Theoretical investigation on nonlinear dynamic characteristic of spindle system

Xiangsheng Gao¹, Zeyun Qin¹, Min Wang¹,², Yuming Hao³ and Ziyu Liu⁴

Abstract
Radial gap will occur at the spindle–tool holder interface when the spindle rotates at high speed. Therefore, the radial gap will lead to the nonlinear stiffness at the spindle–tool holder connection, and it will have effects on dynamic characteristic of spindle system. In this research, classic elastic theory is adopted to evaluate the nonlinear stiffness at spindle–tool holder interface. Dynamic model of spindle system is established considering the nonlinear stiffness at spindle–tool holder interface. The fourth-order Runge–Kutta method is applied to solve dynamic response of the spindle system. On that basis, effects of drawbar force on dynamic characteristic of the system are investigated. Considering the cutting force, effects of rotational speed on dynamic response of cutter tip are also discussed. The numerical results show that the drawbar force has effects on vibration mode of cutter tip. Chaotic motion will not occur within the range concerned in engineering practice. Considering the cutting force, the motion of cutter tip turns to be chaotic. The proper rotational speed and drawbar force should be chosen to ensure a stable cutting according to the response of cutter tip.

Keywords
drawbar force, spindle, interface, nonlinear dynamic, cutter tip

Introduction
With the development of high-speed machining (HSM), higher demand for the spindle in machine tools are proposed. The interface of spindle–tool holder is the weak link in the whole spindle system. In the high-speed situation, the stiffness of interface at spindle–tool holder will decrease due to the centrifugal force. Relative displacement between spindle and tool holder may even occur. The variation of stiffness can be ignored in low rotational speed, but it must be considered in HSM.¹ Many researchers focus on this issue. The method can be mainly divided into finite element (FE) method and experimental method. Xu et al.² established a FE model of spindle–tool holder joint subjected to clamping and centrifugal forces, and numerical identification of contact stiffness was also conducted. Agapiou³ proposed a method for predicting the contact stiffness at spindle–tool holder interface based on two-dimensional FE analysis, and the method was validated by experimental results. Wang et al.⁴ established a dynamic model of high-speed spindle system with spindle-bearing joint and spindle–tool holder–tool joints. The influence of speed and cutting force was investigated. Yoon and Shen⁵ presented a numerical model predicting the shock response of a rotating-shaft spindle motor with nonlinear fluid dynamic bearings. Equations of motion were derived and numerically integrated to predict nonlinear shock response of the spindle. Gao et al.⁶ studied the nonlinear response of a machine-tool spindle system supported by ball bearings by the three-term harmonic balance method and numerical method. The influences of the bearing contact stiffness and the eccentricity on the
frequency response curves were studied, which presented some useful information to analyze and avoid the nonlinear response of spindle bearing system. Abeysuriya et al.\textsuperscript{7} modeled sleep spindles using a corticothalamic neural field model of the brain. Nonlinearity in the thalamic relay nuclei that produced a spindle harmonic oscillation was discussed. Jia et al.\textsuperscript{8} established a nonlinear dynamic model of the grinding motorized spindle system considering centrifugal force and bearing stiffness softening. Dynamic behavior was investigated, and the threshold of chaos motion of system was predicted. Cao et al.\textsuperscript{9} built an integrated FE model with the nonlinear of bearing which has outer ring defects. The Newmark time integration method was used to solve the vibration responses numerically. Nam et al.\textsuperscript{10} conducted the dynamical analysis and robust control synthesis for spindle machining system. A nonlinear model was established for the machine tool spindles. The phase portrait and bifurcation analyses were provided to show dynamical behaviors for spindle machining.

Hammering test is an effective method to identify contact stiffness at spindle–tool holder interfaces. Movahhedy and Gerami\textsuperscript{11} established a dynamic model of spindle–tool holder including linear stiffness and bending stiffness of the joint. The optimization method was employed to identify dynamic parameters based on hammering test results. Özşahin et al.\textsuperscript{12} identified the dynamic parameters of spindle bearing and tool–tool holder–spindle interface by impact testing at the stable situation. Apart from hammering test, Du and Hong\textsuperscript{13} proposed an ultrasonic method to measure the contact stiffness and contact stress distribution at spindle–tool holder interface.

Some other methods are developed to predict dynamic parameters of spindle–tool holder interface. Budak et al.\textsuperscript{14,15} established a dynamic model of spindle–holder–cutter system by receptance coupling substructure analysis method\textsuperscript{16–18} in their own research. Gao\textsuperscript{16} and Liao\textsuperscript{20} established a model for identifying the contact stiffness at spindle–tool holder interface based on fractal theory respectively. However, the contact stiffness at spindle–tool holder interface becomes nonlinear due to the high rotational speed and cutting force. Few research focused on it and discussed the influence on the dynamics of spindle system further. In this research, a nonlinear model for determining contact stiffness at spindle–tool holder is proposed based on the classic elasticity theory. On that basis, a nonlinear dynamic model of spindle system under cutting force, which takes into account the nonlinearity of spindle–tool holder stiffness and cutting force, is established. Effects of drawbar force and rotational speed on transient response of cutter tip are discussed.

**Nonlinearity of the contact stiffness of spindle–tool holder**

In high-speed rotation status, the radial gap will occur if the drawbar force is not great enough.\textsuperscript{1} The radial gap will lead to the nonlinear relationship between radial relative force $F_{x}$ at spindle–tool holder interface and radial relative displacement $d_{r}$.

The spindle and tool holder are both made of high-quality steel. Therefore, they have the same material property. According to the classic elasticity theory,\textsuperscript{21} for an annulus, with outside diameter $b$, inside diameter $a$, and thickness $h$ ($h \ll b$ and $a$), it can be modeled as a plane stress problem. When the annulus rotates around its center with the angular velocity $\omega$, the radial displacement of a certain node in the annulus which has the distance $r$ from the center is:

$$u_{r} = \frac{3 + \mu}{8E} \rho \omega^{2} r \left[ (1 - \mu) (b^{2} + a^{2}) + (1 + \mu) \frac{a^{2} b^{2}}{r^{2}} - \frac{1 - \mu^{2}}{3 + \mu} r^{2} \right]$$

where $E$, $\mu$, and $\rho$ are elastic modulus, Poisson’s ratio, and density of the material, respectively.

Cross-section sketch of a certain kind of spindle–tool holder is shown in Figure 1(a). The spindle and tool holder

![Figure 1. Spindle–tool holder: (a) sketch, (b) deformation.](image)
are axisymmetry. A three-dimensional Cartesian coordinate system $\theta xy z$ is established. The length of spindle–tool holder in $-y$ direction is much more than other sizes. Therefore, the spindle–tool holder can be simplified as a plane strain problem. According to the relationship between plane stress problem and plane strain problem, $E$ is substituted by $\frac{E}{1-\mu^2}$, and $\mu$ is substituted by $\frac{\mu}{1-\mu^2}$ in expression (1). When the hollow cylinder rotates around its axis with the angular velocity $\omega$, the radial displacement caused by centrifugal force $\rho \omega^2 r$ can be drawn.

$$u_r = \frac{(3 - 2\mu)(1 + \mu)}{8E(1 - \mu)} \rho \omega^2 r \left[ (1 - 2\mu)(r_1^2 + r_2^2) + \frac{r_1^2 r_2^2}{r^2} - \frac{1 - 2\mu}{3 - 2\mu} r^2 \right]$$

where $r_1$ and $r_2$ are inside diameter and outside diameter of the hollow cylinder, respectively.

For the spindle and tool holder that are described in Figure 1(a), the radius of the interface whose normal position of a feature node from tool holder and spindle is $s$, and $d$ are the radial displacement of node at the interface of spindle–tool holder can be expressed as:

$$u_s = \frac{(3 - 2\mu)(1 + \mu)}{4E} \rho \omega^2 r \left[ b^2 + \frac{1 - 2\mu}{3 - 2\mu} r^2 \right],$$

$$u_t = \frac{(1 - 2\mu)(1 + \mu)}{4E} \rho \omega^2 r^3,$$

where $u_s$ and $u_t$ are the radial displacements of nodes at the interface of spindle–tool holder at $y$ is:

$$\delta = u_s - u_t = \frac{(3 - 2\mu)(1 + \mu)}{4E} \rho \omega^2 rb^2$$

The relationship among $u_s$, $u_t$, and $\delta$ is depicted in Figure 1(b). $W$ is a plane parallel to the end surface of tool holder. The blue solid line is the interface before deformation. The intersection between blue line and $W$ is the original position of a feature node from tool holder and spindle at the interface, which are marked as $P_s$ and $P_t$. With the rotation introduced, the deformation occurs. The green dotted line represents the position of tool holder, while the red one represents the position of spindle after deformation. $P_t$ and $P_s$ are the positions of feature nodes. Therefore, $u_s = P_t P_s$, $u_t = P_t P_s$; and $\delta = P_s P_t$.

The connection between spindle and tool holder is an interference fit. Contact stress at the interface under the action of drawbar force and cutting force is:

$$\sigma = \begin{cases} 
E(b_0 - \delta - \delta' \cos \theta)(b^2 - 4r^2) & \delta - \delta' \cos \theta > 0 \\
0 & \delta - \delta' \cos \theta \leq 0 
\end{cases}$$

The equilibrium equation of tool holder in $-y$ direction shown in Figure 1 can be drawn as follows:

$$\int S \sigma \sin \varphi dS = 4\int_0^\varphi \int_0^r \sigma \sin \varphi r \vartheta d\vartheta dy = F_y$$

where $F_y$ is the drawbar force; $\varphi$ is the angle between the interface and $y$-axis. $S$ represents the spindle–tool holder interface. When expression (5) is introduced into expression (6), $\delta_0$ can be determined by expression (6) via Newton iterative method. The relationship between $\delta_0$ and $F_y$ can be obtained, which is depicted in Figure 2.
is concerned in this model. The spindle-cutter system effects on machining precision, vibration only in machining plane (rear bearings. As the vibration in normal direction of an integral induction motor is located between the front and angular contact ball bearings. To drive this spindle system, in Figure 3. The rotor of spindle is held up by two pairs of spindle-cutter coupling system.

Nonlinear dynamic model of spindle-cutter coupling system

The schematic of a certain spindle-cutter system is shown in Figure 3. The rotor of spindle is held up by two pairs of angular contact ball bearings. To drive this spindle system, an integral induction motor is located between the front and rear bearings. As the vibration in normal direction of machining plane (−x direction shown in Figure 4) has effects on machining precision, vibration only in −x direction is concerned in this model. The spindle-cutter system is simplified to a five degree-of-freedom dynamic system as shown in Figure 4.

Where \( m_1, m_2, \) and \( m_3 \) are discrete masses constituting the spindle; \( m_4 \) and \( m_5 \) are discrete masses constituting the milling cutter; \( f_1 \) and \( f_2 \) are support forces from bearings; \( F_x \) is the interaction in −x direction between the spindle and tool holder, which can be determined by the method in the second section; \( F_c \) is the radial cutting force; \( k_1 \) and \( k_2 \) are the stiffness of spindle; \( k_3 \) is the stiffness of milling cutter; \( c_1 \) and \( c_2 \) are material damping of spindle; \( c_3 \) is material damping of milling cutter.

In this research, the equivalent mass \( (m_i(i = 1, 2, \ldots, 5)) \) and equivalent stiffness \( (k_i(i = 1, 2, 3)) \) are identified by the equivalent method in the literature. The material damping is assumed to be proportional to the corresponding stiffness and \( c_i = \frac{0.001}{m_i}k_i(i = 1, 2, 3) \).

According to the second Newton’s law, dynamic differential equation of the spindle-cutter system is formulated as follows:

\[
\begin{align*}
F_x &= \int_{-\infty}^{\infty} \sigma \cos \varphi \cos \theta dS = 2 \int_{0}^{\infty} \sigma \cos \varphi \cos \theta d\theta dy \\
F_c &= m_1 \ddot{x}_1 + c_2 \dot{x}_1 + k_2 x_1 - k_3 x_2 - c_3 \dot{x}_2 = m_1 g - f_1 \\
&+ m_2 \ddot{x}_2 + (c_1 + c_2) \dot{x}_2 + (k_1 + k_2) x_2 - k_3 x_2 - k_4 x_3 \\
&+ c_4 \dot{x}_4 + c_5 \dot{x}_5 + k_4 x_3 - k_5 x_4 - c_6 \dot{x}_5 = m_2 g - f_2 + F_x \\
&+ m_3 \ddot{x}_3 + c_1 \dot{x}_3 + k_3 x_3 - k_1 x_2 - c_2 \dot{x}_2 = m_3 g - f_2 + F_x \\
&+ m_4 \ddot{x}_4 + c_3 \dot{x}_4 + k_3 x_4 - k_5 x_5 - c_5 \dot{x}_5 = m_4 g - F_x \\
&+ m_5 \ddot{x}_5 + c_5 \dot{x}_5 + k_3 x_5 - k_4 x_4 - c_4 \dot{x}_4 = m_5 g - F_c
\end{align*}
\]

where \( x_1, x_2, x_3, x_4, \) and \( x_5 \) are displacements of nodes in −x direction corresponding to mass shown in Figure 4, and the downward direction is the positive direction. \( x_4-x_3 \) is equivalent to \( \theta' \), which is depicted in the second section. \( e \) is the offset of spindle, \( e = 3.21 \times 10^{-4} \text{mm} \). \( g \) is the gravity acceleration.
The support force of angular contact bearing can be written as:

\[
\begin{align*}
    f_1 &= 17.7236 \times 10^6 \times x_1 \sqrt{2} D F \frac{\cos^2 \alpha}{\sqrt{\sin \alpha}} \\
    f_2 &= 17.7236 \times 10^6 \times x_3 \sqrt{2} D F \frac{\cos^2 \alpha}{\sqrt{\sin \alpha}}
\end{align*}
\]

where \( z \) is the number of balls, \( D \) is the diameter of ball, \( F \) is the preload, and \( \alpha \) is the contact angle of bearing.

**Results and discussion**

Dimensionless variables

\[
\begin{align*}
    \frac{x_1}{e} &= \tilde{x}_1, & \frac{x_2}{e} &= \tilde{x}_2, & \frac{x_3}{e} &= \tilde{x}_3, & \frac{x_4}{e} &= \tilde{x}_4, & \frac{x_5}{e} &= \tilde{x}_5, \\
    \frac{x_1}{\omega} &= \tilde{x}_1, & \frac{x_2}{\omega} &= \tilde{x}_2, & \frac{x_3}{\omega} &= \tilde{x}_3, & \frac{x_4}{\omega} &= \tilde{x}_4, & \frac{x_5}{\omega} &= \tilde{x}_5, \\
    \frac{x_1}{e} &= X_1, & \frac{x_2}{e} &= X_2, & \frac{x_3}{e} &= X_3, & \frac{x_4}{e} &= X_4, & \frac{x_5}{e} &= X_5, & \tau &= \omega t
\end{align*}
\]

are introduced to normalize equation (8).
The dimensionless equation of spindle-cutter system is a set of ordinary differential equations with nonlinear and non-smooth excitation. For this equation, the analytical method to study nonlinear dynamic characteristic is difficult. The fourth-order Runge–Kutta method is adopted to solve equation (10). The relatively shorter time step is chosen to reduce the calculation error; meanwhile, a certain periods are abandoned to obtain stable transient solution of the system at the beginning of calculation.24 In this research, the time step \( \pi/1000 \) is chosen and the first 530 periods are abandoned.
Effects of drawbar force

To discuss the effect of drawbar force on nonlinear dynamic characteristic of the system, responses of cutter tip under different drawbar forces (i.e. $F_y = 4000\text{N, }1000\text{N, and }400\text{N}$) with the same rotational speed ($\omega = 20, 044\text{r/min}$) and no cutting force are compared in Figure 5.

The comparison highlights that Poincare section when $F_y = 4000\text{N}$ is a single point. It is a periodic motion and has only one peak in a period. Poincare section when
$F_y = 1000\text{N}$ has two points. It is a double period motion. Poincare section when $F_y = 400\text{N}$ is also a single point. It is a periodic motion and has six peaks in a period. The conclusion can be drawn that the drawbar force has effect on the vibration mode of cutter tip. There is little variation in the equilibrium position and amplitude of vibration.

**Effects of rotational speed**

To investigate the vibration of cutter tip in cutting process, the cutting force must be considered. The transient cutting force is determined by the method described in the literature.\textsuperscript{25} Through the comparison between the vibration with cutting force and that without cutting force, the conclusion can be drawn that the cutting force changes the vibration mode of cutter tip, and the vibration without cutting force is a periodic motion, whereas the vibration with cutting force turns to be chaotic.

To study the effect of rotational speed on nonlinear dynamic characteristic of the system, responses of cutter tip under different rotational speeds (i.e. $\omega = 20, 044\text{r/min, 21, 963r/min, and 25, 306r/min}$) with the same drawbar force ($F_y = 4000\text{N}$) considering cutting force are compared in Figure 6.

According to the response described in Figure 6, each Poincare section has many disordered points. It is a chaotic motion. The nonlinearity of the contact stiffness of spindle–tool holder should be avoided to ensure a stable cutting. The contact stress at the interface under the action of drawbar force and cutting force should be positive according to expression (5). Therefore, expression (11) is satisfied.

$$\delta_0 - \delta - \delta' \cos \theta > 0 \quad (11)$$

By solving expression (11), the relationship of rotational speed and critical drawbar force is obtained as depicted in Figure 7. When the rotational speed is selected, the critical drawbar force is determined. The drawbar force $F_y$ should be greater than the critical value.

**Conclusions**

A nonlinear model for determining contact stiffness at spindle–tool holder is proposed based on classic elasticity theory. On that basis, a nonlinear dynamic model of spindle
system under cutting force, which takes into account the nonlinearity of spindle–tool holder stiffness and cutting force, is established. Effects of drawbar force and rotational speed on transient response of cutter tip are discussed. The results of the numerical simulations indicate that the drawbar force has effect on the vibration mode of cutter tip. When the cutting force is considered, the motion of cutter tip turns to be chaotic. The proper rotational speed and drawbar force should be chosen to ensure a stable cutting according to the response of cutter tip.

Large amount of calculation is conducted during the solution of equation (5). The next stage of the research is how to decrease the amount of calculation.
