Abstract

Background

Cardiopulmonary exercise testing (CPET) and pulmonary function testing (PFT) are noninvasive methods to evaluate the respiratory and circulatory systems. This research aimed to evaluate and monitor chronic thromboembolic pulmonary hypertension (CTEPH) noninvasively and effectively. At the same time, assess the predictive value of CPET and PFT parameters for the aggravation of CTEPH.

Methods

We used data from 86 CTEPH patients (55 for test set, and 31 for validation set) at the Shanghai Pulmonary Hospital Affiliated to Tongji University. The clinical, PFT and CPET parameters of mild, moderate and severe CTEPH patients classified according to PAP (mm Hg) were compared. Logistic regression analysis was performed to appraise the predictive value of each potential predictor for severe CTEPH. The performance of PFT and CPET parameters for predicting severe CTEPH was determined by receiver operating characteristic (ROC) curves and calibration curves.

Results

Data showed that Load @ Peak (W), FEV1/FVC (%), and VE @ AT (L/min) were independent risk factors for severe CTEPH classified according to PAP (mm Hg). Additionally, the efficacy of the use of Load @ Peak (W), FEV1/FVC (%) and VE @ AT (L/min) in identifying severe CTEPH was found to be moderate with area under the curve (AUC) of ROC curves of 0.736, 0.696 and 0.769, respectively. Furthermore, combination with Load @ Peak (W), FEV1/FVC (%) and VE @ AT (L/min) had a moderate utility value in identifying severe CTEPH with an AUC of 0.897.

Conclusion

Our data suggests that PFT and CPET parameters can noninvasively and effectively evaluate, monitor and predict the aggravation of CTEPH.

Background

Cardiopulmonary exercise testing (CPET) provides a unique and comprehensive evaluation of respiratory and circulatory systems by detecting the gas exchange and exercise load during exercise[1]. It is considered to be a gold standard noninvasive measure of cardiorespiratory fitness and exercise capacity[2]. CPET has been widely carried out in patients with pulmonary hypertension (PH), heart failure (HF), chronic obstructive lung disease (COPD), asthma, etc.[3-5]. It has been reported to be of significance in disease diagnosis, assessing efficacy of therapeutic interventions, and evaluation of prognosis. However, due to the variety of parameters, makes it difficult for clinicians to correctly interpret CPET parameters under different situations.

CTEPH’s pathological characteristics are organized thrombus and vascular remodeling ultimately leading to right ventricular failure[6]. Pulmonary endarterectomy (PEA), balloon pulmonary angioplasty (BPA) and PH-targeted medical therapy are the main therapies of CTEPH[6]. The diagnosis of CTEPH can be achieved by right heart catheterization (RHC), ventilation/perfusion scan (V/Q) and CT pulmonary angiography (CTPA)[7, 8].

Since CTEPH is a kind of progressive disease, it is imperative to assess risk that affects disease progression appropriately and accurately for appropriate timely intervention. It has already been reported that CPET may be used to estimate the severity of PH[9]. Abnormalities noted during CPET were consistent, characteristic and correlated well with primary pulmonary hypertension (PPH) patients’ NYHA class[10, 11]. Stepping on these, we set this study to examine the difference of CPET performance between patients’ with mild-moderate and severe CTEPH.

Methods

Ethical approval

The study protocol was reviewed and approved by the Ethics Committee of Shanghai Pulmonary Hospital. Written informed consent was obtained from each patient for inclusion into the study and prior to the performance of any study-related procedures.

All methods including CPET, PFT, RHC and blood test were carried out in accordance with relevant guidelines and regulations.

Patients

This study retrospectively enrolled 86 inpatients with CTEPH who were referred to Shanghai Pulmonary Hospital from November 2015 to December 2019. All patients were definitely diagnosed by RHC. Patients with mean pulmonary artery pressure (mPAP) ≥25 (mmHg) and pulmonary arterial wedge pressure (PAWP) ≤15 (mmHg) were considered to have CTEPH. They also should had performance of ventilation/perfusion scan or pulmonary angiogram which were consistent with thromboembolic disease. Patients were excluded from study if they had any evidence of the following: right-to-left cardiac shunt, coexisting lung diseases (identified clinically or on CT scan), FEV1/FVC%<65% and undergone pulmonary endarterectomy. Enrolled patients’ data including demographics, medication, NT-pro BNP, hemodynamics, PFT and CPET were collected. Ethical approval by the medical ethics committee of Shanghai pulmonary hospital was obtained.

CPET

CPET was performed on an electromagnetically braked cycle ergometer (Master Screen CPX, Jaeger crop, Hoechberg, Germany) by using a breath-by-breath system to record gas exchange data over 10-s intervals. The protocol was consisted of the rest phase of 3 minutes, the unloaded phase of 3 minutes, the
loaded phase in which the workload increased 10-25W/min, and the recovery phase of 5 minutes. The patients should pedal at 55-60 revolutions/min in the unloaded and loaded phase, and when they reached their maximum tolerance they could enter the recovery phase. Patients could stop at any time when they have fatigue, dyspnea, chest tightness and any other discomfort during the process.

Measurements included Load, minute ventilation (VE), carbon dioxide output (VCO₂), oxygen uptake (VO₂), oxygen pulse (VO₂/HR), end-tidal partial pressure for carbon dioxide (PETCO₂), end-tidal partial pressure for oxygen (PETO₂), heart rate (HR), breathing reserve (BR), respiratory exchange ratio (RER) and breathing frequency (BF). Anaerobic threshold (AT) which represents the beginning of anaerobic metabolism was determined by the V-slope method. VE/VCO₂ slope was obtained by linear regression analysis of the relation between VE and VCO₂. Oxygen uptake efficiency slope (OUES) was computed by a linear squares regression from the oxygen uptake on the logarithm of the minute ventilation according to the following equation: VO₂= ae+bgVE+b. Constant “a” is called the OUES. Oxygen uptake efficiency plateau (OUEP) was at 90 seconds of the highest consecutive values for VO₂ (mL/min)/VE (L/min).

Statistical analysis

Data were analyzed by using SPSS 22.0 and GraphPad Prism 6. The data are presented as mean ± SD, median (interquartile range), or n. One-way ANOVA test, Kruskal-Wallis test, Tukey’s multiple comparisons test, Dunn’s multiple comparisons test, Unpaired t test, Mann-Whitney U test, chi-square test, univariate logistic regression analysis and multivariate logistic regression analysis were used according to the corresponding situation. A two-tailed P<0.05 was considered significant.

Results

Characteristics of the CTEPH subjects

55 patients with CTEPH were involved in the test set. They were divided into “Mild”, “Moderate” and “Severe” groups according to PAP (mm Hg). Mild: 35>PAP (mm Hg)≥25; Moderate: 45>PAP (mm Hg)≥35; Severe: PAP (mm Hg)>45.

The characteristics of all groups were summarized in Table 1 and Figure 1. The “Severe” group had the highest NT-proBNP (pg/mL) value when compared with the “Mild” and “Moderate” groups (143.0(63.8, 286.7) vs. 648.5(266.3,32049) vs. 1082(642.0,2674) pg/mL; P=0.001). The PAP (mm Hg) value of the “Mild”, “Moderate” and “Severe” groups were significantly different (28.60±3.27 vs. 39.50±3.87 vs. 56.40±8.03 mm Hg; P=0.0001). Additionally, significant differences in PVR and RAP values among the three groups were noted. PVR (wood u) value for the “Mild”, “Moderate” and “Severe” groups (3.7±1.3 vs. 7.6±2.4 vs. 10.9±3.8 wood u; P=0.0001), and for RAP (mm Hg) value of the “Mild”, “Moderate” and “Severe” groups (0.5(0,4.5) vs. 1.0(0,1.3) vs. 4.0(2.0,7.0) mm Hg; P=0.001).

CPET and PFT performance differences in subjects with CTEPH

During CPET, several parameters were found to be different among the “Mild”, “Moderate” and “Severe” groups. They are listed as followed: Load @ Peak (W), VO₂ @ Peak (mL/Kg/min), VE @ AT (L/min), BR @ Rest (%), BR @ AT (%), VE/VCO₂ @ AT, VE/VCO₂ @ Peak, VO₂/VE @ AT, PETCO₂ @ Rest, PETCO₂ @ AT, PETCO₂ @ Peak, PETO₂ @ Rest, PETO₂ @ AT, PETO₂ @ Peak, VE/VCO₂ slope and LOWEST VE/VCO₂. Details are listed in Table 2, Table 3 and Figure 1.

Predictive value of the CPET and PFT parameters for the severe CTEPH

Furthermore, 55 patients with CTEPH in the test set were re-grouped into “Mild-Moderate” and “Severe” group to analyze predictors for severe CTEPH. All the parameters measured were analyzed with the univariate analysis for the severe CTEPH, and 21 parameters were found to have a P<0.05. They are listed as followed: VE @ AT (L/min), VO₂/VE @ AT, BR @ AT (%), LOWEST VE/VCO₂, VE/VCO₂ @ AT, PETCO₂ @ AT, PETCO₂ @ Peak, FEV₁/FVC (%), PETCO₂ @ Rest, Load @ Peak (W), VE/VCO₂ @ Peak, BR @ Rest (%),VO₂ @ Peak (mL/Kg/min), VCO₂ @ Peak, VE/VCO₂ slope, FEV₁ (% Pred), VE/VCO₂ @ Rest, BMI (kg/m²), NT-proBNP (pg/mL), VO₂/VE @ Peak and RER @ Peak. Considering the sample size, 11 parameters with the minimum P value were fitted into the multivariate analysis, including VE @ AT (L/min) (OR: 1.169, P=0.004), VO₂/VE @ AT (OR: 0.762, P=0.004), BR @ AT (%) (OR: 0.936, P=0.006), LOWEST VE/VCO₂ (OR: 1.129, P=0.006), VE/VCO₂ @ AT (OR: 1.100, P=0.008), PETO₂ @ AT (OR: 1.184, P=0.009), PETCO₂ @ Peak (OR: 0.859, P=0.009), FEV₁/FVC (% (OR: 0.900, P=0.010), PETCO₂ @ Rest (OR: 0.769, P=0.011), Load @ Peak (W) (OR: 0.961, P=0.011) and VE/VCO₂ @ Peak (OR: 1.068, P=0.014). By using multivariate logistic regression analysis, VE @ AT (L/min) (OR: 1.400, P=0.048), FEV₁/FVC (% (OR: 0.756, P=0.007) and Load @ Peak (W) (OR: 0.881, P=0.021) were significant independent predictors for the severe CTEPH. Details are listed in Table 4 and Figure 2.

Combining these three parameters, we got the prediction equation for the severe CTEPH which was Logit(P)=7.397+0.205*VE@AT-0.116*FEV₁/FVC-0.059*Load @ Peak. To evaluate the ability of the VE @ AT (L/min), FEV₁/FVC (%), Load @ Peak (W) and the prediction equation to differentiate severe from mild-moderate CTEPH, ROC curves and calibration curves were performed. Details are listed in Table 5 and Figure 3. It must be noted that the AUC of the prediction equation was better than that for each parameter, indicating that the equation based on three parameters yielded the highest AUC value and could significantly improve the prediction performance for severe CTEPH.

Additionally, we analyzed the prediction equation in the validation datasets to validate the results. Only 4 of 31 patients with CTEPH of the validation set were ambiguous, and the accuracy was 87.10%. Details are listed in Table 6.
Discussion

We retrospectively analyzed the clinical, hematological, PFT and CPET data of 86 patients with CTEPH. Part of the patients were randomly classified into the validation set (a total of 31), and the remaining 55 patients were classified into the test set. Patients with CTEPH were divided into “Mild”, “Moderate” and “Severe” groups according to PAP (mm Hg) detected by RHC. This was used for finding the parameters likely predicting severe CTEPH[12]. Through comparison, we can find that there are differences in the CPET performance of patients with different severity of CTEPH. For example, Load @ Peak (W) and VO$_2$ @ Peak (mL/Kg/min) decreased with the aggravation of CTEPH. VE (L/min) and BR (%) of patients with different severity of CTEPH differed only at the AT phase. VE/VCO$_2$, VO$_2$/VE, PETCO$_2$ (mm Hg) and PETO$_2$ (mm Hg) was different between “Mild” and “Severe” groups. After that, patients with CTEPH were regrouped into “Mild-Moderate” and “Severe” groups. By univariate analysis for analyzing risk factors for severe CTEPH, 21 parameters were found to have a P<0.05. While by multivariate analysis, only Load @ Peak (W), FEV1/FVC (%) and VE @ AT (L/min) were found to have a P<0.05. Combining these three parameters, we got a prediction equation with AUC of 0.997 (Sensitivity: 80.0%, Specificity: 85.0%). ROC curves and calibration curves proved the prediction equation was good in discrimination and calibration. Additionally, its application in the validation set further confirmed the efficiency.

CPET could be used for the detection of CTEPH in patients with suspected PH but normal echocardiography. The number of patients with undiagnosed CTEPH may be significantly higher[13]. Estimates suggest that up to a quarter of patients with CTEPH may have no history of previous pulmonary embolism[14]. Compared with healthy cohorts, patients with CTEPH had higher value of VO$_2$/VE @ AT, VE/VCO$_2$ @ AT, P(c-ET)CO$_2$ while lower value of PETCO$_2$ @ AT. P(c-ET)CO$_2$ was a diagnostic parameter of CTEPH with the highest sensitivity (85.7%) and specificity (88.2%)[13]. Ventilatory efficiency parameters including P(c-ET)CO$_2$, PETCO$_2$ decrease patterns, VD/VT @ Peak, VE/VCO$_2$ slope, VE/VCO$_2$ @ AT, OUES and OUE @ AT can help to distinguish CTEPH from idiopathic pulmonary arterial hypertension (IPAH)[15-18]. The lowest VE/VCO2 ratio best predicts CTEPH from the chronic PE patients[19]. Godinas et al reported that in distal CTEPH patients, higher VD/VT was associated with lower peak oxygen consumption and worse survival[20]. Qi Jin et al reported that after BPA, patients with inoperable CTEPH had significant improvement in CPET and PFT parameters including Load @ Peak, VO$_2$ @ Peak, OUES, FVC, FEV1 and MVV[21]. As we have seen, CPET can be used for the diagnosis/differential diagnosis, prognostic evaluation and treatment evaluation of CTEPH.

For the first time, we have evaluated the value of CPET in the process of CTEPH aggravation. Despite current evidence not supporting routine screening for CTEPH after pulmonary embolism, it’s in the best interest of the up to a quarter of CTEPH patients that have no history of PE at least have a noninvasive test like CPET to better understand disease progression. We hope that CPET can be used for routine monitoring of CTEPH patients in the future, and then the application of this formula can provide value for guiding the further examination and treatment of patients. Our study shows that patients with severe CTEPH, the Load @ Peak (W) and FEV1/FVC (%) value was lower while VE @ AT (L/min) was higher in patients with mild-moderate CTEPH. The prediction equation Logit(P)=7.397+0.205*VE @ AT-0.116*FEV1/FVC-0.059* Load @ Peak was effective and efficient in discriminating patients with severe CTEPH. Some of the limitations of this study are its patient sample size, non-randomized nature and single-center design and potential selection bias.

Range for "Mild": 35>PAP (mm Hg)≥25; range for "Moderate": 45>PAP (mm Hg) ≥35; range for "Severe": PAP (mm Hg) ≥45. The data are presented as mean ± SD, median (interquartile range), or n. Statistical analysis of characteristics of "Mild", "Moderate" and "Severe" was analyzed with One-way ANOVA test, Kruskal-Wallis test or chi-square test, and was presented as "P". WHO=World Health Organization; BNP=brain natriuretic peptide; PAP=pulmonary artery pressure; PAWP=pulmonary arterial wedge pressure; CO=cardiac output; CI=cardiac index; PVR=pulmonary vascular resistance; RAP=right atrial pressure; FVC=forced vital capacity; FEV1=forced expiratory volume in 1s; RV=residual volume; TLC=total lung capacity; SB DLCO=carbon monoxide diffusing capacity.

### Table 2. Comparison of the CPET parameters of CTEPH subjects of different severity.
| Variables                          | Rest | AT | Peak |
|-----------------------------------|------|----|------|
| Load (W)                          |      |    |      |
| Mild                              |      |    |      |
| Moderate                          |      |    |      |
| Severe                            |      |    |      |
| P                                 |      |    |      |
| OUES (L/min/ log(L/min))          | 1.3±0.5 | 1.0±0.3 | 1.0±0.4 | 0.067 |
| OUEP (mL/L)                       | 23.4(21.0,27.9) | 22.7(21.4,23.8) | 21.3(19.1,22.7) | 0.078 |
| VE/VCO₂ slope                     | 40.9(32.3,53.0) | 48.4(41.1,68.7) | 61.7(49.9,78.5) | 0.006 |
| LOWEST VE/VCO₂                     | 43.7±9.1 | 48.6±5.8 | 55.0±10.1 | 0.004 |

Range for “Mild”: 35>PAP (mm Hg)≥25; range for “Moderate”: 45>PAP (mm Hg)≥35; range for “Severe”: PAP (mm Hg)≥45. The data are presented as mean ± SD or median (interquartile range). Statistical analysis of characteristics of “Mild”, “Moderate” and “Severe” was analyzed with One-way ANOVA test or Kruskal-Wallis test, and was presented as “P”. OUES=oxygen uptake efficiency slope; OUEP=oxygen uptake efficiency plateau; VE=ventilation; VCO₂=carbon dioxide output.

Table 3. Comparison of the CPET parameters of CTEPH subjects of different severity.
Variables | Univariate analysis | Multivariate analysis
--- | --- | ---
| | OR | P | 95% CI | OR | P | 95% CI |
VE @ AT (L/min) | 1.169 | 0.004 | 1.051-1.300 | 1.400 | 0.048 | 1.004-1.954 |
VO₂/ VE @ AT | 0.762 | 0.004 | 0.632-0.917 | 1.468 | 0.406 | 0.594-3.626 |
BR @ AT (%) | 0.936 | 0.006 | 0.892-0.981 | 1.041 | 0.504 | 0.916-1.183 |
LOWEST VE/VCO₂ | 1.129 | 0.006 | 1.036-1.230 | 0.815 | 0.483 | 0.460-1.444 |
VE/VCO₂ @ AT | 1.100 | 0.008 | 1.025-1.180 | 1.354 | 0.399 | 0.670-2.735 |
PETO₂ @ AT (mm Hg) | 1.184 | 0.009 | 1.043-1.345 | 0.673 | 0.069 | 0.440-1.032 |
PETCO₂ @ Peak (mm Hg) | 0.859 | 0.009 | 0.767-0.963 | 0.378 | 0.056 | 0.139-1.027 |
FEV₁/FVC (%) | 0.900 | 0.010 | 0.830-0.975 | 0.756 | 0.007 | 0.616-0.928 |
PETCO₂ @ Rest (mm Hg) | 0.769 | 0.011 | 0.628-0.943 | 1.050 | 0.902 | 0.485-2.273 |
Load @ Peak (W) | 0.961 | 0.011 | 0.931-0.991 | 0.881 | 0.021 | 0.790-0.981 |
VE/VCO₂ @ Peak | 1.068 | 0.014 | 1.013-1.126 | 0.802 | 0.251 | 0.551-1.168 |

Table 5. Predictive value of single factor and multiple factors for severe CTEPH.

| Variables | AUC | 95% CI | P | Cutoff-point value | Sensitivity | Specificity | Youden index |
|---|---|---|---|---|---|---|---|
Load @ Peak (W) | 0.736 | 0.600-0.873 | 0.004 | 61.0 | 71.4% | 75.0% | 0.464 |
FEV₁/FVC (%) | 0.696 | 0.549-0.843 | 0.016 | 77.9 | 71.4% | 65.0% | 0.364 |
VE @ AT (L/min) | 0.769 | 0.630-0.908 | 0.001 | 29.5 | 65.7% | 85.0% | 0.507 |
Logit(P) | 0.897 | 0.816-0.978 | 0.000 | 0.658 | 80.0% | 85.0% | 0.650 |

AUC=area under curve; CI=confidence interval; FEV₁=forced expiratory volume in 1s; FVC=forced vital capacity; VE=minute ventilation.

Table 6. Characteristics of subjects with $P<0.658$ and $P>0.658$ calculated by the predication equation in validation set.
| Variables                          | P<0.658 | P>0.658 | P   |
|-----------------------------------|---------|---------|-----|
| Age (years)                       | 53.9±16.0 | 56.9±12.0 | 0.552 |
| Sex, n (female/male)              | 9/4     | 8/10    | 0.275 |
| Height (m)                        | 1.6±0.1 | 1.6±0.1 | 0.504 |
| Weight (kg)                       | 61.1±11.2 | 61.7±11.0 | 0.874 |
| Body mass index (kg/m²)           | 23.6±3.4 | 23.2±2.7 | 0.743 |
| WHO classification II/III/IV, n   | 7/6/0   | 5/12/1  | 0.273 |
| NT-proBNP (pg/mL)                 | 203.0(44.5,329.5) | 858.5(488.3,2182) | 0.002 |
| PAP (mm Hg)                       | 38.5±7.6 | 52.3±8.3 | <0.0001 |
| PAWP (mm Hg)                      | 6.2±2.7 | 8.0±2.7 | 0.081 |
| CO (L/min)                        | 4.9±1.1 | 4.2±0.8 | 0.037 |
| CI (L/min/m²)                     | 3.0±0.6 | 2.5±0.5 | 0.028 |
| PVR (wood u)                      | 6.7±2.0 | 10.8±3.0 | 0.0001 |
| RAP (mm Hg)                       | 3.2±2.8 | 6.6±4.3 | 0.022 |
| Load @ Peak (W)                   | 74.2±24.5 | 54.3±24.4 | 0.033 |
| FEV1/FVC (%)                      | 82.5±8.6 | 74.9±5.7 | 0.006 |
| VE @ AT (L/min)                   | 25.7±6.8 | 32.7±8.5 | 0.020 |

The data are presented as mean ± SD, median (interquartile range), or n. Statistical analysis of characteristics of "P<0.658" and "P>0.658" was analyzed with Unpaired t test, Mann-Whitney U test or chi-square test, and was presented as "P". WHO=World Health Organization; BNP=brain natriuretic peptide; PAP=pulmonary artery pressure; PAWP=pulmonary arterial wedge pressure; CO=cardiac output; CI=cardiac index; PVR=pulmonary vascular resistance; RAP=right atrial pressure; FVC=forced vital capacity; FEV1=forced expiratory volume in 1s; VE=minute ventilation.

**Figures**
Comparison of the parameters of CTEPH subjects of different severity. Range for "Mild": 35>PAP (mm Hg)≥25; range for "Moderate": 45>PAP (mm Hg)≥35; range for "Severe": PAP (mm Hg)≥45. The data are presented as mean ± SD or median (interquartile range). Statistical analysis of characteristics of "Mild", "Moderate" and "Severe" was first analyzed with One-way ANOVA test or Kruskal-Wallis test, and was followed by Tukey's multiple comparisons test or Dunn's multiple comparisons test was presented as *, ** or ***. BNP=brain natriuretic peptide; PVR=pulmonary vascular resistance; RAP=right atrial pressure; FEV1=forced expiratory volume in 1s; FVC=forced vital capacity; VO2=oxygen uptake; HR=heart rate; VE=minute ventilation; BR=breathing reserve; VCO2=carbon dioxide output; PETCO2=end-tidal partial pressure for carbon dioxide; PETO2=end-tidal partial pressure for oxygen.

| Parameter          | OR(95%CI)         | P     |
|--------------------|-------------------|-------|
| Load @ Peak (W)    | 0.881(0.931-0.991)| 0.021 |
| FEV1/FVC (%)       | 0.756(0.830-0.975)| 0.007 |
| VE @ AT (L/min)    | 1.400(1.051-1.300)| 0.048 |
Predictors of severe CTEPH on multivariable analysis of CPET and PFT parameters. Range for "Severe": PAP (mm Hg) ≥ 45. Results are expressed as odds ratio (OR) with 95% confidence interval (95% CI). FEV1 = forced expiratory volume in 1s; FVC = forced vital capacity; VE = minute ventilation.
