2D Navier-Stokes equation with cylindrical fractional Brownian noise

Benedetta Ferrario, Christian Olivera

December 14, 2018

Abstract

We consider the Navier-Stokes equation on the 2D torus, with a stochastic forcing term which is a cylindrical fractional Wiener noise of Hurst parameter $H$. Following [8, 3] which dealt with the case $H = \frac{1}{2}$, we prove a local existence and uniqueness result when \( \frac{7}{16} < H < \frac{1}{2} \) and a global existence and uniqueness result when \( \frac{1}{2} < H < 1 \).

Key words and phrases. Stochastic partial differential equation, Navier-Stokes equations, cylindrical fractional Brownian motion.

MSC2010 subject classification: 60H15, 35R60, 60H30, 76D05.

1 Introduction

An incompressible fluid flow dynamics is described by the so-called incompressible Navier-Stokes equations. In this paper, we consider the Navier-Stokes equations on the torus, i.e. we work on the square $\mathbb{T} = [0, 2\pi]^2$ with periodic boundary conditions; we add a stochastic forcing term. These are the equations

\[
\begin{aligned}
\partial_t v &= \nu \Delta v - (v \cdot \nabla) v - \nabla p + \partial_t W^H \\
\text{div } v &= 0 \\
v|_{t=0} &= v_0
\end{aligned}
\]

(1.1)
where for \( t \in [0, T] \) and \( \xi \in \mathbb{T} \), \( v = v(t, \xi) \) is the vector velocity, \( p = p(t, \xi) \) the scalar pressure, \( \nu > 0 \) the viscosity coefficient and \( W^H = W^H(t, \xi) \) a cylindrical fractional Brownian process.

Stochastic perturbations in the equations of motions are commonly used to model small perturbations (numerical, empirical, and physical uncertainties) or thermodynamic fluctuations present in fluid flows. We refer to the lecture notes by Flandoli [14], the monograph of Kuksin and Shirikyan [17] as well as the references cited therein for a recent overview.

Different noise terms have been considered so far. The contribution of this paper is to study equation (2.2) with a cylindrical fractional Brownian motion \( W^H \) for \( H \neq \frac{1}{2} \). Indeed the case \( H = \frac{1}{2} \) has been studied in [1, 3, 8, 9]. Let us point out that with a coloured (not cylindrical) noise, the analysis of equations (1.1) is easier; some results on a more general bidimensional domain can be found in [12]. Moreover, the bigger is \( H \) the more regular is the fractional Brownian motion. Hence it is worth to ask if the cylindrical fractional Brownian motion with \( H < \frac{1}{2} \) can be considered; in addition also the analysis for \( H > \frac{1}{2} \) is interesting in order to compare the results for different values of the Hurst parameter. In this paper we shall prove local existence and uniqueness of solutions for \( \frac{7}{16} < H < \frac{1}{2} \) and global existence and uniqueness for \( \frac{1}{2} < H < 1 \).

As far as the contents of the paper are concerned, in Section 2 we introduce the mathematical setting, in Section 3 we analyze the linear Stokes problem, whereas Section 4 analyzes the bilinear term and Section 5 the Navier-Stokes problem. In the Appendices we present some proofs.

## 2 Mathematical setting

In this section we introduce the basic tools.

### 2.1 The spaces

For a complex number \( b = \Re b + i \Im b \) we denote by \( \overline{b} \) the complex conjugate \( \overline{b} = \Re b - i \Im b \) and by \( |b| \) the absolute value \( (|b| = \sqrt{(\Re b)^2 + (\Im b)^2}) \).

We consider subspaces of \( \mathbb{Z}^2 \):

\[
\mathbb{Z}_0^2 = \{ k = (k^{(1)}, k^{(2)}) \in \mathbb{Z}^2 : k \neq 0 \} \\
\mathbb{Z}_+^2 = \{ k = (k^{(1)}, k^{(2)}) \in \mathbb{Z}_0^2 : k^{(1)} > 0 \} \cup \{ k = (k^{(1)}, k^{(2)}) \in \mathbb{Z}_0^2 : k^{(1)} = 0, k^{(2)} > 0 \}
\]

and

\[
\mathbb{Z}_-^2 = \mathbb{Z}_0^2 \setminus \mathbb{Z}_+^2
\]
When \( k = (k^{(1)}, k^{(2)}) \in \mathbb{Z}^2 \), we denote by \(|k|\) the absolute value \(|k| = \sqrt{(k^{(1)})^2 + (k^{(2)})^2}\).

We consider the separable Hilbert space \( \mathcal{H}^0 \) which is the \( L^2 \)-closure of the space of smooth vectors which are periodic, zero mean value and divergence free. Let \( \{h_k\}_k \) be the basis for \( \mathcal{H}^0 \), given by

\[
h_k(\xi) = \frac{1}{2\pi} e^{i k \cdot \xi} \quad \text{for} \quad k \in \mathbb{Z}_0^2 \text{ and } \xi \in \mathbb{T}.
\]

Notice that, for any \( k \in \mathbb{Z}_0^2 \), \( h_{-k}(\xi) = -h_k(\xi) \) and \( \Delta h_k = -|k|^2 h_k \). Therefore

\[
\mathcal{H}^0 = \{ v(\xi) = \sum_{k \in \mathbb{Z}_0^2} v_k h_k(\xi) : v_{-k} = -v_k \quad \forall k, \quad \sum_{k \in \mathbb{Z}_0^2} |v_k|^2 < \infty \}.
\]

This is a Hilbert space with scalar product

\[
(u,v)_{\mathcal{H}^r} = \sum_{k \in \mathbb{Z}_0^2} |k|^{2r} u_k \overline{v_k}.
\]

Following [4], we define the periodic divergence-free vector Sobolev spaces \((r \in \mathbb{R}, 1 \leq p \leq \infty)\)

\[
\mathcal{H}_p^r = \{ v = \sum_{k \in \mathbb{Z}_0^2} v_k h_k : \sum_{k \in \mathbb{Z}_0^2} v_k |k|^r \in [L^p(\mathbb{T})]^2 \}
\]

and the periodic divergence-free vector Besov spaces as real interpolation spaces

\[
\mathcal{B}_{p,q}^r = (\mathcal{H}_{p}^{r_0}, \mathcal{H}_{p}^{r_1})_{\theta,q}, \quad r \in \mathbb{R}, 1 \leq p, q \leq \infty \quad r = (1-\theta)r_0 + \theta r_1, \quad 0 < \theta < 1
\]

In particular \( \mathcal{B}_{2,2}^r = \mathcal{H}_2^r = \mathcal{H}^r \). Moreover (see [4])

\[
\|v\|_{\mathcal{B}_{p,q}^{s_1}} \leq \|v\|_{\mathcal{B}_{p,q}^{s_2}} \quad \text{for } s_2 \leq s_1
\]

and

\[
\|v\|_{\mathcal{B}_{p,q}^{s_1}} \leq \|v\|_{\mathcal{B}_{p,q}^{s_2}} \quad \text{for } s_1 \leq s_2
\]

\[
\|v\|_{\mathcal{B}_{p,q}^{s_1}} \leq C\|v\|_{\mathcal{B}_{p,q}^{s_2}} \quad \text{for } s_1 - \frac{2}{p_1} = s_2 - \frac{2}{p_2}
\]
Here $C$ is a generic constant. We make the convention to denote different constants by the same symbol $C$, unless we want to mark them for further reference.

One interesting result in Besov spaces is given by the following estimate of Chemin (see Corollary 1.3.1 in [7]):

$$\|v_1 v_2\|_{B^{s_1+s_2}_{pq}} \leq \frac{C^{s_1+s_2}}{s_1 + s_2} \|v_1\|_{B^{s_1}_{pq}} \|v_2\|_{B^{s_2}_{pq}}$$  \hspace{1cm} (2.1)

if $s_1 + s_2 > 0$, $s_1 < \frac{2}{p}$, $s_2 < \frac{2}{p}$, $s = s_1 + s_2 - \frac{2}{p}$

and $p, q \in [1, \infty]$.

**2.2 The abstract equation**

Let us consider a unitary viscosity $\nu = 1$ in system (1.1). Then we write the evolution in abstract form as

$$dv(t) = Av(t) \ dt - B(v(t), v(t)) \ dt + dw^H(t)$$  \hspace{1cm} (2.2)

with the operators formally defined as $A = \Delta$ and $B(u, v) = P[(u \cdot \nabla)v]$, where $P$ is the projector operator onto the space of divergence free vector fields. We can represent the stochastic forcing term as

$$w^H(t, \xi) = \sum_{k \in \mathbb{Z}_2^+} h_k(\xi) b^H_k(t), \quad (t, \xi) \in \mathbb{R} \times \mathbb{T}$$  \hspace{1cm} (2.3)

where $\{b^H_k\}_{k \in \mathbb{Z}_2^+}$ is a sequence of i.i.d. complex fractional Brownian processes defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with filtration $\{\mathcal{F}_t\}_{t \in \mathbb{R}}$ and $b^H_{-k} = b^H_k$ for all $k \in \mathbb{Z}_2^+$. We denote by $\mathbb{E}$ the mathematical expectation with respect to $\mathbb{P}$. This means that $b^H_k(t) = \Re b^H_k(t) + i \Im b^H_k(t)$ and $\{\Re b^H_k, \Im b^H_k(t)\}_{k \in \mathbb{Z}_2^+}$ is a sequence of i.i.d. standard real fractional Brownian processes (fBm) with Hurst parameter $H$. Each element of the sequence is a centered Gaussian process whose covariance is

$$C(t, s) = \frac{1}{2}(|t|^{2H} + |s|^{2H} - |t - s|^{2H})$$

$w^H$ is called an $\mathcal{H}^0$-cylindrical fractional Brownian motion and one can prove that the series (2.3) converges in any space $U$ with continuous embedding $\mathcal{H}^0 \subset U$ of Hilbert-Schmidt type.
Now let us define rigorously the operators $A$ and $B$.

The Stokes operator $A$, as a linear operator in $B_{pq}^{s}$ with domain $B_{pq}^{s+2}$, generates an analytic semigroup $\{e^{tA}\}_{t\geq 0}$ in $B_{pq}^{s}$ and

$$
\|e^{tA}v\|_{B_{pq}^{s1}} \leq \frac{C}{t^{s_1-s_2}} \|v\|_{B_{pq}^{s2}}
$$

for any $t \geq 0$, $s_1 > s_2$.

As far as the bilinear term $B(u, v) = P[(u \cdot \nabla)v]$ is considered, we recall some basic properties (see [20]). Let $\langle \cdot, \cdot \rangle$ denote the $H^{-r} - H^r$ duality bracket. One checks by integrations by parts that

$$
\langle B(u_1, u_2), u_3 \rangle = -\langle B(u_1, u_3), u_2 \rangle
$$

(2.5)
and taking $u_2 = u_3$

$$
\langle B(u_1, u_2), u_2 \rangle = 0.
$$

(2.6)
These relationships are true with regular entries and then are extended to more general vectors by density.

A basic estimate is (see [15], Lemma 2.2)

$$
\|B(u, v)\|_{H^{-\delta}} \leq C \|u\|_{H^{\theta}} \|v\|_{H^{\rho}}
$$

(2.7)
when

$$
0 \leq \delta < 2, \quad \rho > 0, \quad \theta > 0
$$

$$
\rho + \delta > 1, \quad \theta + \rho + \delta \geq 2
$$

Other estimates have been given before in (2.1); indeed, by the divergence free condition we have $B(u, v) = P[\text{div} (u \otimes v)]$; therefore $\|B(u, v)\|_{S_{pq}^s} \leq \|u \otimes v\|_{S_{pq}^{s+1}}$.

Moreover, as done in [3], we can develop the bilinear term in Fourier series. Given $v = \sum_{l \in \mathbb{Z}_2^2} v_l h_l$ and $u = \sum_{h \in \mathbb{Z}_2^2} u_h h_h$, we have formally

$$
B(u, v) = iP \sum_{h \in \mathbb{Z}_2^2} u_h \sum_{l \in \mathbb{Z}_2^2} \frac{h^\perp \cdot l}{|l|} \frac{e^{ih \cdot \xi}}{2\pi} \frac{l^\perp}{|l|} \frac{e^{il \cdot \xi}}{2\pi}
$$

$$
= iP \sum_{k \in \mathbb{Z}_2^2} \left( \sum_{h \in \mathbb{Z}_2^2 \setminus \{k\}} \frac{2\pi}{|k-h|} u_h v_{k-h} (k-h)^\perp \right) \frac{e^{ik \cdot \xi}}{2\pi}.
$$
Using that the projector $P$ acts on the $k$-th component as $P_ka = \frac{a \cdot k^\perp}{|k|^2} k^\perp$, we get

$$B(u, v) = i \sum_{k \in \mathbb{Z}^2_0} \left( \sum_{h \in \mathbb{Z}^2_0 \setminus h \neq k} \frac{h^\perp \cdot k}{2\pi |h||k-h|} u_h v_{k-h} \frac{(k-h)^\perp \cdot k^\perp}{|k|} \right) k^\perp e^{ik \cdot \xi}$$

Summing up, the bilinear term can be written in Fourier series as

$$B(u, v) = \sum_{k \in \mathbb{Z}^2_0} B_k(u, v) h_k$$

(2.8)

with

$$B_k(u, v) = i \sum_{h \in \mathbb{Z}^2_0 \setminus h \neq k} \gamma_{h,k} u_h v_{k-h}$$

(2.9)

$$\gamma_{h,k} = \frac{1}{2\pi} \frac{(h^\perp \cdot k)([k-h] \cdot k)}{|h||k-h||k|}$$

Notice that $B_k = -B_{-k}$. The convergence of the series (2.8) will be analysed in the next section.

Our aim is to study equation (2.2) for $H \neq \frac{1}{2}$. Indeed the case $H = \frac{1}{2}$ has been studied in [1, 3, 8, 9]: Da Prato and Debussche proved the existence of a strong mild solution for $\mu$-a.e. initial condition (where $\mu$ is the Gibbs measure of the enstrophy, introduced in [2] which is an invariant measure for equation (2.2)), whereas Albeverio and Ferrario proved pathwise uniqueness of these solutions.

We shall prove a local existence and uniqueness result for $\frac{7}{16} < H < \frac{1}{2}$ and a global existence and uniqueness result for $H > \frac{1}{2}$. This latter result improves that of [12]; indeed, the case of cylindrical fBm is included in [12] but only for $H > \frac{1}{4}$ (see Theorem 5.1 and Corollary 4.3 there). By the way, there are other differences with respect to [12]: in [12] the spatial domain is not the torus but a generic smooth bounded subset $D$ of $\mathbb{R}^2$ (and the Dirichlet boundary condition is assumed) and the solution is a process with values in $L^4$ in time and space, whereas our solution is more regular since a.a. paths are at least in $C([0, T]; H^{\frac{1}{2}})$ (see next Theorem 5.9 with $H > \frac{3}{4}$) and one knows that $H^{\frac{1}{2}} \subset L^4(D)$.

In order to analyze equation (2.2) we introduce as in [8] two subproblems: the linear Stokes equation

$$dz(t) = Az(t) \ dt + dw^H(t)$$

6
and the equation for $u = v - z$

$$\frac{du}{dt}(t) = Au(t) - B(u(t), u(t)) - B(u(t), z(t)) - B(z(t), u(t)) - B(z(t), z(t))$$

which is a Navier-Stokes type equation with random coefficients.

First we deal with the linear problem for $z$, then we define the bilinear term $B(z, z)$ a.s. as in [8, 3] and finally face the nonlinear equation for $u$. At the end we recover the existence result for $v$ from the representation $v = z + u$.

### 3 The Stokes equation

If we neglect the bilinear term in (2.2), we obtain the linear Stokes equation

$$dv(t) = Av(t) \, dt + dw^H(t).$$

We consider its stationary mild solution; this is the process

$$z(t) = \int_{-\infty}^{t} e^{(t-s)A} dw^H(s)$$

We can write

$$z(t)(\xi) = \sum_{k \in \mathbb{Z}^2_0} h_k(\xi) \int_{-\infty}^{t} e^{-|k|^2(t-s)} db^H_k(s)$$

$$= 2 \sum_{k \in \mathbb{Z}^2_0} \frac{k \perp 2\pi|k|}{2\pi} \cos(k \cdot \xi) \int_{-\infty}^{t} e^{-|k|^2(t-s)} d\Re b^H_k(s)$$

$$- 2 \sum_{k \in \mathbb{Z}^2_0} \frac{k \perp 2\pi|k|}{2\pi} \sin(k \cdot \xi) \int_{-\infty}^{t} e^{-|k|^2(t-s)} d\Im b^H_k(s)$$

First, we provide a result for each stochastic convolution integral appearing in the Fourier series representation.

**Lemma 3.1.** Let $\lambda > 0$ and $b^H$ be a real fBm of Hurst parameter $H \in (0, 1)$. Then

$$\int_{-\infty}^{t} e^{-\lambda(t-s)} db^H(s), \quad t \in \mathbb{R}$$

is a stationary centered Gaussian process whose variance is

$$C_H \lambda^{-2H}$$

where $C_H$ is the positive constant given in (3.4).
Proof. Following the proof of Lemma 4.1 in [12] we have that the random variables
\[
\int_{-\infty}^{t} e^{-\lambda(t-s)} db^H(s)
\]
and
\[
\int_{0}^{+\infty} e^{-\lambda r} db^H (r)
\]
have the same law. Moreover, by self-similarity of the fBm, the latter random variable has the same law as
\[
\lambda^{-H} \int_{0}^{+\infty} e^{-r} db^H (r).
\]
Therefore
\[
E \left( \int_{-\infty}^{t} e^{-\lambda(t-s)} db^H(s) \right)^2 = \lambda^{-2H} E \left( \int_{0}^{+\infty} e^{-r} db^H (r) \right)^2
\]
We estimate \( E \left( \int_{0}^{+\infty} e^{-r} db^H (r) \right)^2 \) using the representation
\[
\int_{0}^{+\infty} e^{-r} db^H(r) = \int_{0}^{+\infty} e^{-r} b^H (r) dr.
\]
This comes from the formula on a finite time interval
\[
\int_{0}^{T} e^{-r} db^H(r) = e^{-T} b^H (T) + \int_{0}^{T} e^{-r} b^H(r) dr
\]
and the fact that by the law of iterated logarithm (see [5]) we get
\[
\lim_{T \to +\infty} |e^{-T} b^H (T)| = 0 \quad \mathbb{P} - a.s.
\]
Hence
\[
E \left( \int_{0}^{+\infty} e^{-r} db^H (r) \right)^2 = E \left( \int_{0}^{+\infty} e^{-r} b^H (r) dr \right)^2
\]
\[
= \int_{0}^{+\infty} \int_{0}^{+\infty} e^{-r} e^{-s} r^{2H} + s^{2H} - |r-s|^{2H} \frac{2}{2} dr ds
\]
By elementary calculations one shows that the latter integral is finite. We set
\[
C_H = \int_{0}^{+\infty} \int_{0}^{+\infty} e^{-r} e^{-s} r^{2H} + s^{2H} - |r-s|^{2H} \frac{2}{2} dr ds. \quad (3.4)
\]
Now we come back to the stationary process \( z \) given in (3.2). We have the following result
Proposition 3.2. For any $r < 2(H - \frac{1}{2})$ we have
\[ z \in C(\mathbb{R}; \mathcal{H}^r) \quad \mathbb{P} - a.s. \]

Proof. First we show that for any fixed time, the random variable $z(t) \in \mathcal{H}^r$, $\mathbb{P}$-a.s. Indeed, using (3.3) and the previous Lemma we have
\[
\mathbb{E}[\|z(t)\|_{\mathcal{H}^r}^2] = \sum_{k \in \mathbb{Z}^2_0} |k|^{2r} \left| \int_{-\infty}^t e^{-|k|^2(t-s)} dB_k^H(s) \right|^2 = \sum_{k \in \mathbb{Z}^2_0} |k|^{2r} \frac{C_H}{|k|^{4H}}
\]
The latter series is convergent for $4H - 2r > 2$, i.e. $r < 2(H - \frac{1}{2})$.

It follows that for any finite $m \geq 1$ we have $z \in L^m_{\text{loc}}(\mathbb{R}; \mathcal{H}^r)$, $\mathbb{P}$-a.s.. Indeed, $z(t)$ is a Gaussian random variable; so all the moments are finite, i.e. for any $m \geq 2$ there exists a finite constant $e_m$ such that
\[
\mathbb{E}[\|z(t)\|_{\mathcal{H}^r}^m] = e_m
\]
for any $t$. Moreover, the process $z$ is a stationary process and by interchanging the integrals, for any $T_1 < T_2$ we get
\[
\mathbb{E}\left[ \int_{T_0}^{T_1} \|z(t)\|_{\mathcal{H}^r}^m dt \right] = \int_{T_0}^{T_1} \mathbb{E}[\|z(t)\|_{\mathcal{H}^r}^m] dt = e_m(T_1 - T_0) < \infty
\]
Since the expectation is finite, then $\int_{T_0}^{T_1} \|z(t)\|_{\mathcal{H}^r}^m dt < \infty$, $\mathbb{P}$-a.s.

The continuity in time of the trajectories has been proved in [11] when $H > \frac{1}{2}$ and in [19] when $H < \frac{1}{2}$.

Remark 3.3. We see that when $H \leq \frac{1}{2}$, the process $z$ at any fixed time takes values in a distributional space. This is the source of the difficulty in our problem.

Remark 3.4. From the proof of Proposition 3.2, we obtain that the process $z$ is a stationary process and for any time $t$ the law of $z(t)$ is the centered Gaussian measure $\mu^H \sim \mathcal{N}(0, C_H(-A)^{-2H})$. More precisely, we assign the measure $\mu^H$ on the sequences \( \{ (\Re v_k, \Im v_k) \}_{k \in \mathbb{Z}_+^2} \) as
\[
\mu^H = \otimes_{k \in \mathbb{Z}_+^2} \mu^H_k \tag{3.5}
\]
with
\[
d\mu^H_k(x, y) = \frac{|k|^{4H}}{2\pi C_H} e^{-\frac{|k|^{2H}}{2C_H} (x^2 + y^2)} \, dx \, dy
\]
When we identify the space $\mathcal{H}^r$ with that of the sequences $\{(\Re v_k, \Im v_k)\}_{k \in \mathbb{Z}^d}$ such that $\sum_{k \in \mathbb{Z}^d} |k|^2 r (|\Re v_k|^2 + |\Im v_k|^2) < \infty$, we get $\mu^H(\mathcal{H}^r) = 1$ for any $r < 2(H - \frac{1}{2})$ and $\mu^H(\mathcal{H}^r) = 0$ for any $r \geq 2(H - \frac{1}{2})$ (see [10]). Similarly, $\mu^H(\mathcal{B}^r_{pq}) = 1$ for any $r < 2(H - \frac{1}{2})$ and $\mu^H(\mathcal{B}^r_{pq}) = 0$ for any $r \geq 2(H - \frac{1}{2})$.

We finish this section with a result on the deterministic Stokes equation, that will be used in the sequel. Given the deterministic linear problem

\[
\begin{cases}
\frac{dx}{dt}(t) = Ax(t) + f(t), & t \in (0, T] \\
x(0) = x_0
\end{cases}
\]

we represent its mild solution as

\[x(t) = e^{tA}x_0 + \int_0^t e^{(t-s)A}f(s) \, ds\]

and we have (see [6] Proposition 4.1, based on [10])

**Proposition 3.5.** Let $1 < p, q, r < \infty$ and $s \in \mathbb{R}$.

For any $f \in L^r(0, T; \mathcal{B}^s_{pq})$ and $x_0 \in \mathcal{B}^{s+2^{\frac{2}{r}}}_{pr}$, there exists a unique solution $x \in W^{1,r}(0, T) \equiv \{ x \in L^r(0, T; \mathcal{B}^{s+2^{\frac{2}{r}}}_{pq}) : \frac{dx}{dt} \in L^r(0, T; \mathcal{B}^s_{pq}) \}$.

Moreover, the functions $x, \frac{dx}{dt}$ depend continuously on the data $f$ and $x_0$, that is there exists a positive constant $C$ such that

\[\left( \int_0^T (\|x(t)\|^{r}_{\mathcal{B}^{s+2^{\frac{2}{r}}}_{pq}} + \|\frac{dx}{dt}(t)\|^{r}_{\mathcal{B}^{s}_{pq}}) \, dt \right)^{1/r} \leq \left( C \int_0^T \|f(t)\|^{r}_{\mathcal{B}^{s}_{pq}} \, dt \right)^{1/r} + \|x_0\|_{\mathcal{B}^{s+2^{\frac{2}{r}}}_{pr}}\]

Finally, the space $W^{1,r}(0, T)$ is continuously embedded into the space $C([0, T]; \mathcal{B}^{s+2^{\frac{2}{r}}}_{pr})$, that is there exists a positive constant $C$ such that

\[\|x\|_{C([0, T]; \mathcal{B}^{s+2^{\frac{2}{r}}}_{pr})} \leq C \|x\|_{W^{1,r}(0, T)} \quad \text{for} \quad r < 2(H - \frac{1}{2})
\]

and therefore the initial condition makes sense.

All the constants depend only on $p, q, r, s$.

4 The bilinear term

When we study equation for the auxiliary process $u = v - z$, there appears $B(z, z)$. We analyse the space regularity of this term. Following [2, 11, 8, 3], we estimate it with respect to the Gaussian measure $\mu^H$. 

Proposition 4.1. Let $\frac{1}{4} < H < 1$ and

\[
\begin{align*}
\rho < 4H - 3 & \quad \text{if } \frac{1}{4} < H < \frac{1}{2} \\
\rho < 2(H - 1) & \quad \text{if } \frac{1}{2} \leq H < 1
\end{align*}
\] (4.1) (4.2)

Then, for any $m \in \mathbb{N}$

\[
\int \|B(z, z)\|_{H^\rho}^{2m} \mu^H(dz) < \infty.
\] (4.3)

Proof. Let us begin to perform computations for $m = 1$.

First, we explain why we need the lower bound $H > \frac{1}{4}$. By (2.9) we have

\[
\int \|B(z, z)\|_{H^\rho}^{2} \mu^H(dz) = \sum_{k \in \mathbb{Z}_0^2} |k|^{2\rho} \left( \int |B_k(z, z)|^2 \mu^H(dz) \right)
\] (4.4)

From (2.9) we have that $\gamma_{h,k} = \gamma_{k-h,k}$ and $\gamma_{h,k}^2 \leq |k|^2$; then we can bound

\[
\int \|B(z, z)\|_{H^\rho}^{2} \mu^H(dz) \text{ by}
\] (4.5)

For any fixed $k$, the latter series (over $h$) is convergent if and only if $8H > 2$. Therefore we require

\[
H > \frac{1}{4}.
\]

The inner series depends on $k$ as proved in Lemma [A.1] in the Appendix.
Therefore the double series \((4.5)\) is estimated by:

\[
\begin{aligned}
&\sum_{|k| \geq 2} |k|^{2\rho + 2} & \left( \frac{1}{|k|^{8H-2}} \right) & \text{if } \frac{1}{4} < H < \frac{1}{2} \\
&\sum_{|k| \geq 2} |k|^{2\rho + 2} \ln |k| & \left( \frac{1}{|k|^2} \right) & \text{if } H = \frac{1}{2} \\
&\sum_{|k| \geq 2} |k|^{2\rho + 2} & \left( \frac{1}{|k|^{4H}} \right) & \text{if } H > \frac{1}{2}
\end{aligned}
\]

The first series converges when \(\rho < 4H - 3\), the second one when \(\rho < -1\) and the third one when \(\rho < 2H - 2\). This provides the summability \((4.3)\) under conditions \((4.1)-(4.2)\).

Now, let us consider higher powers \(m > 1\). We have that \((4.3)\) holds also for the other powers, since \(\mu^H\) is Gaussian and therefore the higher moments are expressed by means of the second moments. For completeness we provide computations for \(m = 2\) in Appendix B.

Using the stationarity we can write \((4.3)\) also as:

\[
E \left[ \|B(z(t), z(t))\|_{H^\rho}^{2m} \right] =: e_m < \infty
\]

for an \(t \in \mathbb{R}\). As an easy consequence, we obtain:

\[
E \left[ \int_{t_0}^{t_1} \|B(z(t), z(t))\|_{H^\rho}^{2m} dt \right] = (t_1 - t_0) \int \|B(z, z)\|_{H^\rho}^{2m} \mu^H (dz) < \infty
\]

for any \(\infty < t_0 < t_1 < \infty\). Hence

**Corollary 4.2.** Let \(m \geq 1\) and \(T > 0\). Choosing \(\rho\) as in \((4.1)-(4.2)\) we get:

\[
B(z, z) \in L^m(0, T; H^\rho)
\]

\(\mathbb{P}\)-a.s.

**Remark 4.3.** Notice that for \(\frac{1}{2} < H < 1\) the quadratic term \(B(z, z)\) is in \(L^2(0, T; H^{-1})\), \(\mathbb{P}\)-a.s.

# 5 The nonlinear auxiliary equation

Let \(v\) be the unknown for our equation \((2.2)\) and let \(z\) be the stationary Stokes process given by \((3.2)\). The process \(u = v - z\) solves the equation

\[
\frac{du}{dt} = Au - B(u, u) - B(u, z) - B(z, u) - B(z, z).
\]

\((5.1)\)
For \( r < 2(H - \frac{1}{2}) \) we have \( z(0) \in B^r_{pq}, \) \( \mathbb{P} \)-a.s. and we take \( u(0) = v(0) - z(0). \)

We shall prove that equation (5.1) has a local solution when \( \frac{7}{10} < H < \frac{1}{2} \) whereas we have a global result when \( \frac{1}{2} < H < 1. \) This implies results for the unknown \( v = z + u. \)

**5.1 \( \frac{1}{4} < H < \frac{1}{2} \)**

We consider a mild solution \( u \) to equation (5.1). We want to show local existence (and uniqueness) by means of a fixed point argument. Thus we define the mapping \( I \)

\[
[I(u)](t) = e^{tA}u(0) - \int_0^t e^{(t-s)A}B(u(s), u(s)) \, ds - \int_0^t e^{(t-s)A}B(z(s), u(s)) \, ds \\
- \int_0^t e^{(t-s)A}B(u(s), z(s)) \, ds - \int_0^t e^{(t-s)A}B(z(s), z(s)) \, ds
\] (5.2)

A fixed point of \( I \) is a mild solution of equation (5.1).

Given \( T > 0, \) let

\[
\mathcal{E}_T = L^\beta(0, T; B^\alpha_{pq}) \cap C([0, T]; B^\sigma_{pq}).
\]

First, we want to show that \( I : \mathcal{E}_T \to \mathcal{E}_T \) for suitable values of the parameters \( \alpha, \beta, \sigma, p, q, H. \)

Define

\[
I_0(t) = e^{tA}u_0.
\]

Given \( u_0 \in B^\sigma_{pq}, \) it is an easy result that \( I_0 \in \mathcal{E}_T \) when

\[
\alpha < \sigma + \frac{2}{\beta}.
\]

Indeed, \( \|e^{tA}u_0\|_{B^\sigma_{pq}} \leq \|u_0\|_{B^\sigma_{pq}}; \) by (2.4) we have

\[
\int_0^T \|e^{tA}u_0\|_{B^\sigma_{pq}}^\beta \, dt \leq C \int_0^T \frac{dt}{t^{\alpha+\frac{2}{\beta}}}
\]

and the latter integral is finite when \( \alpha < \sigma + \frac{2}{\beta}. \)

To study the integrals involving \( B(u, u), B(z, u) \) and \( B(u, z) \) we define

\[
I_1(u, \tilde{u})(t) = \int_0^t e^{(t-s)A}B(u(s), \tilde{u}(s)) \, ds.
\]
Lemma 5.1. Let $\alpha, \sigma \in \mathbb{R}$ and $\beta, p, q \geq 1$ be such that
\[
\begin{cases}
\frac{2}{p} + \frac{2}{\beta} < \sigma + 1 \\
\alpha < \frac{2}{p}, \quad \sigma < \frac{2}{p} \\
\alpha + \sigma > 0
\end{cases}
\]
If $u \in L^\beta(0,T;B^\alpha_{pq})$ and $\tilde{u} \in C([0,T];B^\sigma_{pq})$, then
\[
\|I_1(u, \tilde{u})\|_{L^\beta(0,T;B^\alpha_{pq})} \leq CT^\frac{1}{2} - \frac{1}{p} + \frac{2}{\beta} \|u\|_{L^\beta(0,T;B^\alpha_{pq})} \|\tilde{u}\|_{C([0,T];B^\sigma_{pq})}
\]
and
\[
\|I_1(\tilde{u}, u)\|_{L^\beta(0,T;B^\alpha_{pq})} \leq CT^\frac{1}{2} - \frac{1}{p} + \frac{2}{\beta} \|u\|_{L^\beta(0,T;B^\alpha_{pq})} \|\tilde{u}\|_{C([0,T];B^\sigma_{pq})}
\]
where the constant $C$ is independent of the time $T$.

Proof. We consider the first estimate, since the second one is obtained in the same way interchanging $u$ and $\tilde{u}$.

We use (2.1) with $s_1 = \alpha$ and $s_2 = \sigma$:
\[
\|B(u, \tilde{u})\|_{B^{\alpha+\sigma-\frac{2}{p}-1}_{pq}} \leq C\|u\|_{B^\alpha_{pq}} \|\tilde{u}\|_{B^\sigma_{pq}}
\]
where $\alpha < \frac{2}{p}$, $\sigma < \frac{2}{p}$ and $\alpha + \sigma > 0$. Then we get that $B(u, \tilde{u}) \in L^\beta(0,T;B^{\alpha+\sigma-\frac{2}{p}-1}_{pq})$.

Moreover
\[
\|I_1(u, \tilde{u})\|_{L^\beta(0,T;B^\alpha_{pq})} \leq \int_0^T \left( \int_0^t \|e^{(t-s)A}B(u(s), \tilde{u}(s))\|_{B^\alpha_{pq}} ds \right)^{\beta} dt.
\]
Now, we perform estimates using (2.4) and the Hölder inequality:
\[
\int_0^t \|e^{(t-s)A}B(u(s), \tilde{u}(s))\|_{B^\alpha_{pq}} ds
\leq \int_0^t \frac{C}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{2}{\beta}}} \|B(u(s), \tilde{u}(s))\|_{B^{\alpha+\sigma-\frac{2}{p}-1}_{pq}} ds
\leq C \int_0^t \frac{1}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{2}{\beta}}} \|u(s)\|_{B^\alpha_{pq}} \|\tilde{u}(s)\|_{B^\sigma_{pq}} ds
\leq C\|\tilde{u}\|_{C([0,T];B^\sigma_{pq})} \left( \int_0^t \frac{ds}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{2}{\beta}} \frac{1}{\beta}} \right)^{1-\frac{1}{\beta}} \left( \int_0^t \|u(s)\|_{B^\alpha_{pq}} ds \right)^{\frac{1}{\beta}}
\leq CT^\frac{1}{2} - \frac{1}{p} + \frac{2}{\beta} \|\tilde{u}\|_{C([0,T];B^\sigma_{pq})} \|u\|_{L^\beta(0,T;B^\alpha_{pq})}
\]
Integrating in time over the interval $[0, T]$, we conclude the proof. \hfill \Box

Now we consider the other norm for $I_1$.

**Lemma 5.2.** Let $\alpha, \sigma \in \mathbb{R}$ and $\beta, p, q \geq 1$ be such that

$$
\begin{aligned}
\frac{2}{p} + \frac{2}{q} &< \alpha + 1 \\
\beta &\geq q \\
\alpha &< \frac{2}{p}, \quad \sigma < \frac{2}{p} \\
\alpha + \sigma &> 0
\end{aligned}
$$

If $u \in L^\beta(0, T; B^\alpha_{pq})$ and $\tilde{u} \in C([0, T]; B^\sigma_{pq})$, then

$$
\| I_1(u, \tilde{u}) \|_{C([0,T]; B^\sigma_{pq})} \leq CT^{\frac{\beta}{2} + \frac{1}{2} - \frac{1}{p}} \| u \|_{L^\beta(0,T; B^\alpha_{pq})} \| \tilde{u} \|_{C([0,T]; B^\sigma_{pq})}
$$

and

$$
\| I_1(\tilde{u}, u) \|_{C([0,T]; B^\sigma_{pq})} \leq CT^{\frac{\beta}{2} + \frac{1}{2} - \frac{1}{p}} \| u \|_{L^\beta(0,T; B^\alpha_{pq})} \| \tilde{u} \|_{C([0,T]; B^\sigma_{pq})}
$$

where the constant $C$ is independent of the time $T$.

**Proof.** First, from the previous proof we know that $B(u, \tilde{u}) \in L^\beta(0, T; B^{\alpha+\sigma-\frac{2}{p}-1}_{pq})$; when $\beta \geq q$ we also have $B(u, \tilde{u}) \in L^q(0, T; B^{\alpha+\sigma-\frac{2}{p}-1}_{pq})$ and Proposition 3.5 provides $I_1(u, \tilde{u}) \in C([0, T]; B^{\alpha+\sigma-\frac{2}{p}+1-\frac{1}{q}-\frac{1}{2}}_{pq})$ and finally we use that $B^{\alpha+\sigma-\frac{2}{p}+1-\frac{1}{q}-\frac{1}{2}}_{pq}$ when $\frac{2}{p} + \frac{2}{q} \leq \alpha + 1$.

Now, we perform estimates using (2.4) and the Hölder inequality.

$$
\| I_1(u, \tilde{u})(t) \|_{B^\sigma_{pq}} \leq \int_0^t || e^{(t-s)A} B(u(s), \tilde{u}(s)) ||_{B^\sigma_{pq}} ds
$$

\begin{align*}
&\leq \int_0^t \frac{C}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{\alpha}{2}}} || B(u(s), \tilde{u}(s)) ||_{B^{\alpha+\sigma-\frac{2}{p}-1}_{pq}} ds \\
&\leq \int_0^t \frac{C}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{\alpha}{2}}} || u(s) ||_{B^\alpha_{pq}} || \tilde{u}(s) ||_{B^\sigma_{pq}} ds \\
&\leq || \tilde{u} ||_{C([0,T]; B^\sigma_{pq})} \int_0^t \frac{C}{(t-s)^{\frac{1}{2} + \frac{1}{p} - \frac{\alpha}{2}}} || u(s) ||_{B^\alpha_{pq}} ds \\
&\leq C || \tilde{u} ||_{C([0,T]; B^\sigma_{pq})} || u ||_{L^\beta(0,T; B^\alpha_{pq})} \left( \int_0^t \frac{ds}{(t-s)^{\frac{\beta}{\beta-1} \left( \frac{1}{2} + \frac{1}{p} - \frac{\alpha}{2} \right)}} \right)^{1-\frac{1}{p}}
\end{align*}
The latter integral is finite when \( \left( \frac{2}{\beta^2 - 1} \right) \left( \frac{1}{2} + \frac{1}{p} - \frac{q}{2} \right) < 1 \), i.e.

\[
\frac{2}{\beta} + \frac{2}{p} < \alpha + 1 \tag{5.3}
\]

This inequality is true when \( \beta \geq q \) and \( \frac{2}{q} + \frac{2}{p} < \alpha + 1 \), that is our assumptions imply (5.3).

Computing the time interval and taking the supremum over \( t \in [0, T] \) we get the required estimate.

For the integral involving \( B(z, z) \) we define the process

\[
I_2(t) = \int_0^t e^{(t-s)A} B(z(s), z(s)) ds, \quad t \geq 0
\]

where \( z \) is the Stokes process given in (3.2).

**Lemma 5.3.** Let \( \frac{1}{4} < H < \frac{1}{2}, \beta, p \geq 1, q \geq 2 \) and \( \alpha, \sigma \in \mathbb{R} \) be such that

\[
\alpha \leq \sigma + 1, \quad \sigma < 4H - 2.
\]

Then \( I_2 \in \mathcal{E}_T, \mathbb{P}\text{-a.s.} \).

**Proof.** We proceed pathwise. First we show that \( I_2 \in L^\beta(0, T; B_{pq}^\alpha) \). From Corollary 4.2 we know that the paths of \( B(z, z) \) are in \( L^\beta(0, T; B_{pq}^{\sigma - 1}) \) for any \( \beta \geq 1 \) and for \( \sigma < 4H - 2 \). Therefore, according to Proposition 3.5 the paths of \( I_2 \) are in \( L^\beta(0, T; B_{pq}^{\sigma + 1}) \). When \( \alpha \leq \sigma + 1 \), the embedding theorem gives \( I_2 \in L^\beta(0, T; B_{pq}^{\alpha}) \).

Now, we show that \( I_2 \in C([0, T]; B_{pq}^\alpha) \). Again by Corollary 4.2 for any \( q \geq 1 \) and \( \sigma < 4H - 2 \) the paths of \( B(z, z) \) are in \( L^q(0, T; B_{pq}^{\sigma - 1}) \). We bear in mind Proposition 3.5 and we get that \( I_2 \in C([0, T]; B_{pq}^{\sigma + 1 - \frac{2}{q}}) \). When \( q \geq 2 \) this finishes the proof.

Summing up, we have proved estimates for all the terms in the r.h.s. of (5.2). Let us point out that merging these results we have to satisfy two conditions:

\[
\sigma < 2(H - \frac{1}{2})
\]

which comes from Proposition 3.2 and provides \( z \in C([0, T]; H^\sigma), \mathbb{P}\text{-a.s.} \), so to apply Lemma 5.1 and 5.2 for the integrals involving \( B(z, u) \) and \( B(u, z) \), and

\[
\sigma < 4H - 2
\]

which comes from Lemma 5.3 to estimate the integral involving \( B(z, z) \).

When \( H < \frac{1}{2} \), the latter condition is stronger and we will write only this one in the following.
Proposition 5.4. Let $\frac{1}{4} < H < \frac{1}{2}$, $\alpha, \sigma \in \mathbb{R}$, $\beta, p \geq 1$ and $q \geq 2$ be such that

\begin{align*}
\frac{2}{p} + \frac{2}{\beta} &< \sigma + 1 & (5.4) \\
\frac{2}{p} + \frac{2}{q} &< \alpha + 1 & (5.5) \\
\beta &\geq q & (5.6) \\
\alpha &\leq \frac{2}{p} & (5.7) \\
\sigma &\geq \frac{2}{p} & (5.8) \\
\alpha + \sigma &> 0 & (5.9) \\
\alpha &< \sigma + \frac{2}{\beta} & (5.10) \\
\alpha &\leq \sigma + 1 & (5.11) \\
\sigma &< 4(H - \frac{1}{2}) & (5.12)
\end{align*}

Then, for any finite $T$ we have that $I : \mathcal{E}_T \to \mathcal{E}_T$, $\mathbb{P}$-a.s..

Remark 5.5 (How to fulfill conditions). Notice that by condition (5.12) we have $\sigma < 0$ when $H < \frac{1}{2}$. Therefore, condition (5.9) requires $\alpha > 0$.

Moreover, conditions (5.9) and (5.11) provide

\[-\sigma < \alpha \leq \sigma + 1;
\]

thus it is necessary that $\sigma > -\frac{1}{2}$, i.e. $H > \frac{3}{8}$.

Actually we are going to show that $H$ must be bigger than $\frac{3}{8}$ in order to satisfy all the conditions (5.4) - (5.12). Indeed, we write a system equivalent to the previous one. Condition (5.8) is trivially satisfied when $\sigma < 0$ and can be neglected. Taking $\beta = q$, condition (5.5) is weaker than condition (5.4), that is (5.4) implies (5.5). In addition, since condition (5.4) requires $\frac{2}{\beta} < 1$, we have that condition (5.11) is weaker than condition (5.10), that is (5.10) implies (5.11). Therefore, in the case $\beta = q$ the previous system of
conditions is equivalent to
\[
\frac{2}{p} + \frac{2}{\beta} < \sigma + 1 \quad (5.4)
\]
\[
\beta = q \quad (5.6)
\]
\[
\alpha < \frac{2}{p} \quad (5.7)
\]
\[
\alpha + \sigma > 0 \quad (5.9)
\]
\[
\alpha < \frac{\sigma}{\beta} + 2 \quad (5.10)
\]
\[
\sigma < 4(H - \frac{1}{2}) \quad (5.12)
\]
which is simpler to analyse. Let us notice that
\[
-3\sigma < \alpha + \alpha - \sigma < \frac{2}{p} + \frac{2}{\beta} < \sigma + 1
\]
by (5.9) and (5.10).

This sequence of inequalities is meaningful only when \(-3\sigma < \sigma + 1\), i.e. \(\sigma > -\frac{1}{4}\). Taking into account the last condition (5.12), we see that in order to fulfil all the above conditions it is necessary that \(H > \frac{9}{16}\).

Therefore it is possible to fulfil all the conditions when \(\frac{7}{16} < H < \frac{1}{2}\).

Setting \(H = \frac{7}{16} + c\) with \(0 < c < \frac{1}{16}\), we can choose for instance
\[
\alpha = \frac{1}{4} - 2c, \quad \sigma = -\frac{1}{4} + 3c, \quad \frac{2}{\beta} = \frac{2}{q} = \frac{1}{2} - 4c, \quad \frac{2}{p} = \frac{1}{4} - c
\]
in order to satisfy (5.4) – (5.12).

Now we can prove the local existence result for \(u\), proving that \(I\) is a contraction for \(T\) small enough.

**Proposition 5.6.** Let \(\frac{7}{16} < H < \frac{1}{2}\) and the parameters fulfil the conditions (5.4) – (5.12). Then, given \(u_0 \in \mathcal{B}_{pq}^{\alpha}\) there exist a stopping time \(\tau \in [0, T]\) and for \(\mathbb{P}\)-a.e. \(\omega\) a unique mild solution \(u(\omega, \cdot)\) of equation (5.1) with values in \(C([0, \tau(\omega)]; \mathcal{B}_{pq}^{\alpha}) \cap L^\beta(0, \tau(\omega); \mathcal{B}_{pq}^{\alpha})\).
Proof. Using the bilinearity of the operator $B$, we get

$$I(u_1(t)) - I(u_2(t)) = -\int_0^t e^{(t-s)A}B(u_1(s), u_1(s) - u_2(s))ds$$
$$- \int_0^t e^{(t-s)A}B(u_1(s) - u_2(s), u_2(s))ds$$
$$- \int_0^t e^{(t-s)A}B(z(s), u_1(s) - u_2(s))ds$$
$$- \int_0^t e^{(t-s)A}B(u_1(s) - u_2(s), z(s))ds$$

Let us work in the subspace of $\mathcal{E}_T$ with $\|u\|_{\mathcal{E}_T} \leq M$. The initial data $u(0) \in B_{\sigma pq}$ is fixed. Therefore, according to Lemma 5.1 and Lemma 5.2 we have

$$\|I(u_1) - I(u_2)\|_{\mathcal{E}_T} \leq \mathcal{C}(T^{\frac{1}{2} - \frac{1}{p} + \frac{\alpha}{2}} + T^{\frac{\alpha}{2} + \frac{1}{2} - \frac{1}{p} - \frac{1}{2}}) (M + \|z\|_{C([0,T];B_{\sigma pq})}) \|u_1 - u_2\|_{\mathcal{E}_T} \quad (5.13)$$

for a suitable constant $\mathcal{C}$ independent of $T$.

When $T$ is such that

$$\mathcal{C}(T^{\frac{1}{2} - \frac{1}{p} + \frac{\alpha}{2}} + T^{\frac{\alpha}{2} + \frac{1}{2} - \frac{1}{p} - \frac{1}{2}}) (M + \|z\|_{C([0,T];B_{\sigma pq})}) < 1 \quad (5.14)$$

the mapping $I$ is a contraction and hence has a unique fixed point, which is the unique solution of equation (5.1).

Notice that $T$ is a random time, since inequality (5.14) involves the random process $z$. It can be chosen to be a stopping time.

Since $v = z + u$, we also get existence of a local mild solution $v$ to equation (2.2) where the bilinear term $B(v,v)$ has to be understood as the sum of four terms, that is

$$dv(t) - Av(t) dt = -B(u(t), u(t)) dt - B(u(t), z(t)) dt$$
$$- B(z(t), u(t)) dt - B(z(t), z(t)) dt + dw^H(t) \quad (5.15)$$

**Theorem 5.7.** Let $\frac{7}{10} < H < \frac{1}{2}$ and the parameters fulfil the conditions (5.4)-(5.12). Then, given $v_0 \in B_{\sigma pq}$ there exist a stopping time $\tau \in [0,T]$ and for $\mathbb{P}$-a.e. $\omega$ a unique mild solution $v(\omega, \cdot)$ of equation (5.15) with values in $C([0, \tau(\omega)]; B_{\sigma pq})$. 

19
Remark 5.8. We cannot get a global existence result for \( v \) as in [1, 8]; indeed, when \( H = \frac{1}{2} \) the Gaussian measure \( \mu^H \) defined by (3.5) is invariant for the Navier-Stokes equation (2.2). This allows to define \( B(v, v) \) and to get global existence. However, when \( H \neq \frac{1}{2} \) the measure \( \mu^H \) is invariant for the Stokes equation (3.1) but not for the Navier-Stokes equation (2.2); this depends eventually on the fact that for \( 0 < H < 1 \) the Gaussian measure \( \mu^H \) is (formally) invariant for the deterministic Euler dynamics

\[
\frac{dv}{dt} = -B(v, v)
\]

only when \( H = \frac{1}{2} \) (and in this case \( \mu^{\frac{1}{2}} \) is called the enstrophy measure, see [2]).

5.2 \( \frac{1}{2} < H < 1 \)

When \( \frac{1}{2} < H < 1 \) the fBm \( w^H \) and the Stokes process \( z \) are more regular and we expect more regularity of the processes \( u \) and \( v \) too. Actually we can obtain an a priori energy estimate; this will lead to global existence. Let us notice that now we deal with solutions which are weak in the sense of PDE’s; for instance the solution \( u \) of equation (5.1) has paths at least in \( L^\infty(0, T; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^1) \) and fulfills for any \( t > 0 \) and any \( \varphi \in \mathcal{H}^1 \)

\[
\langle u(t) - u(0), \varphi \rangle - \int_0^t \langle Au(s), \varphi \rangle ds + \int_0^t \langle B(u(s), \varphi), u(s) \rangle ds \\
+ \int_0^t \langle B(u(s), \varphi), z(s) \rangle ds + \int_0^t \langle B(z(s), \varphi), u(s) \rangle ds = - \int_0^t \langle B(z(s), z(s)), \varphi \rangle ds
\]

\( \mathbb{P}\text{-a.s..} \) This is obtained from (5.1) by using (2.5).

Since the paths of the process \( u \) are in \( L^\infty(0, T; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^1) \) and those of \( z \) are in \( C([0, T]; \mathcal{H}^\sigma) \) for some \( \sigma > 0 \), then all the terms in the latter relationship are well defined. Let us check the trilinear terms, by using Hölder inequality, interpolation inequality and Sobolev embeddings:

\[
|\langle B(u(s), \varphi), u(s) \rangle| \leq \|u(s)\|_{L^4}^2 \|\varphi\|_{\mathcal{H}^1} \leq C\|u(s)\|_{\mathcal{H}^0} \|u(s)\|_{\mathcal{H}^1} \|\varphi\|_{\mathcal{H}^1}
\]

\[
|\langle B(u(s), \varphi), z(s) \rangle| \leq \|u(s)\|_{L^{\frac{5}{3}}} \|\varphi\|_{\mathcal{H}^1} \|z(s)\|_{L^{\frac{5}{3}}} \quad \text{for } 0 < \sigma < 1
\]

\[
\leq C\|u(s)\|_{\mathcal{H}^1} \|\varphi\|_{\mathcal{H}^1} \|z(s)\|_{\mathcal{H}^\sigma}
\]

The third trilinear term can be dealt with as with the second term. And finally the latter term is well defined as soon as \( B(z(s), z(s)) \in L^1(0, T; \mathcal{H}^{-1}) \) (see Remark 4.3).
Hence, we get the usual energy estimate (see [20]). We make use of (2.6) and (2.7):

\[
\frac{1}{2} \frac{d}{dt} \|u(t)\|_{H^0}^2 + \|\nabla u(t)\|_{L^2}^2 = -\langle B(u(t) + z(t), u(t)), u(t)\rangle - \langle B(u(t), z(t)), u(t)\rangle - \langle B(z(t), z(t)), u(t)\rangle
\]

\[
\leq \|B(u(t), z(t))\|_{\mathcal{H}^{-1}} \|u(t)\|_{\mathcal{H}^1} + \|B(z(t), z(t))\|_{\mathcal{H}^{-1}} \|u(t)\|_{\mathcal{H}^1}
\]

\[
\leq C \|u(t)\|_{\mathcal{H}^{1-\sigma}} \|z(t)\|_{\mathcal{H}^\sigma} \|u(t)\|_{\mathcal{H}^1} + \frac{1}{4} \|u(t)\|_{\mathcal{H}^1}^2 + C \|B(z(t), z(t))\|_{\mathcal{H}^{-1}}^2
\]

Moreover, by interpolation and Young inequality

\[
\|u\|_{\mathcal{H}^{1-\sigma}} \|z\|_{\mathcal{H}^\sigma} \|u\|_{\mathcal{H}^1} \leq C \|u\|_{\mathcal{H}^0}^\sigma \|u\|_{\mathcal{H}^1}^{1-\sigma} \|z\|_{\mathcal{H}^\sigma} \|u\|_{\mathcal{H}^1}
\]

\[
= C \|u\|_{\mathcal{H}^0}^\sigma \|u\|_{\mathcal{H}^1}^{2-\sigma} \|z\|_{\mathcal{H}^\sigma}
\]

\[
\leq \frac{1}{4} \|u\|_{\mathcal{H}^1}^2 + C \|u\|_{\mathcal{H}^0}^2 \|z\|_{\mathcal{H}^\sigma}^2
\]

Since \( \|u\|_{\mathcal{H}^1}^2 = \|u\|_{\mathcal{H}^0}^2 + \|\nabla u\|_{L^2}^2 \), collecting all the estimates we have found

\[
\frac{d}{dt} \|u(t)\|_{\mathcal{H}^0}^2 + \|\nabla u(t)\|_{L^2}^2 \leq C (1 + \|z\|_{\mathcal{H}^\sigma}^2) \|u\|_{\mathcal{H}^0}^2 + C \|B(z(t), z(t))\|_{\mathcal{H}^{-1}}^2
\]

According to Remark 4.3, \( B(z, z) \in L^2(0, T; \mathcal{H}^{-1}) \). Moreover \( z \in C([0, T]; \mathcal{H}^\sigma) \) by Proposition 3.2. This provides as usual by means of Gronwall Lemma that \( u \in L^\infty(0, T; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^1), \mathbb{P}\)-a.s. The reader can see all the details of this standard procedure in [20]. First one has to work on the finite dimensional approximation and then pass to the limit. By interpolation

\[
u = z + u \in L^\infty(0, T; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^\sigma).
\]

Hence, \( v = z + u \in L^\infty(0, T; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^\sigma) \).

We can improve the estimates, now getting \( u \in C([0, T]; \mathcal{H}^\sigma) \cap L^2(0, T; \mathcal{H}^{1+\sigma}) \).

This gives global existence for the process \( v = z + u \) in the space \( C([0, T]; \mathcal{H}^\sigma) \) for \( 0 < \sigma < 2(H - \frac{1}{2}) \). Therefore the term \( B(v, v) \) is well defined. Actually the process \( v \) is a weak solution (in the sense of PDE’s) to equation (5.16), that is it solves for any \( t > 0 \) and any \( \varphi \in \mathcal{H}^{2-\sigma} \)

\[
\langle v(t) - v_0, \varphi \rangle = \int_0^t \langle Av(s), \varphi \rangle ds + \int_0^t \langle B(v(s), \varphi), v(s) \rangle ds = \langle w^H(t), \varphi \rangle
\]
We leave to the reader to check that all terms are well defined (use that $2 - \sigma > 1$). Similarly, the process $z$ can be considered as a weak solution of the stochastic Stokes equation (3.1).

**Theorem 5.9 (Global existence).** Let $\frac{1}{2} < H < 1$ and

$$0 < \sigma < 2(H - \frac{1}{2}).$$

(5.17)

Given $v_0 \in \mathcal{H}^{\sigma}$ there exists a $C([0, T]; \mathcal{H}^{\sigma}) \cap L^2(0, T; \mathcal{H}^{1+\sigma})$-valued process $u$ solving equation (5.1) with $u(0) = v_0 - z(0)$. Therefore there exists a $C([0, T]; \mathcal{H}^{\sigma})$-valued process $v$ solving equation (2.2) with $v(0) = v_0$.

**Proof.** We have to work on

$$\frac{1}{2} \frac{d}{dt} \|u(t)\|^2_{\mathcal{H}^{\sigma}} + \|\nabla u(t)\|^2_{\mathcal{H}^{\sigma}}$$

$$= -\langle B(u(t) + z(t), u(t)), (-A)^{\sigma} u(t) \rangle - \langle B(u(t), z(t)), (-A)^{\sigma} u(t) \rangle$$

$$- \langle B(z(t), z(t)), (-A)^{\sigma} u(t) \rangle$$

We perform the estimates on the terms in the r.h.s. Notice that $0 < \sigma < 1$.

From (2.7), the interpolation inequality $\|u\|_{\mathcal{H}^1} \leq C\|u\|_{\mathcal{H}^{\sigma}}\|u\|_{1+\sigma}$ and Young inequality we get

$$\langle B(u, (-A)^{\sigma} u) \rangle \leq \|B(u, u)\|_{\mathcal{H}^{\sigma-1}}\|u\|_{\mathcal{H}^{\sigma+1}}$$

$$\leq C\|u\|_{\mathcal{H}^{\sigma}}\|u\|_{\mathcal{H}^1}\|u\|_{1+\sigma}$$

$$\leq C\|u\|_{1+\sigma}\|u\|_{2-\sigma}$$

$$\leq \frac{1}{8}\|u\|_{2+\sigma} + C\|u\|_{\mathcal{H}^{\sigma}}\|u\|_{\mathcal{H}^\sigma}$$

$$\langle B(z, (-A)^{\sigma} u) \rangle \leq \|B(z, u)\|_{\mathcal{H}^{\sigma-1}}\|u\|_{\mathcal{H}^{\sigma+1}}$$

$$\leq C\|z\|_{\mathcal{H}^{\sigma}}\|u\|_{\mathcal{H}^1}\|u\|_{1+\sigma}$$

$$\leq C\|z\|_{\mathcal{H}^{\sigma}}\|u\|_{\mathcal{H}^{\sigma}}\|u\|_{2-\sigma}$$

$$\leq \frac{1}{8}\|u\|_{2+\sigma} + C\|z\|_{\mathcal{H}^{\sigma}}\|u\|_{\mathcal{H}^\sigma}$$

$$\langle B(u, z), (-A)^{\sigma} u \rangle \leq \|B(u, z)\|_{\mathcal{H}^{\sigma-1}}\|u\|_{\mathcal{H}^{\sigma+1}}$$

$$\leq C\|u\|_{\mathcal{H}^1}\|z\|_{\mathcal{H}^{\sigma\epsilon}}\|u\|_{1+\sigma}$$

$$\leq C\|u\|_{\mathcal{H}^{\sigma}}\|z\|_{\mathcal{H}^{\sigma\epsilon}}\|u\|_{1+\sigma}$$

$$\leq \frac{1}{8}\|u\|_{2+\sigma} + C\|z\|_{\mathcal{H}^{\sigma\epsilon}}\|u\|_{\mathcal{H}^\sigma}$$
where \(0 < \epsilon \ll 1\), and
\[
\langle B(z, z), (-A)^\sigma u \rangle \leq \|B(z, z)\|_{\mathcal{H}^{\sigma-1}} \|u\|_{\mathcal{H}^{\sigma+1}}
\]
\[
\leq \frac{1}{8} \|u\|_{\mathcal{H}^{1+\sigma}}^2 + C \|B(z, z)\|_{\mathcal{H}^{\sigma-1}}^2
\]

Now, \(\|u\|_{\mathcal{H}^{1+\sigma}}^2 = \|u\|_{\mathcal{H}^{\sigma}}^2 + \|\nabla u\|_{\mathcal{H}^{\sigma}}^2\). Summing up
\[
\frac{d}{dt}\|u(t)\|_{\mathcal{H}^\sigma}^2 + \|\nabla u(t)\|_{\mathcal{H}^\sigma}^2 \leq C(1 + \|u\|_{\mathcal{H}^\sigma}^2 + \|\nabla u\|_{\mathcal{H}^{\sigma+\epsilon}}^2 + \|B(z, z)\|_{\mathcal{H}^{\sigma-1}}^2)\|u\|_{\mathcal{H}^\sigma}^2.
\]

Now we bear in mind (5.16), Proposition 3.2 with \(\epsilon \ll 1\) and Proposition 4.1 to deal with the sum in the r.h.s.. So by means of Gronwall lemma we conclude that \(u \in L^\infty(0, T; \mathcal{H}^\sigma) \cap L^2(0, T; \mathcal{H}^{\sigma+1})\). In addition, by means of the previous estimates we get
\[
\frac{d}{dt} u = Au - B(u, u) - B(u, z) - B(z, u) - B(z, z) \in L^2(0, T; \mathcal{H}^{\sigma-1}).
\]
Since \(u \in L^2(0, T; \mathcal{H}^{\sigma+1})\), one gets that \(u \in C([0, T]; \mathcal{H}^\sigma)\) (see [20]). Hence \(v = u + z \in C([0, T]; \mathcal{H}^\sigma)\).

The solution obtained is also unique. We have a pathwise uniqueness result.

**Theorem 5.10** (Uniqueness). Let \(\frac{1}{2} < H < 1\) and \(0 < \sigma < 2(H - \frac{1}{2})\). Given \(v_0 \in \mathcal{H}^\sigma\) there exists a unique \(C([0, T]; \mathcal{H}^\sigma)\)-valued process solving (2.2).

**Proof.** Let \(v_1, v_2 \in C([0, T]; \mathcal{H}^\sigma)\) be solutions of (2.2). Then the difference \(V = v_1 - v_2\) fulfils
\[
\frac{dV}{dt} + AV = -B(v_1, v_1) + B(v_2, v_2)
\]
with \(V(0) = 0\). We are going to prove that \(V(t) = 0\) for all \(t \geq 0\) and this is obtained by means of the a priori estimate of the energy. Actually the paths of \(V\) are more regular than those of \(v_1\) and \(v_2\), since the noise term has disappeared in (5.18); this was remarked already in [13]. More precisely, we state that any solution \(V\) of (5.18) with \(V(0) = 0\) is such that \(V \in C([0, T]; \mathcal{H}^0) \cap L^2(0, T; \mathcal{H}^1)\) and \(\frac{dV}{dt} \in L^2(0, T; \mathcal{H}^{-1})\); therefore the equality \(\frac{d}{dt}\|V(t)\|_{\mathcal{H}^0}^2 = 2\langle \frac{dV}{dt}(t), V(t) \rangle\) holds and the energy estimates (coming later) are justified.

Indeed we are given \(v_1, v_2 \in C([0, T]; \mathcal{H}^\sigma)\) with \(\sigma \in (0, 1)\). The r.h.s. of (5.18) belongs to \(L^\infty(0, T; \mathcal{H}^{2\sigma-2})\), since
\[
\|B(v_1, v_1)\|_{\mathcal{H}^{2\sigma-2}} \leq C\|v_1\|_{\mathcal{H}^\sigma}\]

23
by \((2.7)\). According to Proposition \(3.5\) (used with vanishing initial data and \(r = 2\)) we get that any solution \(V\) will be in \(L^2(0, T; \mathcal{H}^{2\sigma})\).

If \(2\sigma \geq 1\) (i.e. when \(\frac{1}{\sigma} \leq \sigma < 1\)) we have obtained that \(V \in L^2(0, T; \mathcal{H}^1)\); moreover, \(\frac{dV}{dt} = -AV + B(v_1, v_1) - B(v_2, v_2)\) and therefore \(\frac{dV}{dt} \in L^2(0, T; \mathcal{H}^{-1})\).

Otherwise, when \(0 < \sigma < \frac{1}{2}\) we proceed as follows; by the bilinearity of \(B\) we get that \((5.18)\) can be written as

\[
\frac{dV}{dt} + AV = -B(v_1, V) - B(V, v_2)
\]  

Let us look at the regularity of the r.h.s., knowing that \(v_1, v_2 \in C([0, T]; \mathcal{H}^\sigma)\) and \(V \in C([0, T]; \mathcal{H}^\sigma) \cap L^2(0, T; \mathcal{H}^{2\sigma})\).

Thanks to \((2.7)\) we get, for \(0 < \sigma < \frac{1}{2}\)

\[
\|B(v_1, V)\|_{\mathcal{H}^{4\sigma-2}} \leq C\|v_1\|_{\mathcal{H}^\sigma}\|V\|_{\mathcal{H}^{2\sigma}}
\]

\[
\|B(V, v_2)\|_{\mathcal{H}^{4\sigma-2}} \leq C\|V\|_{\mathcal{H}^{2\sigma}}\|v_2\|_{\mathcal{H}^\sigma}
\]

Hence the r.h.s. of \((5.19)\) belongs to \(L^2(0, T; \mathcal{H}^{4\sigma-2})\) and therefore thanks to Proposition \(3.3\) any solution \(V\) belongs to \(L^2(0, T; \mathcal{H}^{2\sigma})\).

If \(3\sigma \geq 1\) (i.e. when \(\frac{1}{\sigma} \leq \sigma < \frac{1}{2}\) we have obtained that \(V \in L^2(0, T; \mathcal{H}^1)\) and moreover the r.h.s. of \((5.19)\) belongs to \(L^2(0, T; \mathcal{H}^{3\sigma-2}) \subseteq L^2(0, T; \mathcal{H}^{-1})\).

Hence we conclude as in the previous case about \(\frac{dV}{dt}\).

Otherwise, for smaller values of \(\sigma\) we proceed again with the bootstrap argument. We conclude that, given \(\sigma \in (0, 1)\) and \(v_1 \in C([0, T]; \mathcal{H}^\sigma)\), any solution \(V\) to \((5.19)\) is in \(L^2(0, T; \mathcal{H}^1)\) and \(\frac{dV}{dt} \in L^2(0, T; \mathcal{H}^{-1})\).

Now, we look for the a priori energy estimate. Keeping in mind \((2.6)\), \((2.7)\) and the interpolation inequality \(\|V\|_{\mathcal{H}^{1-\sigma}} \leq C\|V(t)\|_{\mathcal{H}^0}^{\sigma}\|V(t)\|_{\mathcal{H}^1}^{1-\sigma}\), we get

\[
\frac{1}{2}\frac{d}{dt}\|V(t)\|_{\mathcal{H}^0}^2 + \|
abla V(t)\|_{L^2}^2 = -(B(v_1(t), V(t)), V(t)) - (B(V(t), v_2(t)), V(t))
\]

\[
= (B(V(t), V(t)), v_2(t))
\]

\[
\leq \|B(V(t), V(t))\|_{\mathcal{H}^{-1}}\|v_2(t)\|_{\mathcal{H}^\sigma}
\]

\[
\leq C\|V(t)\|_{\mathcal{H}^{1-\sigma}}\|V(t)\|_{\mathcal{H}^1}\|v_2(t)\|_{\mathcal{H}^\sigma}
\]

\[
\leq C\|V(t)\|_{\mathcal{H}^0}^{\sigma}\|V(t)\|_{\mathcal{H}^1}^{2-\sigma}\|v_2(t)\|_{\mathcal{H}^\sigma}
\]

\[
\leq \frac{1}{2}\|V(t)\|_{\mathcal{H}^1}^2 + C\|v_2(t)\|_{\mathcal{H}^\sigma}^2\|V(t)\|_{\mathcal{H}^0}^2
\]

\[
= \frac{1}{2}\|V(t)\|_{\mathcal{H}^0}^2 + \frac{1}{2}\|
abla V(t)\|_{L^2}^2 + C\|v_2(t)\|_{\mathcal{H}^\sigma}^2\|V(t)\|_{\mathcal{H}^0}^2
\]

From

\[
\frac{d}{dt}\|V(t)\|_{\mathcal{H}^0}^2 \leq C(1 + \|v_2(t)\|_{\mathcal{H}^\sigma}^2)\|V(t)\|_{\mathcal{H}^0}^2
\]
we conclude by Gronwall lemma that $\sup_{0 \leq t \leq T} \|V(t)\|_{\mathcal{H}_0} = 0$. This proves pathwise uniqueness. \hfill \Box

A Auxiliary results

We prove some results about convergence of series.

Lemma A.1. For any $k \in \mathbb{Z}^2_0$, the series

$$\sum_{h \in \mathbb{Z}^2_0, h \neq k} \frac{1}{|h|^{1H}|k-h|^{1H}}$$

converges if $H > \frac{1}{4}$ and its sum $S_1(k)$ depends on $k$ as follows

$$S_1(k) \leq \begin{cases} 
M_H \frac{1}{|k|^{1H}} & \text{if } \frac{1}{4} < H < \frac{1}{2} \\
M_H \ln |k| & \text{if } H = \frac{1}{2} \\
M_H \frac{1}{|k|^{1H}} & \text{if } H > \frac{1}{2}
\end{cases}$$

for some positive constants $M$ and $M_H$ independent of $k$.

Proof. The series can be estimated by the following integral

$$\iint_{D_k} \frac{dx \, dy}{(x^2 + y^2)^{2H} ((x-k^1)^2 + (y-k^2))^{2H}}$$

over the region $D_k$ which is the plane without two unitary balls around the points $k$ and 0. Therefore it is enough to evaluate

$$I_1(a) = \iint_{D_a} \frac{dx \, dy}{(x^2 + y^2)^{2H} ((x-a)^2 + y^2)^{2H}}$$

for $a \geq 2$, where $D_a = \mathbb{R}^2 \setminus (B_1((0,0)) \cup B_1((a,0)))$ and $B_r((c,d))$ denotes the ball of radius $r$ with center $(c,d)$.

Now we make a change of variables: $u = \frac{x}{a}$ and $v = \frac{y}{a}$. The domain $D_a$ becomes the domain $R_a = \mathbb{R}^2 \setminus (B_1((0,0)) \cup B_1((1,0)))$. Hence

$$I_1(a) = \frac{1}{a^{8H}} \iint_{R_a} \frac{a^2}{(u^2 + v^2)^{2H} ((u-1)^2 + v^2)^{2H}} \, du \, dv.$$ 

We split the integral region into three disjoint regions: $R_a^0 = B_{\frac{1}{2}}((0,0)) \setminus B_{\frac{1}{2}}((0,0))$, $R_a^1 = B_{\frac{1}{2}}((1,0)) \setminus B_{\frac{1}{2}}((1,0))$ and $R^\infty = R_a \setminus (R_a^0 \cup R_a^1)$. 

\hfill 25
By symmetry the integral over \( R_0 \) is the same as that over \( R_1 \) and we have
\[
\int\int_{R_0} \frac{du \, dv}{(u^2 + v^2)^{2H}} \leq \int\int_{R_0} \frac{du \, dv}{((u-1)^2 + v^2)^{2H}}
\]
\[
= 2^{4H} 2\pi \int_{1/a}^{1/2} r \, dr
\]
\[
\leq \begin{cases} 
\frac{2^{8H-3} \pi}{\frac{1}{4} - H} & \text{if } \frac{1}{4} < H < \frac{1}{2} \\
8\pi \ln a & \text{if } H = \frac{1}{2} \\
\frac{2^{4H-1} \pi}{H - \frac{1}{2}} a^{4H-2} & \text{if } H > \frac{1}{2}
\end{cases}
\]
The integral over \( R_\infty \) is a constant \( \hat{C}_H \) independent of \( a \), when \( H > \frac{1}{4} \).

Summing up, we get that there exist positive constants \( M \) and \( M_H \) such that
\[
I_1(a) \leq \begin{cases} 
M_H a^{\frac{1}{4H-2}} & \text{if } \frac{1}{4} < H < \frac{1}{2} \\
M_H a^{rac{1}{2}} & \text{if } H = \frac{1}{2} \\
M_H a^{4H} & \text{if } H > \frac{1}{2}
\end{cases}
\]
Returning to the notation with \( k \) we get our result. \( \square \)

In the next Lemma we consider a restricted range for \( H \); the assumption on \( \rho \) is a restriction of that in (4.2).

**Lemma A.2.** We are given \( \frac{1}{2} < H < 1 \). Let us assume \(-1 < \rho < 2(H - 1)\). Then, for any \( k \in \mathbb{Z}^2_0 \) the series
\[
\sum_{h \in \mathbb{Z}^2_0, h \neq k} \frac{|h|^{2\rho+2}}{|h|^{4H}|k - h|^{4H}}
\]
converges and its sum \( S_2(k) \) is bounded by
\[
C_H \frac{1}{|k|^{4H-2\rho-2}}
\]
for a suitable constant \( C_H \).

**Proof.** By assumption we have \( 4H + 4H - 2\rho - 2 > 2 \) and therefore the series is convergent. To estimate its sum we proceed as in the proof of the previous Lemma. First the series can be estimated by an integral and it is enough to evaluate
\[
I_2(a) = \int\int_{D_a} \frac{dx \, dy}{(x^2 + y^2)^{2H-\rho-1} ((x-a)^2 + y^2)^{2H}}
\]
for $a \geq 2$. By the change of variables $u = \frac{x}{a}$ and $v = \frac{y}{a}$ we obtain

$$I^2(a) = \frac{1}{a^{2(4H-\rho-1)}} \iint_{R_a} \frac{a^2}{(u^2 + v^2)^{2H-\rho-1} ((u-1)^2 + v^2)^{2H}} \, du \, dv.$$ 

We split the integral over $R_a$ into three parts by setting $R_a = R^0_a \cup R^1_a \cup R^\infty$ with disjoint unions:

- **over** $R^0_a = B_\frac{1}{a}((0,0)) \setminus B_1((0,0))$

$$ \iint_{R^0_a} \frac{du \, dv}{(u^2 + v^2)^{2H-\rho-1} ((u-1)^2 + v^2)^{2H}} \leq 2^{4H} \int_{R^0_1} \frac{du \, dv}{(u^2 + v^2)^{2H-\rho-1}} = 2^{4H} \frac{2\pi}{2(2H-\rho-1)} \int_{1/a}^{1/2} r \, dr.$$ 

By assumption we get that $2(2H - \rho - 1) - 1 > 1$; therefore the latter integral is bounded by $C_H a^{4H-2\rho-4}$

- **over** $R^1_a = B_\frac{1}{a}((1,0)) \setminus B_1((1,0))$ we proceed as in the proof of the previous Lemma and get that the integral over $R^1_a$ is bounded by

$$C_H a^{4H-2}$$

- **over** $R^\infty = R_a \setminus (R^0_a \cup R^1_a)$: this integral is bounded, uniformly in $a$.

Now we compare the exponents of $a$; since $\rho > -1$, we have $4H - 2\rho - 4 < 4H - 2$. Summing the three contributions and noticing that $4H - 2 > 0$ we conclude that the integral over the region $R_a$ is bounded by $C_H a^{4H-2}$ for all $a \geq 2$. Thus

$$I^2(a) \leq C_H \frac{1}{a^{4H-2\rho-2}} \quad \forall a \geq 2$$

for a suitable constant $C_H$. \hfill \Box

**Lemma A.3.** Let $\frac{1}{4} < H < 1$ and

- $\rho < 4H - 3$ if $\frac{1}{4} < H < \frac{1}{2}$ \hspace{1cm} (1.1)

- $\rho < 2(H - 1)$ if $\frac{1}{2} < H < 1$ \hspace{1cm} (1.2)

Then

$$\sum_{j \in \mathbb{Z}_0^d} |j|^{2\rho+2} \sum_{h \neq j \neq l} |h|^{4H} |l|^{4H} |h-j|^{4H} |l-j|^{4H} < \infty.$$
Proof. First let us prove it when $2\rho + 2 > 0$; this is possible only when $\frac{1}{2} < H < 1$. In this case we have

$$|h - l| \leq 2|h||l|$$

which holds for any $h, l \in \mathbb{Z}_0^2$. It comes from

$$1 + \frac{|l|}{|h|} \leq 1 + |l| \leq 2|l| \quad \forall|h|, |l| \geq 1;$$

this is equivalent to

$$|h| + |l| \leq 2|h||l|$$

Thus, by triangle inequality we obtain (A.1).

Hence with a positive power we get

$$|h - l|^{2\rho + 2} \leq C|h|^{2\rho + 2}|l|^{2\rho + 2}$$

This implies that we study the series

$$\sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \sum_{h \neq j, l \neq j} \frac{|h|^{2\rho + 2}|l|^{2\rho + 2}}{|h|^{4H}|l|^{4H}|h - j|^{4H}|l - j|^{4H}} = \sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \left( \sum_{h \neq j} \frac{|h|^{2\rho + 2}}{|h|^{4H}|h - j|^{4H}} \right)^2.$$

The inner series is estimated by Lemma A.2, thus

$$\sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \left( \sum_{h \neq j} \frac{|h|^{2\rho + 2}}{|h|^{4H}|h - j|^{4H}} \right)^2 \leq C_H \sum_{j \in \mathbb{Z}_0^2} \frac{1}{|j|^{2(4H - 3\rho - 3)}}$$

The assumption (4.2) implies that $2(4H - 3\rho - 3) > 2$ and therefore this latter series is convergent.

Now let us consider the case $2\rho + 2 \leq 0$. We have $|h - l|^{(2\rho + 2)} \leq 1$. Therefore we are left with

$$\sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \sum_{h \neq j, l \neq j} \frac{1}{|h|^{4H}|l|^{4H}|h - j|^{4H}|l - j|^{4H}} = \sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \left( \sum_{h \neq j} \frac{1}{|h|^{4H}|h - j|^{4H}} \right)^2$$

We handle this contribution according to Lemma A.1. Indeed it is bounded by

$$\sum_{j \in \mathbb{Z}_0^2} |j|^{2\rho + 2} \times \begin{cases} M_H \frac{1}{|j|^{2(\frac{3}{2}H - 1)}} & \text{if } \frac{1}{4} < H < \frac{1}{2} \\ M_H \frac{\ln |j|}{|j|^{1/4}} & \text{if } H = \frac{1}{2} \\ M_H |j|^{8\pi} & \text{if } H > \frac{1}{2} \end{cases}$$
Thus there is convergence if
\[
\begin{cases}
16H - 4 - 2\rho - 2 > 2 \quad \text{if } \frac{1}{2} < H < \frac{1}{2}
\end{cases}
\]
\[
\begin{cases}
4 - 2\rho - 2 > 2 \quad \text{if } H = \frac{1}{2}
\end{cases}
\]
\[
\begin{cases}
8H - 2\rho - 2 > 2 \quad \text{if } H > \frac{1}{2}
\end{cases}
\]

These conditions are fulfilled under assumptions (4.1) and (4.2).

B  The case $m = 2$

We present the proof of Proposition 4.1 for the case $m = 2$.

First we shall use many times that $\gamma_{h,k} = \gamma_{k-h,k}$ and $\gamma_{h,k}^2 \leq |k|^2$ for any $h$. We have
\[
\int \left\| B(z, z) \right\|_{4^{\rho \mu}}^{4} \mu^H (dz)
\]
\[
= \int \left( \sum_{k \in Z_0^2} |k|^{2\rho |B_k(z, z)|^2} \right)^2 \mu^H (dz)
\]
\[
= \sum_{k \in Z_0^2} \sum_{j \in Z_0^2} |k|^{2\rho |j|^{2\rho}} \int |B_k(z, z)|^2 |B_j(z, z)|^2 \mu^H (dz)
\]
\[
= \sum_{k \in Z_0^2} \sum_{j \in Z_0^2} |k|^{2\rho |j|^{2\rho}} \sum_{h, h' \in Z_0^2, h, h' \neq k, l, l' \in Z_0^2, l, l' \neq j} \int \gamma_{h,k} \gamma_{h,k} z_h z_{k-h} \gamma_{k-h} \gamma_{k-h} \gamma_{l,j} \gamma_{l,j} \gamma_{l,j} \gamma_{l,j} \mu^H (dz)
\]

Now we consider the series. There are indeed 6 sums but we have to consider only the non vanishing integrals: $\mu^H$ is the product of centered Gaussian measures and all odd powers give zero contribution in the integral with respect to the measure $\mu^H$. In particular we analyze
\[
\int z_h z_{k-h} z_{h' / h} z_{k-h'} z_{l-j} z_{l'-j'} \mu^H (dz)
\]

We get different contributions according to the choice of equal indices. Let us list all these possible contributions; we choose $h$ equal to some subsequent index but the case leading to $z_h = \overline{z_{k-h}}$ is not possible since $k \neq 0$. Therefore there are 6 possible cases. In the following we do not specify that the sum involves indices belonging to $Z_0^2$ in order to shorten the notation.
1. When \( h = h' \):
   
   - for \( l = l' \) we get
     \[
     \sum_k \sum_j |k|^{2\rho} |j|^{2\rho} \sum_{h \neq k, l \neq j} \int |\gamma_{h,k}^{2} z_h|^{2} |z_{k-h}|^{2} |\gamma_{l,j}^{2} z_l|^{2} |z_{j-l}|^{2} \mu^{H}(dz) = \left( \sum_k |k|^{2\rho} \sum_{h \neq k} \int |\gamma_{h,k}^{2} z_h|^{2} |z_{k-h}|^{2} \mu^{H}(dz) \right)^2
     \]
   
   We know from (4.4) that the quantity in the parenthesis is finite under assumptions (4.1) and (4.2).
   
   - for \( l = j - l' \) we get as before.

2. When \( h = k - h' \):
   
   - for \( k - l = l' \) we get as before;
   
   - for \( l = j - l' \) we get as before.

3. When \( h = -l \) we get
   
   \[
   \sum_k \sum_j |k|^{2\rho} |j|^{2\rho} \sum_{h \neq k, -h \neq k, l' \neq j} \sum_{\gamma_{h,k} \gamma_{h',k} \gamma_{-h,j} \gamma_{h',j}} \int |z_{h}|^{2} |z_{k-h}^{2} z_{-h}^{2} z_{j+h}^{2} z_{j-l'} \mu^{H}(dz)
   \]
   
   This gives
   
   - for \( k = h \) or \( h = h' \)
     \[
     \sum_k \sum_j |k|^{2\rho} |j|^{2\rho} \sum_{h \neq k, -l \neq j} \int |\gamma_{h,k}^{2} z_h|^{2} |z_{k-h}|^{2} |z_{-h}^{2} z_{h}^{2} z_{l+h}^{2} z_{j-l'} \mu^{H}(dz) = \sum_k \sum_j |k|^{2\rho} |j|^{2\rho} \sum_{h \neq k, -l \neq j} \gamma_{h,k}^{2} \left( \gamma_{-h,j}^{2} + \gamma_{-h,j} \gamma_{h,j} \right) \int |z_{h}|^{4} |z_{k-h}|^{2} |z_{j+h}|^{2} \mu^{H}(dz)
     \]
     \[
     \leq C \sum_k \sum_j |k|^{2\rho+2} |j|^{2\rho+2} \mu^{H}(dz) \leq C \sum_k \sum_{h \neq k, -l \neq j} \frac{1}{|k|^{4H}|k-h|^{4H}}
     \]
     \[
     = C \sum_h \frac{1}{|h|^{8H}} \left( \sum_{k \neq h} |k|^{2\rho+2} \frac{1}{|k-h|^{4H}} \right)^2
     \]
   
   The inner series converges for \( \rho < 2(H - 1) \) (i.e. \( 2\rho + 2 - 4H < -2 \); from (4.1) and (4.2) we know that this condition is fulfilled.
Moreover its sum depends on \( h \) in such a way that it vanishes when \( |h| \to \infty \); hence it is bounded. Thus we are left with the convergence of the first series \( \sum_h |h|^{-8H} \), which holds for any \( H > \frac{1}{4} \). So this contribution is finite.

- for \( k = -j \)

\[
\sum_{k} |k|^{4\rho} \sum_{h \neq k} \sum_{h' \neq k} \sum_{h'' \neq -k} \int \gamma_{h,k} |z_h|^{2} |z_{k-h}|^{2} \gamma_{h',k,\overline{k-h'}} (z_{k-h}-k) \gamma_{h',-k} \gamma_{h'-k} (z_{k-h'}-k) \frac{1}{|z_{k-h}|^{2}|z_{k-h'}|^{2}} \mu^{H}(dz)
\]

\[
= C \sum_{k} |k|^{4\rho+4} \sum_{h \neq k} \sum_{h' \neq k} \frac{1}{|h|^{4H}|k-h|^{4H}|h'|^{4H}|k-h'|^{4H}}
\]

\[
= C \sum_{k} |k|^{4\rho+4} \left( \sum_{h \neq k} \frac{1}{|h|^{4H}|k-h|^{4H}} \right)^{2}
\]

We handle this contribution according to Lemma A.1. Indeed it is bounded by the series

\[
\sum_{k} |k|^{4\rho+4} \times \begin{cases} M_{H} \frac{1}{|k|^{8H}} & \text{if } \frac{1}{4} < H < \frac{1}{2} \\ M_{\ln |k|} \frac{1}{|k|^{4H}} & \text{if } H = \frac{1}{2} \\ M_{H} \frac{1}{|k|^{4H}} & \text{if } H > \frac{1}{2} \end{cases}
\]

Thus there is convergence if

\[
\begin{cases} 8H - 2 - 4\rho - 4 > 2 & \text{if } \frac{1}{4} < H < \frac{1}{2} \\ 2 - 4\rho - 4 > 2 & \text{if } H = \frac{1}{2} \\ 4H - 4\rho - 4 > 2 & \text{if } H > \frac{1}{2} \end{cases}
\]

These conditions are fulfilled under assumptions (4.1) and (4.2).

- for \( k - h = l' \)

\[
\sum_{j} |j|^{2\rho} \sum_{h \neq -j} \sum_{l' \neq -h,j} \sum_{h' \neq h+l'} |h + l'|^{2\rho} \gamma_{h,h+l'} (\gamma_{h',h+l'} \gamma_{h,j} \gamma_{l',j}) \int |z_h|^{2} |z_{l'}|^{2} |z_{h+l'-h} | z_{h+l'-j} \frac{1}{|z_{h+l'}|^{2}|z_{h+l'-h}||z_{h+l'-j}|}
\]

\[
= \sum_{j} |j|^{2\rho} \sum_{h \neq -j} \sum_{l' \neq -h,j} \int |h + l'|^{2\rho} \gamma_{h,h+l'} (\gamma_{h',h+l'} \gamma_{l'-j} \gamma_{l'-h}) \int |z_h|^{2} |z_{l'}|^{2} |z_{j+h}|^{2} |z_{j+l'}|^{2}
\]

\[
\leq C \sum_{j} |j|^{2\rho+2} \sum_{h \neq -j} \sum_{l' \neq -h,j} \frac{|h + l'|^{2\rho+2}}{|h|^{4H}|l'|^{4H}|j+h|^{4H}|h' - j|^{4H}}
\]
The convergence of this sums is done in Lemma A.3 in the Appendix.

- for \( k - h = j - l' \), we proceed as in the previous case.

4. when \( h = l - j \) we get

\[
\sum_{k} \sum_{j} |k|^{2p} |j|^{2p} \sum_{h \neq k, -j} \sum_{h' \neq k, l' \neq j} \gamma_{h,k} \gamma_{h',k} \gamma_{h+j,j} \gamma_{l',j} 
\int |z_h|^2 z_{k-h} z_{k-h'} z_{l'-j} z_{l'-j} \mu^H(dz)
\]

Estimating the \( \gamma \)'s (that is \( |\gamma_{.,k}| \leq C|k| \)) we get the same computations as in step 3.

5. when \( h = l' \) we get the same computations as in step 3.

6. when \( h = j - l' \) we get the same computations as in step 3.

This concludes the proof of (4.3) for \( m = 2 \).
