Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Construct design, biophysical, and biochemical characterization of the fusion core from mouse hepatitis virus (a coronavirus) spike protein

Yanhui Xu, David K. Cole, Zhiyong Lou, Yiwei Liu, Lan Qin, Xu Li, Zhihong Bai, Fang Yuan, Zihe Rao, George F. Gao

Abstract

Membrane fusion between virus and host cells is the key step for enveloped virus entry and is mediated by the viral envelope fusion protein. In murine coronavirus, mouse hepatitis virus (MHV), the spike (S) protein mediates this process. Recently, the formation of anti-parallel 6-helix bundle of the MHV S protein heptad repeat (HR) regions (HR1 and HR2) has been confirmed, implying coronavirus has a class I fusion protein. This bundle is also called fusion core. To facilitate the solution of the crystal structure of this fusion core, we deployed an Escherichia coli in vitro expression system to express the HR1 and HR2 regions linked together by a flexible linker as a single chain (named 2-helix). This 2-helix polypeptide subsequently assembled into a typical 6-helix bundle. This bundle has been analyzed by a series of biophysical and biochemical techniques and confirmed that the design technique can be used for coronavirus as we successfully used for members of paramyxoviruses.

Keywords: Mouse hepatitis virus; Coronavirus; Spike (S) protein; Fusion core; 6-Helix bundle; Heptad repeat regions (HR1 and HR2)
carboxyl terminus of S2 and a hydrophobic signal peptide at the N-terminus of S1.

The S2 domain has an internal fusion peptide and two heptad repeat (HR) regions designated HR1 and HR2 [8,9]. HR2 is located close to the transmembrane region, and HR1 is some 170 amino acids of its upstream. The HR regions are found in fusion proteins of many different viruses and form an important characteristic of class I viral fusion proteins (there are two classes of the viral fusion proteins under the current classification) [10–13].

Typical class I viral fusion protein contains several notable features. It has a fusion peptide at the amino terminus that is thought to insert directly into the target membrane during the viral fusion process [12]. Carboxyl-terminal to the fusion peptide are two regions containing 4,3 hydrophobic (heptad) repeats, sequence motifs, which form a coiled-coil structure in the post-fusion state after series of the conformational changes of the fusion protein [12]. This coiled-coil structure is a stable, protease resistant core in the ectodomain of enveloped glycoprotein (or fusion protein), named as viral fusion core [12]. The fusion core complex consists of trimer of HR1/HR2 heterodimers, therefore, it is also called 6-helix bundle. The MHV fusion core complex has been confirmed biophysically and biochemically [14] but its crystal structure is yet to be elucidated. We previously developed a method to prepare this core complex for other viruses [15–17] by linking the HR1 and HR2 as a single chain. It was shown to be an effective method to prepare diffractable crystals for such a core complex. Here we deployed this method to MHV HR1/HR2 complex and indeed it shows that the single chain HR1/HR2 (detonated as 2-helix) could be prepared as a trimer of HR1/HR2 heterodimer suitable for good-quality crystal preparation.

Materials and methods

Prediction of the heptad repeat regions and construction of the expression vectors

The α-helix structure of the two HR regions of the S protein of MHV was predicted by LearnCoil-VMF program (http://nightingale.lcs.mit.edu/cgi-bin/vmf), which was specifically developed for identification of potential coiled-coil HR regions in viral fusion proteins by Kim and colleagues at Massachusetts Institute of Technology [18]. The protease K resistant regions of HR1 and HR2 have been identified by Bosch and colleagues [14]. The HR regions were chosen based on the prediction of LearnCoil-VMF and the previous published data [14]. The HR1 region used was derived from amino acids 968–1027 and HR2 from 1216 to 1253 as shown in Fig. 1.

The genes encoding the HR1 and HR2 regions of MHV were synthesized by PCR using eight synthesized primers according to the published sequences of murine coronavirus MHV strain A59 (Gene Bank No. M18379). The codon usage was optimized according to Escherichia coli expression preferences. HR1 and HR2 were connected by an eight amino acid linker (GGSGGSGG, Fig. 1. Schematic representations of MHV S protein and the construct used in this study. SS, signal sequence; TM, transmembrane domain; HR1 and HR2, heptad repeats 1 and 2. Cleavage site of S1 and S2 domains is shown. Amino acid sequences of the HR1 and HR2 regions are shown and the 2-helix construct is schematically represented.

Here we deployed this method to MHV HR1/HR2 complex and indeed it shows that the single chain HR1/HR2 (detonated as 2-helix) could be prepared as a trimer of HR1/HR2 heterodimer suitable for good-quality crystal preparation.
single letter abbreviation of amino acids) and a 6-His tag was introduced by PCR primers at the C-terminus to facilitate the protein purification. The choice of the eight amino acids as linker was based on our previous successful work on other viral fusion core [15–17]. The constructs were cloned into the NdeI and XhoI sites (introduced by synthetic PCR primers) of pET22b expression vector (Novagen). Under this construction strategy, two extra amino acids were created between the C-terminal end of the HR2 and 6-His tag. They are “Leu–Glu” for XhoI restriction cloning site (CTCGAG for nucleotides). This construct was named as MHV 2-helix (Fig. 1). The construction was verified by direct DNA sequencing.

The primers overlapped with each other for 12–18 nucleotide bases. The NdeI and XhoI restriction sites were introduced by primer F and P8 (as shown below in capitalized/italic denominators). The gene of MHV 2-helix was obtained by two-step PCR. Firstly, the eight synthetic primers (0.2 OD/afii9839) were mixed and the PCR reactions were run with the following conditions: denatured at 94 °C for 5 min and then 15 cycles of 94 °C, 0.5 min; 55 °C, 1 min; and 72 °C, 1 min. For the second PCR, the first PCR product was used as template and the new PCR product was amplified by using primers F and P8 at the following conditions: denatured at 94 °C for 5 min and then 32 cycles of 94 °C, 0.5 min; 55 °C, 1 min; and 72 °C, 1 min.

Protein expression, purification, and gel-filtration analysis

The recombinant pET22b plasmids (MHV 2-helix) were transformed into E. coli strain BL21 (DE3). A single colony of the E. coli BL21 (DE3) transformed with the positive plasmid was grown in 2× YT medium containing 100-µg/mL of ampicillin in a 37 °C incubator. When the culture density (OD600) reached 0.6–0.8, the culture was induced with 0.2 mM IPTG and continuously grown for an additional 10 h at 16 °C before the cells were harvested. Bacterial cells were homogenized by sonication in phosphate-buffered saline (PBS, 10 mM sodium phosphate, pH 7.4; 150 mM NaCl). The lysates were clarified by centrifugation at 18,000g for 20 min at 4 °C. The supernatants were loaded on Ni-NTA column (QIAGEN) that was equilibrated with PBS. The contaminated protein was washed with washing buffer (1 × PBS, 60 mM imidazole) over 10 column volumes and the target protein was eluted with elution buffer (1 × PBS, 500 mM imidazole) for five column volumes. The resultant protein 2-helix was concentrated to a proper concentration by ultra-filtration (10 kDa cut-off). Proteins were analyzed by 10% Tricine SDS–PAGE. Further purification, the concentrated 2-helix protein was loaded onto a Superdex 75 HR10/30 (Pharmacia Biotech) column with an Akta Purifier System (Pharmacia Biotech). The fractions of the peak were collected and analyzed by a 10% Tricine SDS–PAGE. The peak molecular mass was estimated by comparison with the protein standards run on the same column (see Table 1).

### Chemical cross-linking of the complex

The purified 2-helix protein after gel-filtration was dialyzed against cross-linking buffer (50 mM Hepes, pH 8.3; 100 mM NaCl) and concentrated to approximately 2 mg/mL by ultra-filtration (10 kDa cut-off). Protein content

| Table 1 | Purification process of the 2-helix protein |
|---------|------------------------------------------|
| Bacterial cells | Pelleted by centrifugation |
| Lysed by sonication | Collection of the supernatant |
| Collection of the supernatant | Ni-NTA column |
| Washed by PBS | Eluted by 500 mM imidazole |
| Gel-filtration on Superdex 75 | Collection of the peak |
centrations were determined by absorbance at 280 nm, assuming an A280 of 0.22 for a 1.0 mg/mL. The proteins were cross-linked with ethyleneglycol bis(succinimidyl-succinate) (EGS) (Sigma). The reactions were incubated for 1 h on ice at different concentrations of EGS (0, 0.1, 0.5, and 1.5 mM EGS) and quenched with 50 mM glycine. Cross-linked samples were analyzed by 10% Tricine SDS–PAGE under reducing conditions.

**Circular dichroism spectroscopic analysis**

Circular dichroism (CD) spectra were performed on a Jasco J-715 spectrophotometer. The working buffer was PBS (10 mM sodium phosphate, pH 7.3; 150 mM NaCl). Wavelength spectra were recorded at 25 °C using a 0.1-cm path-length cuvette. Thermodynamic stability was measured at 222 nm by recording the CD signals in the temperature range of 25–90 °C with a scan rate of 5 °C/min.

**Expression and preparation of selenomethionine derivative of the MHV 2-helix**

The selenomethionine derivative of the MHV 2-helix was expressed using *E. coli* BL21 (DE3) cultured in minimal media M9 containing 60 mg/L L-SetMet. When the culture optical density (OD600) reached 0.6, the further six amino acids (lysine, threonine, phenylalanine, leucine, isoleucine, and valine) were added to the culture. The culture was then induced with 0.2 mM IPTG and grown for an additional 10 h at 16 °C. Purification of the selenomethionene-incorporated MHV 2-helix was performed as that used for the native MHV 2-helix.

**Mass spectroscopy**

The purified and desalted 2-helix proteins (both native and SeMet-incorporated 2-helix) were exchanged into the buffer of 20 mM Tris–HCl, pH 8.0, and then analyzed by using Bruker Daltonics Biflex III MALDI-TOF mass spectrometer for the molecular mass of the polypeptide.

**Results and discussion**

**2-Helix polypeptide is expressed as a soluble protein**

Based on the prediction of the LearnCoil-VMF program and the work by Bosch et al. [14], the HR1 and HR2 regions of MHV-A59 have been chosen in this study (Fig. 1). The single-chain construct of the fusion core HR1/HR2 was made as 2-helix as described under Materials and methods. The schematic representation of this construct is shown in Fig. 1. As expected from our previous work on paramyxovirus fusion core 2-helix proteins [15–17], the MHV 2-helix polypeptide preparation from the *E. coli* expression system in this study was expressed in high level and soluble in the physiological condition, i.e., in the buffers of either PBS or pH 8.0, Tris (Fig. 2). This implies that the protein has most likely been folded correctly. The protein has been shown to be soluble in the concentration of up to 40 mg/mL.

**2-Helix polypeptide forms a stable coiled-coil complex: the 6-helix bundle**

The purified proteins were concentrated to about 10 mg/mL in PBS and analyzed by gel filtration and chemical cross-linking for estimation of the molecular mass. The MHV 2-helix protein was eluted between the corresponding positions of 52 and 14 kDa (Fig. 3). In comparison, the computed molecular mass of 2-helix (with 6× Histidine) is about 13 kDa, which indicates that the 2-helix might form oligomers (about 40 kDa). MALDI-TOF results showed that the 2-helix monomer is about 12.6 kDa with two possible charges (Fig. 4A). Subsequently, chemical cross-linking demonstrated that the 2-helix protein oligomer was, in fact, a trimer (Fig. 5) from the estimated molecular mass of the
cross-linked products. In addition, the content of trimer increased with the concentration increase of the chemical cross-linker. Clear trimer band with monomer could also be seen if the samples (reduced by SDS loading buffer) were not heated at 100 °C (Lane 2 in Fig. 5A). All this indicates that the 2-helix protein forms a stable trimeric complex.

The secondary structure of the 2-helix protein was examined by CD spectroscopy as described under Materials and methods. The absorption curve showed that the 2-helix protein had double minima at 208 and 222 nm (Fig. 6A), consistent with typical α-helix structure. The thermal stability test by CD spectroscopy indicated that trimer formation of the 2-helix was very stable in PBS (Fig. 6B), indicating that the 2-helix trimer represents the core structure of the post-fusion state of the coiled-coil bundle, as thoroughly studied for other viral fusion proteins [10–12,19–21].

To facilitate the phase-determination of the 2-helix crystals, selenomethionine derivative preparations were made and the incorporation of the selenomethionine into the 2-helix preparation was confirmed by MALDI-TOF mass spectrometry (Fig. 4B). Moreover, it seems that the start-codon ATG-encoded methionine remains in the expressed 2-helix protein as the molecular increase between the native and SeMet derivative indicates that three methionines were replaced by SeMet (molecular mass increases by $3 \times (79 - 32) = 141$ Da). The crystal structure has now been solved at 2.4 Å and has been reported elsewhere [22].

---

Fig. 4. MALDI-TOF mass spectra of native and SeMet-labeled 2-helix proteins. The molecular mass of native 2-helix protein was 12,572 Da (A). The molecular mass of SeMet 2-helix protein was 12,709 Da (B). The molecular mass difference between (A) and (B) shows three Se molecules were incorporated. The two peaks in both cases indicate that the proteins carry two charges.
Conclusion

Our results do show that the strategy we used for other enveloped viruses, such as paramyxoviruses [15–17], to analyze the fusion core in the form of single chain HR1 and HR2, can be used for coronavirus. Coronavirus does most likely adapt to the similar fusion mechanism to other viruses with a class I fusion protein. A clear crystal structure of this fusion core from a member of coronavirus is now known and has answered some important questions [22].
