(\tau)}{v_k^\text{massless}(\tau)} \right| \Rightarrow \Upsilon_k(\tau_r) \simeq \frac{\Gamma(\nu)}{\Gamma(3/2)} \left| \frac{k\tau_r}{2} \right|^{\frac{3}{2} - \nu}.
$$

(2.8)

Since $|k\tau_r| \ll 1$ and $\nu < 3/2$ for the massive graviton on super-horizon scales, the mode function is suppressed compared to the conventional massless case. On the other hand, after inflation ends and the Hubble expansion rate $H$ decreases, the super-horizon graviton modes behave as non-relativistic matter with $m > H > k/a$. Then the mode function is relatively amplified, $\Upsilon_k \propto a^{1/2}$, compared to the massless graviton modes which behave as radiation. This amplification continues until the graviton mass vanishes at $\tau = \tau_m$. The ratio of the mode functions is then given by [16]

$$
\Upsilon_k(\tau \gg \tau_m) = \gamma_k \sqrt{\frac{\tau_m}{\tau_r}} \left| \frac{k\tau_r}{2} \right|^{\frac{3}{2} - \nu},
$$

(2.9)
where $\gamma_k$ has a rather lengthy expression obtained by solving the junction conditions, but it is $O(1)$ for $m/H_{\text{inf}} \sim 1$. As a result, the dimensionless power spectrum of the tensor modes is written as

$$P_h(k, \tau \gg \tau_m) = \tilde{\gamma}_k^2 |k\tau_r|^{3-2\nu} \frac{\tau_m}{\tau_r} P_{h}^{\text{massless}}(k, \tau),$$

with $\tilde{\gamma}_k \equiv \gamma_k \times 2^{\nu-3/2} \Gamma(\nu)/\Gamma(3/2)$. Here, $P_{h}^{\text{massless}}$ denotes the usual power spectrum of the massless tensor modes from inflation,

$$P_{h}^{\text{massless}}(k, \tau) = T_k^2(\tau) \frac{2H_{\text{inf}}^2}{\pi^2 M_{Pl}^2},$$

with the transfer function of the massless tensor modes,

$$T_k(\tau) \equiv \frac{h_{k \text{massless}}(\tau)}{h_{k \text{massless}}(\tau_r)} = \frac{a(\tau)}{a(\tau_r)} \frac{v_{k \text{massless}}(\tau)}{v_{k \text{massless}}(\tau_r)}.$$

If gravitons keep the mass for a while after inflation $\tau_m \gg \tau_r$, it overcomes the damping factor in eq. (2.8) and the gravitational waves can be substantially amplified for relevant modes with $|k\tau_r|^{3-2\nu}\tau_m/\tau_r \gg 1$. The tensor tilt is

$$n_T \equiv \frac{d \ln P_h(\tau_r)}{d \ln k} = 3 - 2\nu,$$

where the $O(\epsilon_H)$ slow-roll correction is ignored under the assumption $m/H_{\text{inf}} = O(1)$. Notice that the tilt of the power spectrum is blue, $n_T > 0$, because the mode function decays on super-horizon scales during inflation.

### 3 Tensor bispectrum

In this section, we calculate the tensor bispectrum. We consider the following interaction Hamiltonian at the third order for the tensor perturbation:

$$H_{\text{int}} = H_{\text{int}}^{(GR)} + H_{\text{int}}^{(mass)},$$

with

$$H_{\text{int}}^{(GR)} = -\frac{M_{Pl}^2 a^2}{4} \int d^3 x h_{ij} h_{kl} \left( \partial_j \partial_l h_{ik} - \partial_i \partial_j \frac{1}{2} h_{kl} \right),$$

$$H_{\text{int}}^{(mass)} = -g \frac{M_{Pl}^2}{4} a^4 \int d^3 x h_{ij} h_{jk} h_{ki},$$

where the coefficient $g(\tau)$ depends on time. $H_{\text{int}}^{(GR)}$ is found even in general relativity (GR) around de Sitter space. On the other hand, $H_{\text{int}}^{(mass)}$ is absent in GR and it arises from the same argument as the graviton mass term as discussed in appendix A. We assume $g$ is also constant during inflation in the same way as the graviton mass $\mu$ (see eq. (2.4)). It is worth mentioning that $H_{\text{int}}^{(mass)}$ also appears in supersolid inflation [28, 34], which suggests that the appearance of this interaction is a generic feature of the breaking of the space reparameterization symmetry.
The three-point function for the tensor mode \( h_{ij} \) can be calculated based on the in-in formalism \([36, 58]\),

\[
\langle h_{i1j1}(\tau, k_1)h_{i2j2}(\tau, k_2)h_{i3j3}(\tau, k_3) \rangle = i \int_{-\infty}^{\tau} d\eta \langle [H_{\text{int}}(\eta), h_{i1j1}(\tau, k_1)h_{i2j2}(\tau, k_2)h_{i3j3}(\tau, k_3)] \rangle.
\] (3.4)

From this three-point function, we define un-contracted bispectrum for later convenience as

\[
\langle h_{i1j1}(\tau, k_1)h_{i2j2}(\tau, k_2)h_{i3j3}(\tau, k_3) \rangle \equiv (2\pi)^3 \delta(k_1 + k_2 + k_3)B_{i1j1i2j2i3j3}(k_1, k_2, k_3),
\] (3.5)

where \( k_i \equiv |k_i| \). Taking the following sum over the indices, one can compute the tensor bispectrum from it,

\[
B_h(k_1, k_2, k_3) = \delta_{j_1j_2}\delta_{j_3j_4}\delta_{j_5j_6}B_{i1j1i2j2i3j3}(k_1, k_2, k_3).
\] (3.6)

The un-contracted bispectrum \( B_{i1j1i2j2i3j3} \) can be split into two parts which are contributed by \( H_{\text{int}}^{(\text{GR})} \) and \( H_{\text{int}}^{(\text{mass})} \), respectively, as

\[
B_{i1j1i2j2i3j3} = B_{i1j1i2j2i3j3}^{(\text{GR})} + B_{i1j1i2j2i3j3}^{(\text{mass})}.
\] (3.7)

Plugging eqs. (3.2) and (3.3) into (3.4), we obtain

\[
B_{i1j1i2j2i3j3}^{(\text{GR})} = -\frac{32}{a^3M_{\text{Pl}}^4} \mathcal{I}^{(\text{GR})}(k_1, k_2, k_3; \tau) \mathcal{E}_{i1j1i2j2i3j3}^{(\text{GR})}(\hat{k}_1, \hat{k}_2, \hat{k}_3),
\] (3.8)

\[
B_{i1j1i2j2i3j3}^{(\text{mass})} = \frac{192}{a^3M_{\text{Pl}}^4} \mathcal{I}^{(\text{mass})}(k_1, k_2, k_3; \tau) \mathcal{E}_{i1j1i2j2i3j3}^{(\text{mass})}(\hat{k}_1, \hat{k}_2, \hat{k}_3),
\] (3.9)

where \( \mathcal{I}^{(X)} \) are basically time integrals of the mode functions,

\[
\mathcal{I}^{(\text{GR})}(k_1, k_2, k_3; \tau) \equiv k_1^2 \int_{-\infty}^{\tau} d\eta a^{-1}(\eta) \operatorname{Im} \left[ v^*_k(\tau)v_k^*(\tau)v_{k_2}(\eta)v_{k_3}(\eta) \right],
\] (3.10)

\[
\mathcal{I}^{(\text{mass})}(k_1, k_2, k_3; \tau) \equiv \int_{-\infty}^{\tau} d\eta a(\eta)g(\eta) \operatorname{Im} \left[ v^*_k(\tau)v_k^*(\tau)v_{k_1}(\eta)v_{k_2}(\eta)v_{k_3}(\eta) \right],
\] (3.11)

while \( \mathcal{E}^{(X)} \) are combinations of the tensor polarizations,

\[
\mathcal{E}_{i1j1i2j2i3j3}^{(\text{GR})}(\hat{k}_1, \hat{k}_2, \hat{k}_3) = \left[ \Pi_{i1j1,ij}(\hat{k}_1)\Pi_{i2j2,kl}(\hat{k}_2) \left( \kappa_{ij}^{3,ij} \Pi_{i3j3,ik}(\hat{k}_3) - \frac{1}{2} \kappa_{ij}^{3,ij} \Pi_{i3j3,kl}(\hat{k}_3) \right) + 5 \text{ permutation terms w.r.t. } 1, 2, 3 \right],
\] (3.12)

\[
\mathcal{E}_{i1j1i2j2i3j3}^{(\text{mass})}(\hat{k}_1, \hat{k}_2, \hat{k}_3) = \Pi_{i1j1,ij}(\hat{k}_1)\Pi_{i2j2,ik}(\hat{k}_2)\Pi_{i3j3,ki}(\hat{k}_3)
\] (3.13)

with

\[
\kappa_i \equiv \frac{k_i}{k_1} \quad (i = 2, 3), \quad \Pi_{ij,kl}(\hat{k}) \equiv \sum_\lambda \epsilon_{ij}^\lambda(\hat{k})\epsilon_{kl}^\lambda(\hat{k}).
\] (3.14)

We shall also adopt the notation \( \kappa_i \equiv |\kappa_i| = k_i/k_1 \).
In what follows in this section, we will evaluate \( \mathcal{I}^{(X)} \). As discussed in appendix B, it can be shown that \( \mathcal{I}^{(X)} \) are well approximated by

\[
\mathcal{I}^{(GR)}(\tau) \simeq \text{Im} \left[ v_{k_1}(\tau)v_{k_2}(\tau)v_{k_3}(\tau) \right] k_1^2 \int_{-\infty}^{\tau} d\eta a^{-1}(\eta) \Re \left[ v_{k_1}(\eta)v_{k_2}(\eta)v_{k_3}(\eta) \right],
\]

\[
\mathcal{I}^{(mass)}(\tau) \simeq \text{Im} \left[ v_{k_1}(\tau)v_{k_2}(\tau)v_{k_3}(\tau) \right] \int_{-\infty}^{\tau} d\eta a(\eta) g(\eta) \Re \left[ v_{k_1}(\eta)v_{k_2}(\eta)v_{k_3}(\eta) \right].
\]

We will evaluate these time integrals and the prefactor \( \text{Im} [v_{k_1}v_{k_2}v_{k_3}] \) in section 3.1 and 3.2, respectively.

### 3.1 Evaluating time integral during inflation

Concentrating on the inflationary era, \( \tau < \tau_r \), one can rewrite the time integrals in eqs. (3.15) and (3.16) as

\[
\int_{-\infty}^{\tau} d\eta a^{-1}(\eta) \Re \left[ v_{k_1}(\eta)v_{k_2}(\eta)v_{k_3}(\eta) \right] = \frac{\pi^{3/2}}{8k_1^{3/2}} \left( \frac{H_{\text{inf}}}{k_1} \right)^{3/2} \mathcal{I}^{(GR/mass)},
\]

with dimensionless integrals

\[
\mathcal{I}^{(GR/mass)}(\kappa_2, \kappa_3) \equiv \int_{|k_1\tau_r|}^{\infty} dy y^{3/2} \Re \left[ H_{\nu}^{(1)}(y)H_{\nu}^{(1)}(\kappa_2y)H_{\nu}^{(1)}(\kappa_3y) \right] \]

where \( g(\eta) \) is assumed to be constant during inflation and \( y \equiv -k_1\eta \) is introduced as a new dummy variable. \( \mathcal{I}^{(GR/mass)} \) depends on \( \kappa_2, \kappa_3 \) and \( \nu = \sqrt{9/4 - m^2/H_{\text{inf}}^2} \) and should be numerically evaluated. In figure 1, we show their dependence on \( m/H_{\text{inf}} \) for the equilateral (\( \kappa_2 = \kappa_3 = 1 \)) and the squeezed (\( \kappa_3 \ll \kappa_2 = 1 \)) configurations. The following three observations are found in figure 1: (i) \( |\mathcal{I}^{(mass)}| \) is always larger than \( |\mathcal{I}^{(GR)}| \). (ii) The squeezed configuration (solid) is larger than the equilateral configuration (dashed). (iii) \( |\mathcal{I}^{(mass)}| \) increases as \( |k\tau_r| \) decreases for \( |k\tau_r| \lesssim 0.7 \), while \( |\mathcal{I}^{(GR)}| \) is insensitive to \( |k\tau_r| \lesssim 1 \).

Comparing \( \mathcal{I}^{(mass)} \) and \( \mathcal{I}^{(GR)} \), we find

\[
\frac{\mathcal{I}^{(mass)}}{\mathcal{I}^{(GR)}} = \frac{g_{\text{inf}}}{H_{\text{inf}}^2} \frac{\mathcal{I}^{(mass)}}{\mathcal{I}^{(GR)}},
\]

where \( g_{\text{inf}} \) is the value of \( g \) during inflation. Since \( \mathcal{I}^{(mass)} \) is larger than \( \mathcal{I}^{(GR)} \) by almost an order of magnitude as seen in figure 1, we expect that the contribution to the tensor bispectrum is dominated by \( B^{(mass)}_{i_1j_1i_2j_2i_3j_3} \) rather than \( B^{(GR)}_{i_1j_1i_2j_2i_3j_3} \), if \( g_{\text{inf}} \gtrsim H_{\text{inf}}^2 \). We will explicitly confirm this expectation with numerical computations in the next section.

One can also see in figure 1 that the squeezed configuration case is much larger than the equilateral case. We find that \( \mathcal{I}^{(GR/mass)} \) diverges in the squeezed limit as

\[
\lim_{\kappa_2 \to 1, \kappa_3 \to 0} \mathcal{I}^{(GR/mass)} \simeq -\lim_{\kappa_3 \to 0} \int_{|k_1\tau_r|}^{\infty} dy y^{3/2} \text{Im} \left[ \left( H_{\nu}^{(1)}(y) \right)^2 \right] \text{Im} \left[ H_{\nu}^{(1)}(\kappa_3y) \right]
\]

\[
= \lim_{\kappa_3 \to 0} \kappa_3^{-\nu} \times \left( \frac{2\nu \Gamma(\nu)}{\pi} \int_{|k_1\tau_r|}^{\infty} dy y^{3/2-\nu} \text{Im} \left[ \left( H_{\nu}^{(1)}(y) \right)^2 \right] \right). \tag{3.20}
\]

This implies that the tensor bispectrum peaks at the squeezed configuration, and the degree of divergence in the squeezed limit is solely determined by \( \nu = \sqrt{9/4 - m^2/H_{\text{inf}}^2} \).
Figure 1. The numerical results of $|J^{(X)}(\kappa_2, \kappa_3)|$ defined in eq. (3.18) with $X = \text{GR}$ (blue) and $X = \text{mass}$ (red and grey) are shown as functions of $m/H_{\text{inf}}$. The solid and dashed line denote the squeezed configuration ($\kappa_2 = 1, \kappa_3 = 0.1$) and the equilateral configuration ($\kappa_2 = \kappa_3 = 1$), respectively. The lower bound of the integral range of $|J^{(\text{mass})}|$ is $|k\tau_i| = 10^{-15}$ (red) and $10^{-5}$ (grey), while $|J^{(\text{GR})}|$ (blue) does not depend on it. $|J^{(\text{mass})}|$ is amplified for $m/H_{\text{inf}} \lesssim 0.7$ as $|k\tau_i|$ decreases.

Although $J^{(\text{GR})}$ is not sensitive to the lower limit of the integral, $|k\tau_i| \ll 1$, we found $J^{(\text{mass})}$ depends on it for $m/H_{\text{inf}} \lesssim 0.7$. Well after all the modes with $k_1, k_2, k_3$ exit the horizon, the integrand of $J^{(\text{GR/mass})}$ in eq. (3.18) evolve as,

$$y^{3\pm 1} \Re \left[ H^{(1)}_\nu(y)H^{(1)}_\nu(k_2y)H^{(1)}_\nu(k_3y) \right] \sim y^{3-\nu \pm 1}. \quad (3.21)$$

Hence, the massless limit ($\nu = 3/2$) of $J^{(\text{mass})}$ exhibits a logarithmic enhancement. Indeed, we can explicitly calculate $J^{(\text{mass})}$ in the massless limit as

$$\lim_{m \to 0} J^{(\text{mass})} = (1 + \kappa^3_3 + \kappa^3_3) (N_{k_1} - \gamma_E) + \frac{1}{3} (1 + \kappa_2 + \kappa_3) \left( 4 + 4\kappa^2_2 + 4\kappa^2_3 - \kappa_2 - \kappa_3 - \kappa_2 \kappa_3 \right), \quad (3.22)$$

where $N_{k_1} \equiv - \log |k_1 \tau_i|$ and $\gamma_E$ is Euler’s constant.\(^7\) Nevertheless, in this paper, we focus on the cases of $m/H_{\text{inf}} = O(1)$ with which we obtain the amplified blue-tilted GW power spectrum, eq. (2.10). Then, not only $J^{(\text{GR})}$ but also $J^{(\text{mass})}$ becomes constant for a sufficiently small $|k_1 \tau_i|$. Therefore, we can ignore the late time contribution to $J^{(\text{GR/mass})}$.

3.2 Evolution after inflation

Now we consider the factor $\text{Im} \left[ v^*_k(\tau)v^*_k(\tau)v^*_k(\tau) \right]$ in eqs. (3.15) and (3.16) which represents the post-inflationary evolution of the bispectrum. Evaluating at the end of inflation and using eq. (2.7) again, one finds

$$a^{-3}(\tau_r) \text{Im} \left[ v^*_k(\tau_r)v^*_k(\tau_r)v^*_k(\tau_r) \right] \sim \frac{2^{3\nu-3} \Gamma^3(\nu) H_{\text{inf}}^3 |k_1 \tau_i|^{3(3-2\nu)}}{\pi^{3/2} \kappa^3_2 \kappa^3_3 k_1^{3/2} 2^{3(3-2\nu)}}, \quad (3.23)$$

where $a^{-3}$ was multiplied because the bispectrum has this prefactor in eqs. (3.8) and (3.9) which originally comes from the fact, $h(\tau) \propto v(\tau)/a(\tau)$. The evolution after inflation is given

\(^7\)Basically this integral was calculated in ref. [34] (see eq. (72) of the paper). There are, however, a couple of typos in the paper including the absence of the term proportional to $N_{k_1}$. For these points, we contacted the authors of ref. [34] and we have got the agreement.
by a factor from eqs. (2.9) and (2.12)
\[
\frac{v_k(\tau)}{v_k(\tau_r)} = \sqrt{\frac{\tau_m}{\tau_r}} \frac{a(\tau)}{a(\tau_r)} T_k(\tau).
\] (3.24)

Now we obtain
\[
a^{-3(\tau)} \Im \left[ v_k^*(\tau) v_k^*(\tau) v_k^*(\tau) \right] \simeq H_{\text{inf}}^3 \frac{T_k(\tau) T_k(\tau) T_k(\tau)}{2^{3/2} k_1^2 \kappa_3^2 k_2^2} \tilde{\gamma}_1 \tilde{\gamma}_2 \tilde{\gamma}_3 \left[ |k_1 \tau_r| (3-2\nu) \frac{\tau_m}{\tau_r} \right]^{3/2}.
\] (3.25)

Here, the last factor \(\tilde{\gamma}_1 \tilde{\gamma}_2 \tilde{\gamma}_3 \) is given by \([59]\)
\[
\tilde{\gamma}_1 \tilde{\gamma}_2 \tilde{\gamma}_3 = \frac{1}{\sqrt{\tau_m/\tau_0}} \frac{j_1(k_0 \tau_0)}{k_0 \tau_0} T_1(k/k_0) \frac{g_{*0}}{g_{*-0}(T_{\text{in}})} \left( \frac{g_{*0}}{g_{*-0}(T_{\text{in}})} \right)^{2/3} \frac{3j_1(k_0 \tau_0)}{k_0 \tau_0},
\] (3.26)

where \(j_1(x) = (\sin(x)/x - \cos(x))/x\), \(T_1(x) = 1 + 1.57x + 3.42x^2\), \(T_{\text{in}}\) is the temperature of the universe when the mode reenters the horizon and \(k_0 = 7.1 \times 10^{-2} \Omega m_0 h^2 \text{Mpc}^{-1}\) is the wavenumber corresponding to the horizon scale of the matter-radiation equality.

### 3.3 Tensor bispectrum today

Putting the results of the previous subsections altogether, we obtain the two contributions to the contracted bispectrum at the present time as
\[
k_1^2 k_2^2 k_3^2 B_h^{(\text{GR})} = \frac{1}{2} (2\pi)^{3/2} H_{\text{inf}}^4 \frac{E^{(\text{GR})} T^{(\text{GR})}}{M^4 P_4} T_1 \frac{T_2 T_3 (\tau_0) \tilde{\gamma}_1 \tilde{\gamma}_2 \tilde{\gamma}_3}{|k_1 \tau_r| (3-2\nu) \frac{\tau_m}{\tau_r}}^{3/2},
\] (3.27)
\[
k_1^2 k_2^2 k_3^2 B_h^{(\text{mass})} = 3(2\pi)^{3/2} g_{*0} \frac{H_{\text{inf}}^2}{M^4 P_4} \frac{E^{(\text{mass})} T^{(\text{mass})}}{\kappa_2 \kappa_3} T_1 \frac{T_2 T_3 (\tau_0) \tilde{\gamma}_1 \tilde{\gamma}_2 \tilde{\gamma}_3}{|k_1 \tau_r| (3-2\nu) \frac{\tau_m}{\tau_r}}^{3/2},
\] (3.28)

where we multiplied \(B_h^{(\text{GR/mass})}\) by \((k_1 k_2 k_3)^2\) in order to make them dimensionless. Here, the contracted polarization tensors \(E^{(\text{GR/mass})}\) are computed as
\[
E^{(\text{GR})} = \frac{1}{1024 \kappa_2 \kappa_3} \left( \kappa_2^2 - 2 \kappa_2^2 (\kappa_3^2 + 1) + (\kappa_3^2 - 1)^2 \right)^2 \left[ \kappa_2^6 + 15 \kappa_2^4 (\kappa_3^2 + 1) + 15 \kappa_3^2 (\kappa_3^2 + 6 \kappa_3^2 + 1) + (\kappa_3^2 + 15 \kappa_3^2 + 15 \kappa_3^2 + 1)^2 \right],
\] (3.29)
\[
E^{(\text{mass})} = \frac{1}{512 \kappa_2 \kappa_3} \left( -2 (\kappa_2^2 + 1) \kappa_3^2 + (\kappa_2^2 - 1)^2 + \kappa_3^2 \right)^2 \left( \kappa_2^2 + 6 \kappa_3^2 (\kappa_3^2 + 1) + \kappa_3^4 + 6 \kappa_3^2 + 1 \right).
\] (3.30)

For instance, their values at the squeezed and equilateral configurations are
\[
E^{(\text{GR})} = \frac{1}{2}, \quad E^{(\text{mass})} = \frac{1}{4}, \quad \text{(Squeezed : } \kappa_2 = 1, \kappa_3 \to 0) \tag{3.31}
\]
\[
E^{(\text{GR})} = \frac{1647}{1024}, \quad E^{(\text{mass})} = \frac{189}{512}, \quad \text{(Equilateral : } \kappa_2 = \kappa_3 = 1) \tag{3.32}
\]
Figure 2. The shape functions $S^{(\text{GR})}$ (left panel) and $S^{(\text{mass})}$ (right panel) defined in eq. (3.33) are shown for $m/H_{\text{inf}} = 0.8$. Both of them diverge at the squeezed limit, $\kappa_2 \to 1$ and $\kappa_3 \to 0$.

We can also define their shape functions as

$$S^{(X)}(\kappa_2, \kappa_3) = \mathcal{N}^{(X)}(\kappa_2^2 - \nu \kappa_3^2 - \nu) \mathcal{E}^{(X)}(\kappa_2, \kappa_3) \mathcal{J}^{(X)}(\kappa_2, \kappa_3), \quad (X = \text{GR/mass})$$

(3.33)

where the factor $\mathcal{N}^{(X)} = \left[ \mathcal{E}^{(X)}(\kappa_2 = \kappa_3 = 1) \right]^{-1}$ normalizes the shape function at the equilateral configuration such that $S^{(X)}(\kappa_2 = \kappa_3 = 1) = 1$. From eq. (3.20), one finds that the asymptotic behavior of the shape functions in the squeezed limit is the same for the two contributions,

$$\lim_{\kappa_2 \to 1, \kappa_3 \to 0} S^{(X)}(\kappa_2, \kappa_3) \propto \kappa_2^{2-2\nu}, \quad (X = \text{GR/mass})$$

(3.34)

and $(k_1 k_2 k_3)^2 B_h$ diverges in the squeezed limit for $\nu > 1 \iff m/H_{\text{inf}} < \sqrt{5}/2 \approx 1.12$.

Let us compare the amplitudes of the two contributions, $B_h^{(\text{mass})}$ and $B_h^{(\text{GR})}$. Their ratio is given by

$$\left| \frac{B_h^{(\text{mass})}}{B_h^{(\text{GR})}} \right| = 6 g_{\text{inf}} H_{\text{inf}}^2 \left| \frac{\mathcal{E}^{(\text{mass})} \mathcal{J}^{(\text{mass})}}{\mathcal{E}^{(\text{GR})} \mathcal{J}^{(\text{GR})}} \right| \gtrsim \frac{6 g_{\text{inf}}}{H_{\text{inf}}^2}.$$

(3.35)

Here, $|\mathcal{E}^{(\text{mass})} \mathcal{J}^{(\text{mass})}/\mathcal{E}^{(\text{GR})} \mathcal{J}^{(\text{GR})}|$ is plotted in figure 3 and is shown to be larger than unity irrespective of $m/H_{\text{inf}}$ or configuration. Therefore, for $g_{\text{inf}}/H_{\text{inf}}^2 = O(1)$, the new contribution to the bispectrum $B_h^{(\text{mass})}$ dominates the conventional one $B_h^{(\text{GR})}$.

It is interesting to note that the bispectrum divided by the square root of the power spectra can be written in a simple expression,

$$\frac{(k_1 k_2 k_3)^2 B_h(k_1, k_2, k_3)}{[P_h(k_1) P_h(k_2) P_h(k_3)]^{1/2}} \approx \frac{3 \pi^{9/2} g_{\text{inf}}}{H_{\text{inf}} M_{\text{Pl}}} \mathcal{E}^{(\text{mass})} \mathcal{J}^{(\text{mass})}(\kappa_2 \kappa_3)^{\frac{7}{2} - 2\nu},$$

(3.36)

where the sub-leading contribution from $B_h^{(\text{GR})}$ is ignored. Here, the common factor discussed below eq. (3.25) which enhances both the power spectrum and bispectrum is cancelled out.

At this stage, it is worth pointing out one subtlety about the bispectrum from $H_{\text{inf}}^{(\text{mass})}$ calculated in this section. In [60], it was shown that the tensor bispectrum satisfying Maldacena’s consistency relation [36] obtained in usual GR can be removed by a gauge transformation. In this case, the calculated bispectrum is not physical but just artifact for a local observer (see also [61, 62]). On the other hand, for the bispectrum generated by solid inflation [29, 30], it was shown in [63, 64] that the Maldacena’s consistency relation does not hold.
for the tensor squeezed bispectrum and one cannot remove it by gauge transformations. In other words, the calculated bispectrum is observable in solid inflation. Here, since our setup can be regarded as a generalization of solid inflation, which in the unitary gauge does not respect the spatial diffeomorphism, it is natural for us to expect that the contribution from the mass term $H_{\text{int}}^{(\text{mass})}$ which is absent in the GR limit to the tensor bispectrum cannot be removed by gauge transformations. Therefore, we will assume in this paper that the calculated bispectrum $B_h^{(\text{mass})}$ is not a gauge artifact but an actual observable.

4 Quadrupolar modulation of tensor power spectrum

In this section we discuss the detectability of the primordial tensor bispectrum calculated in the previous section. Although it seems that the simplest way to detect the tensor bispectrum is the direct measurement of it at interferometer scales, it was shown that the bispectrum cannot be probed directly [50, 51]. Instead of this, we briefly discuss the detectability based on the modulation of the tensor power spectrum induced by the squeezed tensor bispectrum.

The tensor power spectrum with polarization $\lambda_1$ modulated by a long tensor mode with polarization $\lambda_3$ and wavevector $k_3$ is given by

$$\lim_{k_3 \to 0} \langle h_{k_1}^{\lambda_1} h_{k_2}^{\lambda_1} h_{k_3}^{\lambda_3} \rangle' \simeq \langle h_{k_1}^{\lambda_1} h_{k_2}^{\lambda_1} \rangle' + \lim_{k_3 \to 0} \left( \frac{h_{k_3}^{\lambda_3} \langle h_{k_1}^{\lambda_1} h_{k_2}^{\lambda_1} h_{k_3}^{\lambda_3} \rangle'}{P_h^{\lambda_3}(k_3)} \right),$$

(4.1)

where the prime on the expectation value $\langle \cdots \rangle'$ indicates that the momentum conserving delta function and a factor of $(2\pi)^3$ are removed. Here, the power spectrum is given by

$$P_h^{\lambda}(k) = \frac{2H_{\inf}^2}{M_{\text{Pl}}^2 k^3} \mathcal{D}_k^2(\tau_0) \gamma_k^2 |k\tau_r|^{-2}(3-2\nu) \frac{\tau_m}{\tau_r},$$

(4.2)

where the two polarizations are not summed over and $P_h(k) = 2P_h^{\lambda}(k)$ in our model.

---

8For recent discussions on the implication of the violation of Maldacena’s consistency relation in solid inflation, see [65, 66].
From the definition of tensor bispectrum shown in eq. (3.5), one finds
\[
\langle h_{k_1}^{\lambda_1} h_{k_2}^{\lambda_2} h_{k_3}^{\lambda_3} \rangle = e^{\lambda_1 \ast}_{ij} \tilde{(k_1)} e^{\lambda_2 \ast}_{kl} \tilde{(k_2)} e^{\lambda_3 \ast}_{mn} \tilde{(k_3)} B_{ijklmn}(k_1, k_2, k_3)
\]
\[
\simeq \frac{192}{a^3 \mathcal{M}_p^3} \mathcal{L}^{(\text{mass})} e^{\lambda_1 \ast}_{ij} \tilde{(k_1)} e^{\lambda_2 \ast}_{kl} \tilde{(k_2)} e^{\lambda_3 \ast}_{mn} \tilde{(k_3)} \mathcal{E}^{(\text{mass})}_{ijklmn}(k_1, k_2, k_3)
\]
\[
= \frac{192}{a^3 \mathcal{M}_p^3} \mathcal{L}^{(\text{mass})} e^{\lambda_1 \ast}_{ij} \tilde{(k_1)} e^{\lambda_2 \ast}_{jk} \tilde{(k_2)} e^{\lambda_3 \ast}_{ki} \tilde{(k_3)},
\]
(4.3)
where we ignored the subdominant contribution from the GR interaction in the second line. This equation can be reduced by summing over $\lambda_1$ in the squeezed limit,
\[
\lim_{k_3 \to 0} \sum_{\lambda_1} \langle h_{k_1}^{\lambda_1} h_{k_2}^{\lambda_2} h_{k_3}^{\lambda_3} \rangle \simeq \lim_{k_3 \to 0} \frac{-192}{a^3 \mathcal{M}_p^3} \mathcal{L}^{(\text{mass})} e^{\lambda_3 \ast}_{ij} \tilde{(k_3)} \tilde{k}_1^i \tilde{k}_1^j
\]
\[
= \lim_{k_3 \to 0} \frac{-3\pi^{3/2} g_{\text{inf}}}{2 \mathcal{H}_{\text{inf}} \mathcal{M}_p k_1^{3/2}} P_h(k_1) \sqrt{P_h^3(k_3)} \mathcal{J}^{(\text{mass})} e^{\lambda_3 \ast}_{ij} \tilde{(k_3)} \tilde{k}_1^i \tilde{k}_1^j.
\]
(4.4)
where $\sum_{\lambda} e^{\lambda \ast}_{ij}(k) e^{\lambda}_{kl}(k) = \delta_{kl} - \tilde{k}_l \tilde{k}_l$ is used in the first line.
Substituting it into eq. (4.1), the observable power spectrum taking into account the presence of the long tensor mode $h_{k_3}^{\lambda_3}$ has the following quadrupole modulation
\[
\lim_{k_3 \to 0} \frac{P_h(k_1)}{P_h^3(k_3)} \text{[obs]} \simeq \lim_{k_3 \to 0} P_h(k_1) \left( 1 + \bar{f}_{\text{NL}}^{\lambda_3}(k_3) h_{k_3}^{\lambda_3} e^{\lambda_3 \ast}_{ij} \tilde{(k_3)} \tilde{k}_1^i \tilde{k}_1^j \right)
\]
\[
\equiv \lim_{k_3 \to 0} P_h(k_1) \left( 1 + \bar{Q}_{ij}(k_3) \tilde{k}_1^i \tilde{k}_1^j \right),
\]
(4.5)
with
\[
\bar{f}_{\text{NL}}^{\lambda_3}(k_3) \equiv \frac{-3\pi^{3/2} g_{\text{inf}}}{2 \mathcal{H}_{\text{inf}} \mathcal{M}_p k_1^{3/2}} \mathcal{J}^{(\text{mass})} P_h^3(k_3).
\]
(4.6)
Then, the observed quadrupole in the tensor power spectrum can be obtained by summing over both long-mode polarizations $\lambda_3 = \pm$ and wave vector $k_3$,
\[
Q_{ij}(x) = \lim_{k_3 \to 0} \int \frac{d^3 k_3}{(2\pi)^3} e^{i k_3 \cdot x} \sum_{\lambda_3} \bar{Q}_{ij}^{\lambda_3}(k_3).
\]
(4.7)
Note that the lower limit of the integral in the above equation is given by the scale corresponding to the infrared cutoff which is, however, not relevant in our case. The expectation value of the quadrupole moments squared can be calculated as
\[
(\mathcal{Q})^2 \equiv \frac{8\pi}{15} \langle Q_{ij}(x) Q_{ij}(x) \rangle = \lim_{k_3 \to 0} \frac{8\pi}{15} \int \frac{d^3 k_3}{(2\pi)^3} \sum_{\lambda_3} \langle \bar{Q}_{ij}^{\lambda_3 \ast}(k_3) \bar{Q}_{ij}^{\lambda_3}(k_3) \rangle
\]
\[
= \lim_{k_3 \to 0} \frac{4}{15\pi} \int d k_3 k_3^2 \sum_{\lambda_3} \left( \bar{f}_{\text{NL}}^{\lambda_3}(k_3) \right)^2 P_h^{\lambda_3}(k_3)
\]
\[
= \frac{6\pi^2}{5} \left( \frac{g_{\text{inf}}}{\mathcal{H}_{\text{inf}} \mathcal{M}_p} \right)^2 \int d k_3 k_3^2 \left( \mathcal{J}^{(\text{mass})} \right)^2.
\]
(4.8)
Figure 4. Plots of $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$ that gives $\sqrt{Q} = 10^{-2}$ as functions of $m/H_{\text{inf}}$. The color scheme is orange for $\kappa_{\text{UV}} = 10^{-15}$ and blue for $\kappa_{\text{UV}} = 10^{-8}$, which roughly correspond to LISA and SKA, respectively. The lower bound of the $\kappa_3$ integral is taken as $10^{-15} \kappa_{\text{UV}}$. 

Using eq. (3.20), this integral is evaluated as

$$
\int_{\kappa_3}^{\kappa_{\text{UV}}} \kappa_3^2 \left[ \mathcal{J}^{(\text{mass})} \right]^2 \simeq G \left( \frac{m}{H_{\text{inf}}} \right) \frac{\kappa_{\text{UV}}^{3-2\nu}}{3-2\nu},
$$

with

$$
G \left( \frac{m}{H_{\text{inf}}} \right) = \left( \frac{2^{\nu} \Gamma(\nu)}{\pi} \right) \left[ \frac{1}{k_{1.7}} \right]^3 \int_{y_1}^{y_2} dy y^{\frac{3}{2} - \nu \pm 1} \text{Im} \left( \left( H^{(1)}_{\nu'}(y) \right)^2 \right) \right)^2

\approx \exp \left[ 1.80919 \left( \frac{m}{H_{\text{inf}}} \right)^3 - 2.01653 \left( \frac{m}{H_{\text{inf}}} \right)^2 - 4.96751 \left( \frac{m}{H_{\text{inf}}} \right) + 5.58025 \right],
$$

where $\kappa_{\text{UV}}$ denotes UV cutoff of $\kappa_3$ and a numerical fit is used in the second line. It is worth mentioning that the concrete value of $\kappa_{\text{UV}}$ depends on the target scale at which we expect to observe the quadrupole modulation. For example, by assuming that $k_3$ is slightly larger than the horizon scale today, for the scale corresponding to interferometers like LISA, $\kappa_{\text{UV}} \simeq 10^{-15}$, while for the one corresponding to pulsar timing arrays like SKA, $\kappa_{\text{UV}} \simeq 10^{-8}$.

Combining all results in this section so far, $g_{\text{inf}}$ can be expressed as\footnote{For the present case with $m/H_{\text{inf}} = \mathcal{O}(1)$, a theoretically natural choice for the value of $g_{\text{inf}}$ would be of order $\mathcal{O}(H_{\text{inf}}^2)$, which can be different from $\mathcal{O}(H_{\text{inf}}M_{\text{Pl}})$. Moreover, theoretical considerations such as the positivity bound may lead to some constraints on the range of $g_{\text{inf}}$. However, in the present paper, we instead adopt the purely phenomenological standpoint and discuss the interesting range of $g_{\text{inf}}$ for on-going/future experiments. For this purpose it is convenient to put bounds on $g_{\text{inf}}$ in the unit of $H_{\text{inf}}M_{\text{Pl}}$ instead of $H_{\text{inf}}^2$, assuming that $H_{\text{inf}}$ is not too different from $M_{\text{Pl}}$.}

$$
\frac{g_{\text{inf}}}{H_{\text{inf}}M_{\text{Pl}}} = \sqrt{\frac{5}{6\pi^2}} \sqrt{\langle Q \rangle^2} \left( \frac{3 - 2\nu}{\kappa_{\text{UV}}^{3-2\nu}} \right) \frac{1}{2} G \left( \frac{m}{H_{\text{inf}}} \right)^{-\frac{1}{2}},
$$

According to recent discussions on the quadrupole modulation induced by the tensor bispectrum, it was suggested that the quadrupole can be observed if $\sqrt{\langle Q \rangle^2} \gtrsim 10^{-2}$ [67, 68] on
small scales, where the tensor power spectrum is observable. In figure 4, numerical plots of $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$ that give $\sqrt{\langle Q \rangle^2} = 10^{-2}$ are shown. If the value of $g_{\text{inf}}$ for given $m/H_{\text{inf}}$ is greater than the one shown by the plots, the modulation can be proved at the interferometer scale (the orange plot with $\kappa_{\text{UV}} = 10^{-15}$) or the scale of pulsar timing arrays (the blue plot with $\kappa_{\text{UV}} = 10^{-8}$).

Making use of the expression (4.11), the dependence of $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$ on $\kappa_{\text{UV}}$ and $m/H_{\text{inf}}$ can be understood as follows. For a fixed $m/H_{\text{inf}}$, its power on $\kappa_{\text{UV}}$ is $-3/2 + \nu$ that is negative for $0 < \nu < 3/2$. Then, for $\kappa_{\text{UV}}$ that is positive and much smaller than 1, a larger $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$ is required for the detectability with a smaller $\kappa_{\text{UV}}$. On the other hand, for a fixed $\kappa_{\text{UV}}$, from the second line of (4.10), we can show that $(G(m/H_{\text{inf}}))^{-1/2}$ is an increasing function of $m/H_{\text{inf}}$ for the region shown in figure 4, which means that a larger $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$ is required for the detectability with a larger $m/H_{\text{inf}}$. Qualitatively, both of these features can be explained by the fact that the tensor power spectrum is blue-tilted, where the effect of the super horizon mode crucial for the modulation is suppressed for smaller $\kappa_{\text{UV}}$ with fixed $m/H_{\text{inf}}$ or for larger $m/H_{\text{inf}}$ with fixed $\kappa_{\text{UV}}$. Then, for large $m/H_{\text{inf}}$, the detectability requires a very large value of $g_{\text{inf}}/(H_{\text{inf}}M_{\text{Pl}})$, which needs an enormous fine-tuning, but for small $m/H_{\text{inf}}$, we do not need such a fine-tuning. For example, for $m/H_{\text{inf}} = 0.5$, which still gives interesting results on the tensor power spectrum [16], in order to obtain $\sqrt{\langle Q \rangle^2} \gtrsim 10^{-2}$, observable at the interferometer scale, we just need

$$
\frac{g_{\text{inf}}}{H_{\text{inf}}M_{\text{Pl}}} \gtrsim 10^{-2}.
$$

(4.12)

5 Conclusions and discussions

Recently, based on the minimal theory of massive gravity (MTMG), we proposed a new scenario predicting blue-tilted and largely amplified primordial gravitational waves (GWs) [16]. In the scenario, the primordial GWs can be detected by interferometer experiments, even if their signal is not observed at the CMB scale. While the analysis in ref. [16] was limited to the linear perturbation related with the tensor power spectrum, since there are many other possible sources producing the GWs detectable at the interferometer scales, it is important to clarify how to distinguish our scenario from others. In this paper, as a natural extension of the previous analysis, we have considered the non-Gaussianity of primordial GWs in the scenario with the special emphasis on the tensor bispectrum.

We have shown that in MTMG, the interaction Hamiltonian for the tensor perturbation at the third order has two contributions, where one has the same form as the usual one derived from general relativity (GR) and the other is peculiar to MTMG. With this interaction Hamiltonian, we have calculated the tensor bispectrum based on the in-in formalism. Our method to obtain the tensor bispectrum today can be separated into the following two steps. The first step is evaluating the time integral in the in-in formalism during inflation. At this step, since the form of the interaction Hamiltonian peculiar to MTMG is the same as the one appearing in supersolid inflation, the calculation of this part itself is not new, while we have presented new results for the parameter region with the graviton mass comparable to the Hubble expansion rate during inflation. The second step is taking into account the enhancement of the GWs after inflation that is crucial in our scenario and is new. Combing these together, we have found that the contribution from the three-point interaction peculiar to MTMG dominates the one derived from GR and that the resultant tensor bispectrum peaks at the squeezed limit whose slope is determined by the graviton mass.
We have also considered the detectability of this tensor bispectrum. Since it had been shown in the literature that the bispectrum cannot be probed directly at interferometer scales, we have instead discussed the detectability based on the quadrupolar modulation of the tensor power spectrum, which is induced by the squeezed tensor bispectrum, making use of the well-known idea of the tensor fossils. We have shown that for $m/H_{\text{inf}} = 0.5$, which is sufficient to generate a blue-tilted and amplified tensor power spectrum detectable at the interferometer scales, if $g_{\text{inf}}$, the coefficient of the three-point interaction peculiar to MTMG with the dimension of mass squared, is larger than $10^{-2}H_{\text{inf}}M_{\text{Pl}}$, which is natural for $H_{\text{inf}}$ not so smaller than $M_{\text{Pl}}$, the quadrupolar modulation sourced by the squeezed tensor bispectrum is observable.

The appearance of the quadrupolar modulation of the tensor power spectrum is related with the Maldacena’s consistency relation on the squeezed limit of the tensor three-point function [36] with which it was shown that tensor modes with wavelengths much longer than the present Hubble radius are unobservable [60]. Actually, for the setup of solid inflation, in ref. [69], it was shown that the appearance of the quadrupolar modulatoin is related with the fact that the Maldacena’s consistency relation is violated in the model [63, 64]. It is interesting to see if the consistency relation is violated or not in the scenario we considered whose setup can be regarded as generalization of solid inflation, explicitly.

In this paper, we have restricted ourselves to the case where the massive graviton is the only spin-2 particle. On the other hand, recently, from the viewpoint of cosmological collider [70, 71], the possibility that there are extra new particles in the very high energy regime like during inflation has been actively explored. Although most of works so far are intended to find particles with spin less than 2, some phenomenology is investigated for the case with extra spin-2 particles [67, 72–80]. The generalization of the current work to this direction might be worth investigating.

Finally, in this paper, as an extension of [16], where the amplitude of tensor power spectrum is large at the interferometer scales, but small at the CMB scale, we have not considered the possibility that the tensor bispectrum in this model is detectable by on-going CMB experiments. However, for some parameter region, it is possible that the amplitude of the tensor bispectrum is sufficiently large at the CMB scale, while that of the tensor power spectrum is not. So far, the detectability of tensor bispectra by CMB experiments are discussed for only very limited types of the tensor bispectra whose forms are well approximated by given templates (see [81], for a review) and the tensor bispectrum generated in our model does not fall into such classes. Therefore, it might be also interesting to consider the detectability of the tensor bispectrum in this model by CMB experiments. We would like to leave these topics for future work.

A Graviton mass and coupling constant in MTMG theory

In the main text, we have studied primordial tensor non-Gaussianity from massive gravity which predicts blue-tilted and largely amplified gravitational waves without relying on details of a concrete theory. On the other hand, MTMG [20, 21], which has a mass scale \( m \) and three dimensionless parameters \( c_i \) \((i = 1, 2, 3)\), is a concrete example giving such interesting phenomenology. Therefore, here, we express the tensor graviton mass \( \mu \) and coupling constant \( g \) in terms of the parameters in MTMG. The FLRW cosmology in this theory has two branches of solutions, the self-accelerating branch and the normal branch. In the self-accelerating branch, the effective cosmological constant is given by

\[
\Lambda_{\text{eff}} = \frac{m^2}{2} X (c_1 X^2 + 3 c_2 X + c_3),
\]

(A.1)

where \( X \) is a constant satisfying \( c_1 X^2 + 2 c_2 X + c_3 = 0 \). In this set-up, it was shown that the squared mass of graviton is given by

\[
\mu^2 = \frac{m^2}{2} X \left[ c_2 X + c_3 + \frac{H}{H_f} (c_1 X + c_2) \right],
\]

(A.2)

where \( H_f \) is the Hubble expansion rate of the fiducial metric and it can be freely specified. The self-coupling constant of the cubic interaction is given by

\[
g = -\frac{m^2}{24} X \left[ c_2 X - c_3 + \frac{H}{H_f} (c_1 X - c_2) \right].
\]

(A.3)

B Real part versus imaginary part

In this section, we derive the approximation in eqs. (3.15) and (3.16). The integrals in eqs. (3.10) and (3.11) are evaluated at the end of inflation as

\[
\int_{-\infty}^{\tau_r} d\eta \, a^{\mp 1}(\eta) \text{Im} \left[ v_{k_1}^* (\tau) v_{k_2}^* (\tau) v_{k_3}^* (\tau) v_{k_4} (\eta) v_{k_4} (\eta) v_{k_5} (\eta) \right] = \mathcal{I}_{\text{im}} + \mathcal{I}_{\text{re}},
\]

(B.1)

with

\[
\mathcal{I}_{\text{im}} = \text{Im} \left[ v_{k_1}^* (\tau) v_{k_2}^* (\tau) v_{k_3}^* (\tau) v_{k_4} (\eta) v_{k_4} (\eta) v_{k_5} (\eta) \right] \int_{-\infty}^{\tau_r} d\eta \, a^{\mp 1}(\eta) \text{Re} \left[ v_{k_1} (\eta) v_{k_2} (\eta) v_{k_3} (\eta) \right],
\]

\[
\mathcal{I}_{\text{re}} = \text{Re} \left[ v_{k_1}^* (\tau) v_{k_2}^* (\tau) v_{k_3}^* (\tau) v_{k_4} (\eta) v_{k_4} (\eta) v_{k_5} (\eta) \right] \int_{-\infty}^{\tau_r} d\eta \, a^{\mp 1}(\eta) \text{Im} \left[ v_{k_1} (\eta) v_{k_2} (\eta) v_{k_3} (\eta) \right].
\]

(B.2)

Since its integrand increases in time, \( \mathcal{I}_{\text{re}} \) is analytically performed with the super-horizon asymptotic form of the mode function as

\[
\mathcal{I}_{\text{re}} = \text{Re} \left[ v_{k_1}^* (\tau) v_{k_2}^* (\tau) v_{k_3}^* (\tau) \right] \int_{-\infty}^{\tau_r} d\eta \, a^{\mp 1}(\eta) \text{Im} \left[ v_{k_1} (\eta) v_{k_2} (\eta) v_{k_3} (\eta) \right]
\]

\[
= \text{Re} \left[ v_{k_1}^* (\tau) v_{k_2}^* (\tau) v_{k_3}^* (\tau) \right] \frac{2^{3(\nu-1)} \Gamma^3 (\nu)}{\pi^{3/2} k_1^{5/2} (k_2 k_3)^\nu} \left( \frac{k_1}{H_{\text{inf}}} \right)^{\mp 1} \int_{|k_1 \tau_r|}^{\infty} \frac{d y y^{\mp 1 - 3 \nu}}{y^{5/2} + \frac{1}{2} + 3 \nu} a_{\mp 1}^* (1 + \kappa_2^{\nu} + \kappa_3^{2\nu}),
\]

(B.3)
where \( m/H_{\text{inf}} < 0.94 \) is assumed to simplify \( \int dy y^{-3\nu+5/2} \). Using eq. (3.17), one finds

\[
\begin{align*}
\mathcal{I}_{\text{re}} & \simeq \frac{2^{2\nu} \Gamma(\nu)(1 + \kappa_2^2 \nu + \kappa_3^2 \nu^3)}{\Gamma(\nu + 1)(\kappa_2 \kappa_3)^{\nu} \mathcal{F}(\text{GR/mass})} \left| k_1 \tau_1 \right|^{2 - \nu \pm 1} \frac{5}{2} + 1 - 3\nu.
\end{align*}
\]

The factor \( \left| k_1 \tau_1 \right|^{2 - \nu \pm 1} \) is tiny in the massive case. Therefore, this shows \( \mathcal{I}_{\text{re}} \ll \mathcal{I}_{\text{im}} \) which justifies the approximation in eqs. (3.15) and (3.16).
