Abstract

Background: The CCND1 gene generates two mRNAs (cyclin D1a and D1b) through an alternative splicing at the site of a common A/G polymorphism. Cyclin D1a and b proteins differ in their C-terminus, a region involved in protein degradation and sub-cellular localization. Recent data have suggested that cyclin D1b could be a nuclear oncogene. The presence of cyclin D1b mRNA and protein has been studied in two hemopathies in which cyclin D1 could be present: multiple myeloma (MM) and mantle cell lymphoma (MCL). The A/G polymorphism of CCND1 has also been verified in a series of patients.

Methods: The expression of cyclin D1 mRNA isoforms has been studied by real-time quantitative PCR; protein isoforms expression, localization and degradation by western blotting. The CCND1 polymorphism was analyzed after sequencing genomic DNA.

Results: Cyclin D1 mRNA isoforms a and b were expressed in mantle cell lymphoma (MCL) and multiple myeloma (MM). Cyclin D1b proteins were present in MCL, rarely in MM. Importantly, both protein isoforms localized the nuclear and cytoplasmic compartments. They displayed the same short half-life. Thus, the two properties of cyclin D1b recognized as necessary for its transforming activity are missing in MCL. Moreover, CCND1 polymorphism at the exon/intron boundary had no influence on splicing regulation in MCL cells.

Conclusion: Our results support the notion that cyclin D1b is not crucial for the pathogenesis of MCL and MM.

Background

Cyclin D1 is a critical regulator of the cell cycle and transcriptional processes. Overexpression or overactivity of cyclin D1 is common in human cancers. Cyclin D1 is also expressed in lymphoid tumors such as mantle cell lymphoma (MCL) and multiple myeloma (MM). The expression of cyclin D1 in B-cells in which the protein is physiologically absent, is supposed to be causal in the transformation process. In MCL, CCND1 (encoding cyclin D1) is activated by the t(11;14)(q13;q32) in almost 100% of cases [1]. In multiple myeloma (MM), cyclin D1 is expressed in 45–50% of samples but the
t(11;14)(q13;q32) is only present in 15% of them [2]. The human \textit{CCND1} gene encodes two mRNAs species resulting from an alternative splicing: form a [3] and form b generated by the absence of splicing at the exon 4/intron 4 boundary [4]. Cyclin D1 protein isoforms differ in the last 55 amino acids of the carboxy-terminus. Cyclin D1a and D1b proteins possess the cyclin box necessary for cyclin-dependent kinase (CDK) binding and enzymatic activity. But the PEST destruction box as well as Thr286, the phosphorylation site of glycogen synthase kinase-3\(\beta\) which promotes the nuclear export of cyclin D1 and its turn-over, are missing in form b [5,6]. Recently, it has been shown that cyclin D1 isoforms could display functional differences and importantly that only cyclin D1b facilitates transformation in fibroblasts [7-9]. Considering this putative role in tumorigenesis, we have studied cyclin D1b expression in MCL and MM samples. A common A/G polymorphism described as a modulator of cancer risk is thought to regulate the production of cyclin D1b [4]. We have also analyzed this relationship in MCL samples.

**Methods**

**MCL and MM patients and cell lines**

Patients with MCL or MM were diagnosed according to criteria from the World Health Organization classification in our institution (CHU Côte de Nacre, Caen, France); their clinical features are presented in the Additional file 1. Signed informed consent was obtained from all patients before all procedures as required by the institutional review board. Peripheral blood or bone marrow samples were obtained at diagnosis. Mononuclear cells were isolated by centrifugation over a Ficoll-Hypaque layer. CD19+ cells from 10 MCL patients were then purified (>90%) using a MACS microbeads system (Miltenyi Biotechnology). CD138+ cells from 6 MM patients were purified with the same system (purity >85%). JeKo-1, NCEB-1, HBL-2 and GRANTA-519 are MCL cell lines. Karpos 620, U266, NCI-H929, RPMI 8226, OPM-2 are MM cell lines. As previously reported by us, they all expressed cyclin D1 except OPM-2. Cell lines were maintained in RPMI 1640 medium supplemented with 2 mM L-glutamine, 10% heat-inactivated fetal calf serum and antibiotics.

**Real-time quantitative RT-PCR**

Total RNA was isolated from purified MCL and MM cells and cell lines with the RNeasy Micro Kit (QIAGEN S.A.) and reverse-transcribed with the 1st Strand cDNA Synthesis kit (Roche). Real-time quantitative RT-PCR was performed on an ABI PRISM 7700 Sequence Detector with the SYBR\textsuperscript{\textregistered} Green PCR Master mix (Applied Biosystems). Primers were designed with the ABI PRISM Primer Express\textsuperscript{\textregistered} software; their sequences are presented in Table 1. For MCL and MM samples, RT-PCR amplifications were performed in a final volume of 15 µl containing PCR master mix, 5 ng of cDNA equivalents and primers (300 nM each for 18S rRNA, 400 nM for cyclin D1a and 800 nM for cyclin D1b). As negative control, real-time PCR was performed with purified non reverse-transcribed RNA of each sample. Expression of cyclin D1 isoforms compared to 18S rRNA was evaluated with the comparative threshold method (Ct). Each experiment was done in triplicate, triplicate values were averaged and averaged Ct values for 18S rRNA were subtracted from each value to give the \(\Delta\)Ct. U266 and JeKo-1 cells expressing high levels of both cyclin D1a and D1b mRNA were chosen as calibrators for MM and MCL cells, respectively. \(\Delta\)Ct obtained from U266 or JeKo-1 was subtracted from the \(\Delta\)Ct of each cell line to give \(\Delta\Delta\)Ct. The relative amount of each cyclin D1 isoform compared to the calibrator was calculated by the formula \(N = 2^{-\Delta\Delta\text{Ct}}\).

**Genomic DNA purification, cDNA synthesis and sequencing**

Genomic DNA of CD19+ MCL cells was isolated with the Wizard\textsuperscript{\textregistered} Genomic DNA (Promega). Total RNA was extracted from purified MCL cells and reverse-transcribed as before. Genomic DNA and cDNA were used as templates for PCR amplification using the Exon4 D1F and Intron4 D1R primers (see sequences in Table 1). PCR-amplified fragments encompassing the exon 4/intron 4 boundary were sequenced using the Big Dye Terminator

we found the co-expression of isoform b with from 8.8 to 12.9 (Table 2). In 9 out of 10 MCL patients, mRNA was detected in all MCL patients with 18S rRNA as internal standard. As expected, cyclin D1a expression of cyclin D1 transcripts was normalized to lin D1b allowing the comparison of their relative levels. Minimal deviation among duplicates or triplicates. The input amount of RNA (X-axis) vs. Ct values (Y-axis) with a linear correlation was confirmed by the plot of ΔCt values (Y-axis) with ΔCt ranging from 6.5–12.5, ΔCt 12.7–19.7. In only one tumor was a generous gift of Dr Alan J. Diehl. Reprobing blots with anti-β-tubulin Ab (sc-9104, Santa Cruz Biotech.) or anti-E2F1 (sc-251, Santa Cruz Biotech.) allowed us to check protein loading and transfer. Densitometric analyses were realized with a FluorImager using the Quantity-One software (Bio-Rad).

Results
Expression of cyclin D1 mRNA isoforms in MCL and MM patients and cell lines
Both spliced mRNAs have been detected by standard RT-PCR in MCL primary cells and MM cell lines [11]. To quantify the relative amounts of mRNA isoforms, primers specific for each isoform were designed and real-time quantitative RT-PCR was performed. The reliability of the method is illustrated in Figure 1. Total RNA purified from U266 cells was reverse-transcribed and serially diluted and samples were then amplified using the specific primers. A linear correlation was confirmed by the plot of input amount of RNA (X-axis) vs. Ct values (Y-axis) with minimal deviation among duplicates or triplicates. The efficacy of amplification was 100% for cyclin D1a and cyclin D1b allowing the comparison of their relative levels. The expression of cyclin D1 transcripts was normalized to 18S rRNA as internal standard. As expected, cyclin D1a mRNA was detected in all MCL patients with ΔCt varying from 8.8 to 12.9 (Table 2). In 9 out of 10 MCL patients, we found the co-expression of isoform b with ΔCt varying from 14.3 to 19.3. MCL patient 3 expressed only the isoform a. Cyclin D1a was predominant over cyclin D1b with a ratio R varying from 33 to 80 (Table 3). In MCL cell lines, isoform levels were almost in the same range than in primary cells (ΔCt 6.5–12.5, ΔCt 12.7–19.7). In only 3 out of 6 MM patients, total cyclin D1 was detected in CD138+ purified cells (data not shown); these three patients were studied further for cyclin D1 isoform expression. As expected, in MM primary cells and cell lines, cyclin D1a and b expression was highly heterogeneous (ΔCt 10.0–18.2, ΔCt 18.5–27.7) but perfectly correlated. They globally expressed less cyclin D1b mRNA than MCL (Table 2). The calculation of N illustrates the heterogeneity of cyclin D1a and b expression inside each series of samples (MM vs. MCL) and the heterogeneity of cyclin D1a vs. cyclin D1b expression for each case (see Additional file 2).

Expression, localization and stability of cyclin D1b protein in MCL samples
We detected the presence of both protein isoforms in MCL samples except for patient 3 (Figure 2A) and in cell lines (Figure 2B). The protein level of cyclin D1a (estimated by densitometric analysis) was higher than of form b (from 2 to 15-fold). In whole cell extracts, cyclin D1b was not detected in MM cell lines (data not shown), in good agreement with previous report [11]. Since cyclin D1 isoforms could display different sub-cellular localizations, nuclear and cytoplasmic protein extracts were prepared from MCL cell lines and primary cells and from MM cell lines, then immunoblotted. In MCL cell lines and primary cells, cyclin D1a (data not shown) and cyclin D1b localized both the nuclear and the cytoplasmic compartments with the exception of Pt 2 for which cyclin D1b was only nuclear (Figure 3). A very faint band was also visible in both extracts in NCI-H929 MM cells. Although not having the nuclear export signal, cyclin D1b displays the same sub-cellular distribution than cyclin D1a. GRANTA-519 and JeKo-1 cell lines were treated with cycloheximide to inhibit protein synthesis. We then monitored protein stability at the times indicated in the Figure 4. Cyclin D1b exhibited a half-life similar to cyclin D1a in both cell lines (indicated under each immunoblot). Both are short-lived proteins despite the absence of PEST sequences in isoform b.

Analysis of CCND1 polymorphism at position 9630 of genomic DNA and at position 870 of mRNA – Relation with the level of cyclin D1 forms a and b
CCND1 alternative splice could be modulated by a common G870A polymorphism within the splice donor site [4]. Moreover, AA genotype could be associated with a preferential expression of isoform b and a higher risk of cancers [12]. As presented in Table 3, MCL patient 5 was homozygous for the A allele, patient 6 homozygous for the G allele, the other 4 were heterozygous. Each tumor expressed either the A allele (3/6) or the G allele (3/6) but none expressed both alleles. Moreover, cyclin D1b was transcribed from the A or G allele and whatever the nucleotide at position 870, cyclin D1a was more expressed than cyclin D1b. The A/G genotype does not influence the relative level of the two transcripts.

Discussion
Using standard RT-PCR, we found previously that cyclin D1a and b were coexpressed in MCL patients and in MM cell lines irrespectively of the presence of the t(11;14) translocation [11]. We now extended this work and ana-
lyzed cyclin D1 isoform expression with a real-time quantitative RT-PCR in MM and MCL primary cells and cell lines.

Although cyclin D1 mRNA isoforms are always co-expressed in MCL and in cyclin D1-expressing MM cells, cyclin D1b protein was rarely and faintly expressed in MM
and MM samples. This sequence is present in both cyclin D1 isoforms. A sequence located in the NH2-terminal part of the protein binding to the anaphase-promoting complex and a RXXL response to stress, cyclin D1 can be degraded through another motif. In the case of cell which is peculiarly active in MCL [13] or cyclin D1 can be degraded through the proteasome machinery. Either the PEST sequence is not strictly necessary for proteolysis through the proteasome machinery similar to ours. Thus, endogenous and exogenous cyclin D1 isoforms are subjected to the same post-translational regulation. Whether the PEST sequence is not strictly necessary for proteolysis through the proteasome machinery similar to our results. Thus, the expression of cyclin D1b is not necessary at least for the maintenance of a tumoral phenotype. Interestingly, the presence of a short cyclin D1 transcript (1.7 kb) lacking the 3'UTR region responsible for mRNA stability, has been associated with MCL aggressiveness and a poor prognosis [1]. The relationship between the alternative spliced forms and the short mRNA has to be studied.

Cyclin D1b is rarely and faintly expressed in MM and not always detected in MCL ([17] and our results). Thus, the expression of cyclin D1b is not necessary at least for the maintenance of a tumoral phenotype. Interestingly, the presence of a short cyclin D1 transcript (1.7 kb) lacking the 3'-UTR region responsible for mRNA stability, has been associated with MCL aggressiveness and a poor prognosis [1]. The relationship between the alternative spliced forms and the short mRNA has to be studied.

In MCL, CCND1 alternative splicing does not modulate the level of transcripts b. This is consistent with results showing that CCND1 alternative splicing depends on sample origin [17]. Moreover, cyclin D1b is transcribed independently of A/G genotype. This indicates that both alleles can splice to form both transcripts. Besides A/G polymorphism, trans-elements regulate alternative splicing. In good agreement with us, Howe and Lynas also

The quantitation of cyclin D1a and cyclin D1b mRNA compared to 18S rRNA was done using the comparative Ct method with the ABI PRISM 7000 SDS software. Triplicate experiments were done for each sample; for each sample the average Ct value for the internal standard was subtracted from the average Ct value for cyclin D1a or cyclin D1b to yield ΔCta and ΔCtb. ΔCt obtained from the calibrator cell lines (JeKo-1 for MCL samples and U266 for MM samples) was subtracted from each ΔCta or ΔCtb to give the ΔΔCt. The relative amount of cyclin D1a and cyclin D1b compared to the calibrator was calculated by the formula R = 2-ΔΔCt obtained from the calibrator cell lines (JeKo-1 for MCL samples and U266 for MM samples) was subtracted from each ΔCta or ΔCtb to give the ΔΔCt. No cyclin D1b was detected in MCL patient 3 (Ctb>50); no cyclin D1a or b was detected in OPM-2 MM cell line (Cta>50 and Ctb>50). nc, not calculated; Pt, patient.

samples. By contrast, in MCL cells, cyclin D1b was often present. Thus, post-transcriptional mechanisms regulate cyclin D1b status depending on the B-cell hemopathy.

Cyclin D1a and D1b proteins exhibit the same stability. In previous studies [7,8], in transfected models, the calculated half-lives of cyclin D isoforms were also similar and similar to ours. Thus, endogenous and exogenous cyclin D1 isoforms are subjected to the same post-translational regulation. Either the PEST sequence is not strictly necessary for proteolysis through the proteasome machinery which is peculiarly active in MCL [13] or cyclin D1 can be degraded through another motif. In the case of cell response to stress, cyclin D1 can be degraded through its binding to the anaphase-promoting complex and a RXXL sequence located in the NH2-terminal part of the protein [14]. This sequence is present in both cyclin D1 isoforms.

### Table 3: CCND1 polymorphism, monoallelic transcription and cyclin D1 mRNA level

| MCL patient | Position 9630 | Position 870 | R* |
|-------------|---------------|--------------|----|

* R, the relative ratio of cyclin D1a mRNA vs. cyclin D1b mRNA was calculated with the formula R = 2-ΔΔCt obtained from the calibrator cell lines (JeKo-1 for MCL samples and U266 for MM samples) was subtracted from each ΔCta or ΔCtb to give the ΔΔCt. No cyclin D1b was detected in MCL patient 3 (Ctb>50); no cyclin D1a or b was detected in OPM-2 MM cell line (Cta>50 and Ctb>50). nc, not calculated; Pt, patient.

Genomic DNA and total RNA were extracted from CD19+ MCL cells and purified. RNA was reverse-transcribed and DNA samples were PCR-amplified before sequencing with Exon4 D1F and Intron4 D1R primers. Only the cyclin D1b mRNA form can be amplified with this couple of primers. GenBank of genomic DNA and at position 870 of cDNA (Genbank) indicate that the 3'-UTR region responsible for mRNA stability, has been associated with MCL aggressiveness and a poor prognosis [1]. The relationship between the alternative spliced forms and the short mRNA has to be studied.

Such a mechanism could be activated constitutively in MCL cells.

B-cell lymphomas can be induced in transgenic mice expressing a cyclin D1 mutant ([286A]) under the control of μ enhancer [15]. This mutant displays a 5-fold longer half-life than cyclin D1 [16] and is exclusively nuclear. This sub-cellular localization seems to be a prerequisite to transformation. In MCL cells, cyclin D1b localizes both the nuclear and cytoplasmic compartments. In good agreement, endogenous cyclin D1b appears cytoplasmic and nuclear in oesophageal carcinomas [7] In contrast, in transfected fibroblastic cells, cyclin D1b remains mostly nuclear [7-9]. The simplest explanation is that the nuclear export is subverted by an overexpression of exogenous cyclin D1b.

Cyclin D1b is rarely and faintly expressed in MM and not always detected in MCL ([17] and our results). Thus, the expression of cyclin D1b is not necessary at least for the maintenance of a tumoral phenotype. Interestingly, the presence of a short cyclin D1 transcript (1.7 kb) lacking the 3'-UTR region responsible for mRNA stability, has been associated with MCL aggressiveness and a poor prognosis [1]. The relationship between the alternative spliced forms and the short mRNA has to be studied.

Cyclin D1b is rarely and faintly expressed in MM and not always detected in MCL ([17] and our results). Thus, the expression of cyclin D1b is not necessary at least for the maintenance of a tumoral phenotype. Interestingly, the presence of a short cyclin D1 transcript (1.7 kb) lacking the 3'-UTR region responsible for mRNA stability, has been associated with MCL aggressiveness and a poor prognosis [1]. The relationship between the alternative spliced forms and the short mRNA has to be studied.

In MCL, CCND1 alternative splicing does not modulate the level of transcripts b. This is consistent with results showing that CCND1 alternative splicing depends on sample origin [17]. Moreover, cyclin D1b is transcribed independently of A/G genotype. This indicates that both alleles can splice to form both transcripts. Besides A/G polymorphism, trans-elements regulate alternative splicing. In good agreement with us, Howe and Lynas also
showed that CCND1 polymorphism does not affect the prognosis of MCL patients [18].

In breast, sarcoma and colon cancers, with cyclin D1 overexpression and no chromosome 11 alterations, elevated mRNA levels result from a trans-acting influence of both alleles [19]. A biallelic expression is seen in MM tumors without the t(11;14) [2]. In agreement with that observed in MM tumors with t(11;14), only one allele is transcribed in MCL cells, the transcribed allele is likely the structurally altered one.

**Conclusion**

Although cyclin D1b mRNA is produced in the vast majority of MM and MCL cells, cyclin D1b protein is not always found and not found exclusively in the nucleus. These data allowed us to conclude that a transforming activity of cyclin D1b over cyclin D1a is unlikely. Moreover, our data establish no relationship between A/G polymorphism and cyclin D1b expression. The relevance of cyclin D1b in MCL and MM pathologies remains elusive.
