Materials

Acetic acid, urea, boric acid, ethylenediaminetetraacetic acid disodium salt dihydrate (EDTA), formamide, magnesium chloride hexahydrate, StainsAll®, tris(hydroxymethyl)aminomethane (Tris), N,N,N',N'-tetramethylethylenediamine, acrylamide, bis-acrylamide, ammonium persulfate and glycerol were used as purchased from Sigma Aldrich. 1000Å nucleoside-derivatized LCAA-CPG solid supports with loading densities of 25-40 µmol/g, reagents used for automated DNA synthesis were purchased from BioAutomation. Sephadex G-25 (super fine DNA grade) was used as purchased from Amersham Biosciences. 1 X TA-Mg\(^{2+}\) buffer was composed of 45 mM Tris, 7.6 mM MgCl\(_2\), with pH adjusted to 8.0 using glacial acetic acid. 1 X TBE buffer was composed of 90 mM Tris and boric acid, 1.1 mM EDTA, with a pH of ~ 8. Gold nanoparticles with a mean diameter of 5 nm and stabilized in citrate buffer, Bis(p-sulfonatophenyl)phenylphosphine dihydrate dipotassium salt (BSPP) and tris(2-carboxyethyl)phosphine (TCEP) were purchased from Sigma Aldrich. Cy3 or Cy5-labeled DNAs were purchased from Sangon Biotech Shanghai. All other regular DNA strands were purchased from Integrated DNA Technologies.

Instrumentation

Fluorescence measurements were conducted on HORIBA JobinYvon™ FluoroMax-4 spectrofluorometer. Standard solid-phase oligonucleotide synthesis was performed on BioAutomation MerMade MM6 DNA synthesizer. UV-Vis measurements were carried out on NanoDrop 1000 spectrophotometer. PAGE Gel electrophoresis experiments were carried out on a polyacrylamide 20 X 20 cm Maxi Vertical electrophoresis apparatus (MV-20DSYS). Agarose gel electrophoresis was performed on Bio-Rad Mini-Sub Cell GT Cell Apparatus with a 7 X 7 cm gel tray. Thermal denaturation was performed on Cary 300 UV-Vis Spectrophotometer. Matrix-Assisted Laser Deposition-Ionization Time-of Flight Mass Spectrometry (MALDI-TOF MS) was performed on Bruker Autoflex Mass Spectrometer.
DNA sequences

(a) General Procedures for Solid-Phase DNA Synthesis:

DNA synthesis was performed on 1 µmole scale, starting from the required nucleotide modified 1000 Å LCAA-CPG solid support. The vertex molecule, 2-cyanoethyl (4''-(trityloxy)-[1,1':3',1''-terphenyl]-4-yl) diisopropylphosphoramide was site-specifically coupled onto the growing oligonucleotide chain with a prolonged coupling time of 10 min and 3 couplings. The coupling efficiency was monitored by the removed trityl concentration level. All sequences were fully deprotected in concentrated ammonium hydroxide solution at 55°C for over 8 h.

(b) Purification:

Crude DNA strands were purified on 15% polyacrylamide/8M urea polyacrylamide gels at a constant current of 30 mA for 2 h (0.5 h at 250V followed by 1.5 h at 500 V), using 1 X TBE buffer. After electrophoresis, the plates were wrapped in plastic film and placed on a fluorescent TLC plate and then illuminated with a UV lamp at 254 nm. The bands were excised quickly and the selected gel pieces were crushed and incubated in 12 mL of sterile water at 55 °C for over 12 h. DNA samples were concentrated to about 1mL, desalted using Sephadex G-25 column chromatography. Quantification is carried by UV/Vis analysis.
Figure S1 MALDI-TOF spectrum for (a) T1 of m/z calcd 14968.87 g/mol; found, 15009.9956 g/mol [M]+, (b) T2 of m/z calcd 14696.67 g/mol; found, 14725.3306 g/mol [M]+, and (c) T3 of m/z calcd 14772.67 g/mol; found, 14780.4757 g/mol[M]+

The appearance melting temperature \( T_m \) assay

The appearance melting temperature \( T_m \) of DNA tetrahedron was determined with thermal denaturation experiment performed on Cary 300 UV-Vis spectrophotometer. The DNA tetrahedron sample was formed with 4.40 μM of each of the component strand T1, T2, T3, L1, L2 and L3 in 1 X PBS buffer was heated at 1 °C/min from 15 °C to 80 °C with a 1 °C interval and hold for 1 min at each degree. This experiment was performed twice. The appearance melting temperature \( T_m \) was calculated by taking the first derivative of the melting curve.

Quantitation of gold nanoparticle-DNA monoconjugates

To confirm the band excised from the agarose gel containing only one DNA strand per AuNP, we conducted additional experiments to quantify the unlabeled DNA strand bound to gold nanoparticle by
measuring the UV absorbance at 260 nm and at 520 nm. The coverage quantification was based on a UV-visible spectroscopy method reported by Hutchison and coworkers\(^1\) and performed on NanoDrop 1000 spectrophotometer. KCN treatment is used to decompose the purified AuNP-L1, conjugates in order to eliminate the UV/vis absorbance at 260 nm from AuNP core which can interfere with the UV absorbance of DNA at 260 nm. Take AuNP-L1 as an example.

\[
A_{260 \text{ dAuNP-L1}} = A_{260 \text{ L1}} + A_{260 \text{ dAuNP}} \quad \text{equation (1)}
\]

\[
A_{260 \text{ L1}} = A_{260 \text{ dAuNP-L1}} - A_{260 \text{ dAuNP}} \quad \text{equation (2)}
\]

Firstly, to determine the concentration of AuNP in AuNP-L1 sample, the UV spectrum of AuNP-L1 conjugate before KCN treatment was measured with absorbance 0.227 at 520 nm, which corresponded to \(2.27 \times 10^{-7}\) mol/L. Next, AuNP-L1 was treated with potassium cyanide (KCN) solution at pH 12 for 8 h to decompose into KAu(CN)\(_2\) and L1 strands. The absorbance of this decomposed mixture \((A_{260 \text{ dAuNP-L1}})\) was measured at 260 nm and is found to be 0.073 which is contributed by both L1 strands and the decomposed AuNPs (equation 1).

Next, to determine the absorbance of AuNP core contributed at 260 nm after KCN treatment, calibration curve of the decomposed AuNPs was obtained. As we have performed identical operations in our previous research work with the same gold nanoparticles,\(^2\) we used the previously obtained calibration curve directly. From the decomposed AuNP absorbance-concentration calibration curve, the absorbance of AuNP core contributed at 260 nm:

\[
A_{260 \text{ dAuNP}} = 0.0269 + (2.27 \times 10^{-7})* 507500 = 0.1421
\]

From equation 2, the absorbance contributed by L1 at 260 nm:

\[
A_{260 \text{ L1}} = 0.227-0.1421 = 0.0849
\]

Meanwhile, different concentrations of SCS1-SH strand were prepared and their absorbance at 260 nm were also measured and plotted against corresponding DNA concentrations. A good linear regression of the calibration curve was also obtained. From the SCS1 absorbance-concentration calibration curve, we could get the DNA concentration:

\[
[L1-\text{SH}] = (0.0849-0.0003063)/41250 = 1.43 \times 10^{-7} \text{ mol/L}
\]

Then the number of DNA strand per gold nanoparticle:

\[
N = (1.43 \times 2 \times 10^{-7}) / (32.27 \times 10^{-7}) = 1.17
\]
The same procedure was performed to confirm that we have also obtained the DNA-AuNP mono-conjugate for both L2-SH and L3-SH. We found that the number of DNA strand per gold nanoparticle for L2-SH and L3-SH was 1.38 and 1.42 respectively.

**Figure S3.** Agarose gel electrophoresis analysis of the formation of AuNP-DNA monoconjugate. Lane 1: bare AuNPs; Lane 2-4: reaction mixture of AuNPs with L1-SH, L2-SH and L3-SH respectively.
Figure S4. Liquid AFM images of py-THDs.

Figure S5. Denaturing PAGE analysis of py-THD in FBS digestion test under different time points.

To determine the mean half-life, bands at 0 time point were identified and used as baseline to remove the background intensity. The decay rate ($\lambda$) and half-life ($t_{1/2}$) were derived as follows.

$$I = I_0 e^{-\lambda t}$$
\[ \tau = \frac{1}{\lambda}, \]

\[ t_{1/2} = \tau \ln 2 \]

\[ = 3.95 \text{ h} \]

where \( \tau \) is time constant, \( I_0 \) is the initial band intensity and \( I \) is the band intensity at time \( t \).

Theoretical height calculation

To facilitate the analysis of the physical parameters obtained from characterization on the DNA tetrahedron, it is necessary to discuss and clarify some geometrical parameters associated with standard tetrahedron model. This DNA tetrahedron constructed by our strategy could be considered as a standard tetrahedron with some negligible deviations. The edge length of the out-of-plane three edges might be slightly different from that of three edges of the bottom facet because the former edges took a ladder-like linear conformation while the latter edges are of standard B-form helix. To simplify data analysis, this DNA tetrahedron was treated as standard model with all edges identical in length.

Thus, if a standard tetrahedron has an edge length of L, then the height H could be calculated by equation 3:

\[ H = L \times \left( \frac{\sqrt{6}}{3} \right) \]  
equation 3

In our design, the edges of the tetrahedron consisted of 15 base pairs, thus, the edge length of the DNA tetrahedron should be around 5.1 nm. Therefore, the height H could be calculated as

\[ H = 5.1 \times \left( \frac{\sqrt{6}}{3} \right) = 4.16 \text{ nm}. \]
