Abstract

This paper investigates the scheduling process for multi-area interconnected power systems under the shared but band-limited network and decentralized load frequency controllers. To cope with sub-area information and avoid node collision of large-scale power systems, round-robin and try-once-discard scheduling are used to schedule sampling data among different sub-grids. Different from existing decentralized load frequency control methods, this paper studies multi-packet transmission schemes and introduces scheduling protocols to deal with the multi-node collision. Considering the scheduling process and decentralized load frequency controllers, an impulsive power system closed-loop model is well established. Furthermore, sufficient stabilization criteria are derived to obtain decentralized $H_\infty$ output feedback controller gains and scheduling protocol parameters. Under the designed decentralized output feedback controllers, the prescribed system performances are achieved. Finally, a three-area power system example is used to verify the effectiveness of the proposed scheduling method.

Keywords: Multi-area power systems, round-robin scheduling, try-once-discard scheduling, load frequency control

1. INTRODUCTION

With the vigorous development of power markets, the degree of interconnection among power grid regions is increasing. At present, power grids have developed into multi-area interconnected power systems [1,2]. Generally, there are two communication schemes to transmit data between neighborhood areas, that is, the dedicated channel and the open infrastructure. Since the latter has outstanding advantages over the former, such
as higher flexibility and lower cost, it has been widely used in the communication of multi-area interconnected power systems [3–5].

An important indicator to measure power system operation quality is the fluctuation in frequency, and load frequency control (LFC) is widely used to maintain frequency interchanges at scheduled values and stifle frequency fluctuation caused by load disturbances [2, 6, 7]. Under the open communication infrastructure, the sensor in each area collects data information. Then, data is transmitted to the decentralized controller under the shared but band-limited network. The corresponding control commands are issued to actuators in each area respectively. However, due to the introduction of the network, the design and operation of LFC face some new challenges, such as node collision, data loss and network-induced delay [8–10].

Due to different locations of sub-region power grids and the wide distribution of system components, multi-channel transmission is inevitable in multi-area interconnected power systems, while most of the existing results [10–13] take the general assumption that sampled data is packaged into a single packet to transmit, which is not applied in large-scale multi-area interconnected power systems. On the other hand, the shared network has limited bandwidth, where the simultaneous transmission under multiple channels may cause node congestion. To solve this problem, scheduling protocols have been presented to decide which node to gain access to the communication network [15].

Generally, multi-channel scheduling includes Round-Robin (RR) scheduling [16, 17], try-once-discard (TOD) scheduling [18, 19], and stochastic scheduling [20]. Under the RR scheduling protocol, each node is transmitted periodically with a fixed period whose value is the total number of transmission channels. Under the TOD scheduling, the sensor node with the largest scheduling error has access to the channel. Recently, a time-delay analysis method has been discussed to derive stability criteria for networked control systems (NCSs) which are scheduled by the above three communication protocols [14, 21]. Besides, a hybrid system method has been employed to analyze NCSs with variable delays under the TOD communication protocol [19], where a partial exponential stabilization criterion has been derived. The $H_\infty$ filtering of NCSs with multiple nodes has been investigated [22], in which TOD protocol is used to schedule sampled data.

This paper studies the $H_\infty$ LFC for multi-area interconnected power systems with decentralized controllers under the shared but band-limited network. RR and TOD protocols are used to schedule the sampling information of different sub-grids, which could greatly improve communication efficiency. Through linear matrix inequality (LMI) technology and Lyapunov analysis methods, sufficient conditions that guarantee the prescribed $H_\infty$ performance of the studied system are derived. Decentralized controller gains and protocol parameters are obtained simultaneously. The main contributions are summarized as follows.

(1) RR and TOD protocols are used to deal with the multi-node collision of large-scale power systems, which improve communication efficiency greatly. Compared with the existing LFC methods [10, 23, 24], the scheduling process under multi-area transmission schemes is investigated.

(2) An networked power system impulsive closed-loop model is well constructed, which covers the multi-channel scheduling, packet dropout, disturbance, and network-induced delays in a unified framework. Compared with the system without disturbance [19], this paper studies the anti-disturbance performance of the studied system. An $H_\infty$ LFC method is presented to obtain decentralized controller gains and scheduling protocol parameters simultaneously.

1.1. Notations
Throughout this paper, $\mathbb{R}_n$ stands for the n-dimensional Euclidean space with vector norm $\| \cdot \|$. $\text{diag} \{ \cdot \}$ and $\text{col} \{ \cdot \}$ denote the block-diagonal matrix and block-column vector, respectively. The superscript $T$ stands for
the transpose of a matrix or a vector. \( I \) is an identity matrix with an appropriate dimension. Matrix \( X > 0 (X \geq 0) \) means that \( X \) is a positive definite (positive semi-definite) symmetric matrix. The symbol * is the symmetric term in a matrix. \( w[-h, 0] \) denotes the Banach type of absolutely continuous functions \( \phi : [-h, 0] \rightarrow \mathbb{R}^n \) with \( \phi^* \in L_2(-h, 0) \) with the norm \( \| \phi \|_{\infty} = \max_{v \in [-h, 0]} \| \phi(v) \| + \left[ \int_{-h}^{0} \| \phi'(v) \|^2 dv \right]^{\frac{1}{2}}. \)

2. PROBLEM FORMULATION

Considering single-packet size constraints, the dynamic model of multi-area interconnected power systems with decentralized load frequency controllers is constructed in this section. An impulsive system model under TOD or RR protocol is established.

2.1. Multi-area decentralized LFC model

Diagram of the multi-area decentralized LFC under scheduling protocols is shown in Figure 1, where data transmission from sensors to decentralize controllers is scheduled by RR or TOD scheduling protocol.

The system model is represented as \(^{[23,25]}\):

\[
\begin{align*}
\dot{x}(t) &= Ax(t) - Bu(t) + D\omega(t), \\
y(t) &= Cx(t),
\end{align*}
\]

where \( x(t) \in \mathbb{R}_n \) is the state vector, \( y(t) \in \mathbb{R}_{m_y} \) is the measurement and \( \omega(t) \in \mathbb{R}_{m_\omega} \) is the disturbance, \( u(t) \in \mathbb{R}_{n_u} \) is the control input vector. The multi-area power systems consist of generators, turbines, and governors, where \( \Delta P_{vi}, \Delta P_{mi}, \Delta P_{di}, \) and \( \Delta f_i \) denote the deviation of valve position, generator mechanical output, load, and the frequency of the \( i \)th sub-area, respectively. The area control error \( ACE_i(s) \) is

\[
ACE_i(s) = \beta_i \Delta f_i(s) + \Delta P_{tie-i}(s).
\]

The state and measured output signals are

\[
\begin{align*}
x^T_i(t) &= [\Delta f_i(t), \Delta P_{tie-i}(t), \Delta P_{mi}, \Delta P_{vi}, \int ACE_i(t)] \\
\omega_i(t) &= \Delta P_{di}(t), \\
y^T_i(t) &= [ACE_i(t), \int ACE_i(t)]
\end{align*}
\]

where \( x(t) = [x_1^T(t), \cdots, x_n^T(t)]^T, y(t) = [y_1^T(t), \cdots, y_n^T(t)]^T \in \mathbb{R}_n, \omega(t) = [\omega_1^T(t), \cdots, \omega_n^T(t)]^T, A = \]

\[
\begin{align*}
\dot{x}(t) &= Ax(t) - Bu(t) + D\omega(t), \\
y(t) &= Cx(t),
\end{align*}
\]
\[ A_{ij} = \begin{bmatrix}
\frac{-D_j}{M_j} & 0 & 0 & 0 \\
\frac{1}{M_i} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}, \quad i = 1, \cdots, N, \quad j = 1, \cdots, i - 1, \cdots, N.
\]

\[ F_i = \begin{bmatrix}
\frac{1}{M_i} \\
0 \\
0 \\
0 \\
\end{bmatrix}, \quad B_i = \begin{bmatrix}
0 \\
0 \\
\frac{1}{T_{gi}} \\
0 \\
\end{bmatrix}, \quad C_i = \begin{bmatrix}
\beta_i \\
0 \\
0 \\
0 \\
\end{bmatrix}.
\]

The multi-area power system includes \( N \) controlled areas, \( N \) decentralized controllers, which are connected via the network. Then, measurement signals are given by

\[ y_i(t) = C_i x(t) \in \mathbb{R}_{n_i}, \quad i = 1, \cdots, N, \quad \sum_{i=1}^{N} n_i = N. \]

Based on the phasor measurement unit, sampling instants of \( N \) sensors are synchronized in different areas of power systems. Denote sampling instant by \( s_q \), satisfying that

\[ 0 = s_0 < s_1 < \cdots < s_q < \cdots, \quad s_{q+1} - s_q \leq \varrho, \quad \lim_{q \to +\infty} s_q = +\infty, \]

where \( \varrho \) is the maximum allowable transfer interval.

In this paper, we take imperfect network conditions into account, such as data loss and network-induced delay. Denote the sequence after packet loss by \( \{ s_k \} \subseteq \{ s_q \} \); that is, only at sampling instants \( s_k \), the input of the controller can be updated. For \( i = 1, \cdots, N \), an uncertain, time-varying delay \( \tau_{s_k}^i \in [0, \tau_M^i] \) is assumed to occur, where \( \tau_M^i \) is delay upper bound of the \( i \)th channel and \( \max_{i=1,\cdots,N} \tau_M^i = \tau_M \). Buffers are set to store and choose the largest communication delay \( \tau_{s_k} \) of power system channels, i.e., \( \tau_{s_k} = \max_{i=1,\cdots,N} \tau_{s_k}^i \). Then, ZOH updating instant is \( t_k = s_k + \tau_{s_k} \). The transmission delay is assumed to be bound, satisfying:

\[ 0 \leq \tau_{s_k} \leq \tau_M, \quad t_{k+1} - t_k - \tau_{s_k} \leq \tau_M + \varrho = \bar{\tau}. \]

Let \( \hat{y}(s_k) = [\hat{y}_1^T(s_k) \cdots \hat{y}_N^T(s_k)]^T \in \mathbb{R}_{n_i} \) denote the output signal transmitted to the scheduler. At instant \( s_k \), only one node can be active. Let \( t_k \in \{1, \cdots, N\} \) be the active output node at \( s_k \), which is dependent on the scheduling rule. Then, we have

\[ \hat{y}_i(s_k) = \begin{cases} y_i(s_k), & i = t_k \\ \hat{y}_i(s_{k-1}), & i \neq t_k \end{cases} \]

Consider the scheduling error between output \( y_i(s_k) \) and the last available measurement \( \hat{y}_i(s_{k-1}) \):

\[ e_i(t) = -y_i(s_k) + \hat{y}_i(s_{k-1}), \quad e(t) = \text{col} \{ e_1(t), \cdots, e_N(t) \}, \quad t \in [t_k, t_{k+1}) \]

where \( \hat{y}_i(s_{-1}) \triangleq 0 \), \( i = 1, \cdots, N \). In this paper, controllers and actuators in the \( i \)th area are event-driven. Let \( L_i > 0, i = 1, \cdots, N \) be node weighting matrices. Under TOD scheduling,

\[ t_k = \arg \max_{i \in \{1, \cdots, N\}} \sqrt{L_i (\hat{y}_i(s_k) - \hat{y}_i(s_{k-1}))} \]

Under RR scheduling protocol, the active node \( t_k \) is selected periodically:

\[ t_k = t_{k+N}. \]
In the following, we will design the decentralized LFC law under the communication network. Similar to\textsuperscript{[23]}, a PI controller is used in this paper:

$$u_i(t) = -K_{pi}ACE_i(t) - K_{hi} \int ACE_i(t).$$  

(8)

Therefore, dynamic model of the scheduled power systems under the decentralized LFC Equation (8) and imperfect network environments can be formalized as

$$\left\{\begin{array}{l}
\dot{x}(t) = Ax(t) - BK\dot{y}(s_k) + Fw(t) \\
y(t) = Cx(t), t \in [t_k, t_{k+1}),
\end{array}\right.$$  

(9)

where $u(t) = \sum_{i=1}^{N} K_i y_i(t) = Ky(t), K = [K_1, \ldots, K_N], K_i = [K_{pi}, K_{hi}].$

2.2. Impulsive model and study objective

From Equation (5), one can obtain that

$$e_i(t_{k+1}) = \begin{cases} 
C_i x(s_k) - C_i x(s_{k+1}), & i = t_k \\
C_i [x(s_k) - x(s_{k+1})] + e_i(t_k), & i \neq t_k
\end{cases}$$  

(10)

Define an artificial delay $\tau(t) = t - s_k$, from which one arrives at

$$0 \leq \tau_{s_k} \leq \tau(t) \leq s_{k+1} - s_k + \tau_{s_{k+1}} \leq \tau_M, \quad \tau(t) = 1.$$  

(11)

From Equation (5) and Equation (9), the impulsive power system model can be

$$\dot{x}(t) = Ax(t) - BK C x(t - \tau(t)) - \sum_{i=1, i \neq t_k}^{N} BK C_i e_i(t) + Fw(t).$$  

(12)

For system Equation (12), the initial condition of $x(t)$ on $[-\tau_M, 0]$ is supplemented as $x(t) = \phi(t), t \in [-\tau_M, 0]$, with $\phi(0) = x_0$, where $\phi(t)$ is a continuous function on $[-\tau_M, 0]$.

Using scheduling scheme Equation (6) and Equation (7), this paper is to design the decentralized controller Equation (8) such that system Equation (12) is exponentially stable with a prescribed $H_{\infty}$ performance $\gamma$.

3. MAIN RESULTS

In the following, we first derive sufficient criteria under scheduling scheme Equation (6) and Equation (7) to ensure the exponential stability of system Equation (12) with a prescribed $H_{\infty}$ performance. Then, criteria are proposed to design decentralized controllers under multi-channel transmission.

3.1. Stability analysis under the TOD scheduling scheme Equation (6)

Construct Lyapunov-Krasovskii functional candidate:

$$V(t) = \sum_{i=1}^{N} e_i^T(t) L_i e_i(t) + \Pi(t) + V_H,$$  

(13)

where $O > 0, H_i > 0, T > 0, L_i > 0, \alpha > 0, S > 0, i = 1, \ldots, N, t \in [t_k, t_{k+1})$,

$$V_H = \sum_{i=1}^{N} \int_{s_k}^{t} \tau_M e^{2\alpha(t-s)} \|\sqrt{H_i} \dot{x}(s)\|^2 ds,$$

$$\Pi(t) = \int_{t-\tau_M}^{t} e^{2\alpha(t-s)} \dot{x}(s) X(s) ds + X(t) O x(t) + \tau_M \int_{t-\tau_M}^{t} \int_{s}^{t} e^{2\alpha(t-s)} \dot{x}(v) T \dot{x}(v) dv ds.$$
Remark 1 \( V_H \) is introduced to cope with reset conditions, which is continuous on \([t_k, t_{k+1})\), and does not grow in the jumps when \( t = t_{k+1} \) since

\[
-V_H(t_{k+1}) + V_H(t_{k+1}) \leq - \sum_{i=1}^{N} e^{-2\alpha \tau_M} \| \sqrt{\mathcal{H}} H_i (e^{-x(s_{k+1})} + x(s_k)) \|^2
d\]

Theorem 1 Under TOD scheduling scheme Equation (6), for given scalars \( \tau_M, \alpha > 0, \gamma > 0 \), impulsive system Equation (12) is exponentially stable with a prescribed \( \mathcal{H}_\infty \) performance \( \gamma \), if there exist appropriate dimensions \( Y \) and real matrices \( O > 0, S > 0, T > 0, H_i > 0, J_i > 0, \) \( i = 1, \cdots, N \) such that

\[
\begin{bmatrix}
\xi_{11} & * & * \\
\xi_{21} & \xi_{22} & * \\
\xi_{31} & 0 & \xi_{33}
\end{bmatrix} < 0, \tag{15}
\]

\[
\left[
\begin{array}{c}
T \\
Y \\
T
\end{array}
\right] > 0, \tag{16}
\]

\[
\Omega_i = \begin{bmatrix}
\Omega_{i1} & \Omega_{i2} \\
* & \Omega_{i2}
\end{bmatrix} < 0 \quad \text{for } i, j = 1, \cdots, N, \tag{17}
\]

are feasible for \( i, j = 1, \cdots, N \), where

\[
\xi_{11} = \begin{bmatrix}
\Psi_{11} & \Psi_{12} & \Psi_{13} & \Psi_{14} & \Psi_{15} \\
* & \Psi_{22} & \Psi_{23} & 0 & 0 \\
* & * & \Psi_{33} & 0 & 0 \\
* & * & * & \Psi_{44} & 0 \\
* & * & * & * & \Psi_{55}
\end{bmatrix}, \tag{18}
\]

\[
\phi_i = \begin{cases}
\text{diag}\{\psi_2, \cdots, \psi_N\}, t_k = 1 \\
\text{diag}\{\psi_1, \cdots, \psi_{N-1}\}, t_k = N \\
\text{diag}\{\psi_1, \cdots, \psi_{j\neq k}, \cdots, \psi_N\}, t_k \neq 1, N
\end{cases}, \quad \pi_i = \begin{cases}
\{BK_2C_2, \cdots, BK_NC_N\}, t_k = 1 \\
\{BK_1C_1, \cdots, BK_{N-1}C_{N-1}\}, t_k = N \\
\{BK_1C_1, \cdots, BK_{j\neq k}, \cdots, BK_NC_N\}, t_k \neq 1, N.
\end{cases}
\]

Proof: Differentiating \( V(t) \) along Equation (12) and applying Wirtinger-based integral inequality\cite{26}, we can obtain

\[
\dot{V}(t) + 2\alpha V(t) - \frac{1}{\tau_M} \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} C_i e_i(t)|^2 - 2\alpha |L_i e_i(t)|^2 + |y(t)|^2 - \gamma^2 |\omega(t)|^2 \leq -\frac{1}{\tau_M} \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} C_i e_i(t)|^2
\]

\[
- \gamma^2 |\omega(t)|^2 - e^{-2\alpha \tau_M} x^T(t - \tau_M) S x(t - \tau_M) + |y(t)|^2 + x^T(t) \Omega x(t) - e^{-2\alpha \tau_M} T \int_{t - \tau_M}^{t} x^T(s) T x(s) ds \tag{18}
\]

\[
+ 2\alpha \sum_{i=1, j \neq i}^{N} e_i^T(t) C_i L_i C_i e_i(t) + 2x^T(t) O \dot{x}(t) + x^T(t) (2\alpha O + S) x(t),
\]

where \( \xi_i(t) = \text{col}\{x(t), x(t - \tau(t)), x(t - \tau_M), \dot{x}(t), \omega(t)\} \).
We use the reciprocally convex approach\cite{27} to deal with the cross item in Equation (18). By using Schur’s complement, one can get
\[
\dot{V}(t) + 2\alpha V(t) - \frac{1}{\tau_M} \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} e_i(t)|^2 - 2\alpha |\sqrt{L_{ik}} e_k(t)|^2 + |y(t)|^2 - \gamma^2 |\omega(t)|^2 < 0.
\] (19)

In the following, we will prove that

(i) with $\omega(t) = 0$, the impulsive system Equation (12) is exponentially stable.

Since $\frac{d}{dt} e^{2\alpha t}V(t) = e^{2\alpha t}(\dot{V}(t) + 2\alpha V(t))$ and $V(t)$ is continuous in $t \in [t_k, t_{k+1})$, the integration of Equation (19) yields
\[
e^{2\alpha t}V(t) - e^{2\alpha t_k}V(t_k) \leq \int_{t_k}^{t} e^{2\alpha s} ds \left[ 2\alpha |\sqrt{L_{ik}} e_k(t)|^2 + \frac{1}{\tau_M} \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} e_i(t)|^2 \right].
\] (20)

It follows from $\int_{t_k}^{t} e^{2\alpha (t-s)} ds \leq \tau_M$ that
\[
V(t_{k+1}) \leq \Theta_k + e^{2\alpha (t_k-t_{k+1})}V(t_k),
\] (21)

where
\[
\Theta_k = \sum_{j=1}^{N} \left[ -V_H(t_{k+1}) + |\sqrt{L_{ik}} e_k(t_{k+1})|^2 - |\sqrt{L_{ik}} e_k(t_k)|^2 + V_H(t_k) \right] + \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} e_i(t)|^2 + 2\alpha \tau_M |\sqrt{L_{ik}} e_k(t_k)|^2.
\] (22)

Then taking Equation (17) and Equation (22) into account, denoting $k_i = [e_i(t_k), C_i[-x(s_{k+1}) + x(s_k)]]^T$, we have
\[
\Theta_k \leq -||H_{ik} e^{-2\alpha \tau_M} - \sqrt{L_{ik}}||C_i [x(s_k) - x(s_{k+1})]|^2 + \sum_{i=1, j \neq i}^{N} k_i \Omega_k k_i \leq 0.
\] (23)

Hence, one can conclude that
\[
V(t) \leq \sum_{i=1, j \neq i}^{N} |\sqrt{J_i} e_i(t_k)|^2 + e^{2\alpha (t_0-t)}V(t_0) + 2\alpha \tau_M |\sqrt{L_{ik}} e_k(t_k)|^2.
\] (24)

From Equation (24), we have
\[
V(t) \geq \lambda_{\min}\{O\} |x(t)|^2 + \sum_{i=1}^{N} |\sqrt{L_{i}} e_{i}(t)|^2,
\]
which implies that
\[
\lambda_{\min}\{O\} |x(t)|^2 \leq (2\alpha \tau_M - 1)|\sqrt{L_{ik}} e_k(t_k)|^2 + \sum_{i=1, j \neq i}^{N} |\sqrt{J_i - L_{ik}} e_i(t)|^2 + e^{2\alpha (t_0-t)}V(t_0).
\]

It follows from $\Omega_k < 0$ that for $t \geq t_0$
\[
\lambda_{\min}\{O\} |x(t)|^2 \leq e^{2\alpha (t_0-t)}V(t_0).
\] (25)

For $t < t_0$, the system takes the form $\dot{x} = Ax(t) + F_\omega(t)$, then its corresponding solution is given by
\[
x(t) = e^{A t} x(0) + \int_{0}^{t} e^{A(t-s)} F_\omega(s) ds.
\] (26)
Clearly, there exists the maximum of $|x(t)|$ for $t \in [t_0 - \tau_M, t_0]$. Thus, $V(t_0) \leq \mu \|x(t_0)\|^2_W + \sum_{i=1}^{N} e_i(t_0)^2 L_i e_i(t_0)$ for some $\mu > 0$.

Therefore, the exponential stability of the system Equation (12) with $\omega(t) = 0$ is guaranteed.

Next, we will show that

(ii) under the zero initial condition, the inequality $\|y\|_{L_2^2} \leq \gamma \|\omega\|_{L_2^2}$ holds for any nonzero $\omega \in L_2[0, +\infty)$.

From Equation (19), we obtain that for $t \in [t_k, t_{k+1})$,

$$|y(t)|^2 - \gamma^2 |\omega(t)|^2 \leq -\dot{V}(t) + 2\alpha |\sqrt{T_k} e_k(t)|^2 + \frac{1}{\tau_M} \sum_{j=1}^{N} e_j(t_0) L_j e_j(t_0).$$  \hspace{1cm} (27)

Integrating Equation (27) on $t$ from $t_k$ to $t_{k+1}$ yields

$$\int_{t_k}^{t_{k+1}} |y(s)|^2 - \gamma^2 |\omega(s)|^2 ds + V(t_{k+1}) \leq V(t_k) + \Theta_k \leq V(t_k).$$  \hspace{1cm} (28)

Then, by summing Equation (28) on $k$ from 0 to $\rho$, where $\rho \to +\infty$, we have

$$\int_{t_0}^{\rho+1} (|y(s)|^2 - \gamma^2 |\omega(s)|^2) ds \leq V(t_0).$$  \hspace{1cm} (29)

Under the zero initial condition, $\int_0^{+\infty} y^T(s) y(s) ds \leq \int_0^{+\infty} \gamma^2 \omega^T(s) \omega(s) ds$. Therefore, one can derive that under the zero initial condition, $\|y\|_{L_2^2} \leq \gamma \|\omega\|_{L_2^2}$ for any nonzero $\omega \in L_2[0, +\infty)$. This completes the proof.

**Remark 2** The feasibility of the linear matrix inequalities has been sufficiently explained in [23,28]. Due to page limitations, this part is omitted here.

### 3.2. Stability analysis under the RR scheduling scheme Equation (7)

Construct the following Lyapunov-Krasovskii functional candidate:

$$V(t) = V_H + V_L, \quad k \geq N - 1, \quad t \in [t_k, t_{k+1}),$$  \hspace{1cm} (30)

where

$$V_H = \begin{cases} 
\sum_{i=1}^{N-1} \tau_M \int_{t_k}^{t} e^{2 \alpha (s-t)} |\sqrt{T_k} C_i \hat{x}(s)| ds, & k \neq N - 1, \\
\sum_{i=1}^{N-1} \tau_M \int_{t_0}^{t} e^{2 \alpha (s-t)} |\sqrt{T_k} C_i \hat{x}(s)| ds, & k = N - 1,
\end{cases}$$

$$H_i = (N - 1) L_i e^{2 \alpha (N-1) \tau_M}, V_L = \sum_{i=1}^{N-1} \frac{t_{k+1} - t}{i \tau_M} |\sqrt{T_k} e_i(t)|^2.$$  \hspace{1cm} (31)

Similar to Theorem 5.2 in [28], we establish the following result.

**Theorem 2** Under RR scheduling scheme Equation (7), given $\tau_M > 0$ and $\alpha > 0$, assume that there exist matrices $O > 0, S > 0, T > 0, L_i > 0, i = 1, \ldots, N$ and $Y$ with appropriate dimensions such that Equation (15) and Equation (16) are feasible with $J_i = \frac{L_i}{N-1}$, where $G_i$ is given by Equation (30). Then, system Equation (12) is exponentially stable with a prescribed $H_{\infty}$ performance $\gamma$.

**Proof:** The detailed derivation process can refer to [29] and the proof of Theorem 1, which is omitted here due to the limited pages.
3.3. Controller Design under the TOD scheduling scheme Equation (6)

**Theorem 3** Under TOD scheduling scheme Equation (6), for given matrices $A, B, C, F$, and scalars $\tau_M, \alpha > 0, \gamma > 0, \zeta > 0$, system Equation (12) is exponentially stable with a prescribed $H_\infty$ performance $\gamma$, if there exist real matrices $Z > 0, \hat{S} > 0, \hat{T} > 0, i, j = 1, \ldots, N, \hat{J}_i > 0, H_i > 0, \bar{L}_i > 0$ and appropriate dimensions $\hat{Y}, \Xi, \tilde{F}$ such that

$$
\min tr \left\{ \sum_{i=1}^{N} H_i h_i \right\} 
$$

s.t. Equation (17), Equation (32)*, Equation (33), Equation (34), Equation (35)

$$
\begin{bmatrix}
\tilde{\Xi}_{11} & * & * \\
\tilde{\Xi}_{21} & \tilde{\Xi}_{22} & * \\
\tilde{\Xi}_{31} & 0 & \tilde{\Xi}_{33}
\end{bmatrix} < 0,
$$

$$
\begin{bmatrix}
\hat{T} & \hat{Y}^T \\
\hat{Y} & \hat{T}
\end{bmatrix} > 0,
$$

$$
\begin{bmatrix}
h_i & * \\
I & H_i
\end{bmatrix} > 0,
$$

$$
\begin{bmatrix}
-\zeta I & (\Xi C - CZ)^T \\
\Xi C - CZ & -I
\end{bmatrix} < 0,
$$

is solvable, and the controller gain is given by $K = F \Xi^{-1}$, where Equation (32)* is equivalent to Equation (32) by replacing $-H_i^{-1} - Z^T \hat{T}_r^{-1} Z$ with $-h_i, \rho^2 \hat{T}_r - 2pZ$, and

$$
\tilde{\Xi}_{11} = \\
\begin{bmatrix}
\Psi_{11} & \Psi_{12} & \Psi_{13} & \Psi_{14} & \Psi_{15} \\
* & \Psi_{22} & \Psi_{23} & 0 & 0 \\
* & * & \Psi_{33} & 0 & 0 \\
* & * & * & \Psi_{44} & 0 \\
* & * & * & * & \Psi_{55}
\end{bmatrix},
$$

$$
\tilde{\psi}_i = \begin{cases}
\text{diag} \{ \tilde{\psi}_2, \ldots, \tilde{\psi}_N \}, & i_k = 1 \\
\text{diag} \{ \tilde{\psi}_1, \ldots, \tilde{\psi}_{N-1} \}, & i_k = N \\
\text{diag} \{ \tilde{\psi}_1, \ldots, \tilde{\psi}_{j_{ik}}, \ldots, \tilde{\psi}_N \}, & i_k \neq 1, N
\end{cases}
$$

$$
\tilde{\xi}_i = \begin{cases}
[ -BK_2 C_2 Z, \ldots, -BK_N C_N Z ], & i_k = 1 \\
[ -BK_1 C_1 Z, \ldots, -BK_{N-1} C_{N-1} Z ], & i_k = N \\
[ -BK_1 C_1 Z, \ldots, -BK_J C_{j_{ik}}, \ldots, -BK_N C_N Z ], & i_k \neq 1, N
\end{cases}
$$

Proof: Let $Z = O^{-1}, \hat{J}_i = Z J_i Z, \bar{L}_i = Z L_i Z, i = 1, \ldots, N$. Pre- and post-multiplying Equation (15) and Equation (16) with

$$
\text{diag} \{ Z, \ldots, Z, I, T^{-1}, H_i^{-1}, \ldots, H_N^{-1}, I, Z \} \]
Table 1. Configuration of three-area power systems

| Parameter | \( T_1(s) \) | \( T_2(s) \) | \( R \) | \( D \) | \( \beta \) | \( M(s) \) |
|-----------|-------------|-------------|-----|-----|-----|-----|
| Area1     | 0.30        | 0.37        | 0.05| 1.0 | \( \frac{M_1}{M_2} + D_1 \) | 10 |
| Area2     | 0.17        | 0.40        | 0.05| 1.5 | \( \frac{M_1}{M_2} + D_2 \) | 10 |
| Area3     | 0.20        | 0.35        | 0.05| 1.8 | \( \frac{M_1}{M_2} + D_3 \) | 12 |

\( T_{ij} = 0.20, T_{13} = 0.12, T_{23} = 0.25 \) (pu/ rad)

Figure 2. State responses of case 1.

and their transposes, respectively. For the nonlinear terms \(-Z\dot{T}_r^{-1}Z\), \(r = 1, 2\) and \(-H^{-1}_r\), using inequalities \(-Z\dot{T}_r^{-1}Z \leq \rho^2 \dot{T}_r - 2\rho Z\) and the cone complementary linearization algorithm in [27], one can obtain Equation (32). By solving the minimization problem Equation (31), system Equation (12) is exponentially stable with a prescribed \( H_\infty \) performance \( \gamma \) and \( K = F \Xi^{-1} \).

3.4. Controller design under the RR scheduling scheme Equation (7)

Similar to Theorem 5.2 in [29], we establish Theorem 4.

Theorem 4 Under the RR scheduling scheme Equation (7), for given matrices \( A, B, C, F \), and scalars \( \tau_M, \alpha > 0, \gamma > 0, \zeta > 0 \), system Equation (12) is exponentially stable with a prescribed \( H_\infty \) performance \( \gamma \), if there exist real matrices \( Z > 0, \dot{S} > 0, \dot{T} > 0, \dot{L}_i > 0, i = 1, \cdots, N \) and \( \dot{Y}, \Xi, F \) with appropriate dimensions such that Equation (31) is solvable with \( J_i = \frac{1}{N-1}, \) where \( H_i \) is given by Equation (30). The controller gain is given by \( K = F \Xi^{-1} \).

Proof: The detailed derivation process can refer to [29] and the proof of Theorem 3, which is omitted here.

4. AN ILLUSTRATIVE EXAMPLE

In the following, we use a three-area power system [23, 24, 28] interconnected by the shared communication network to demonstrate the effectiveness of main results. Parameters are listed in Table 1.

Case 1: Stability of the studied system under TOD scheduling scheme Equation (6) and \( \omega(t) = 0 \).
Assume parameters are chosen as $\tau_M = 0.1s, \gamma = 10, \rho = 0.63$. We apply Theorem 3 which yields $K_1 = [0.2393, 0.0224], K_2 = [0.2379, -0.1352], K_3 = [0.2324, 0.1965]$. 

Correspondingly, state responses and the switching behavior of active nodes are illustrated by Figure 2 and 3, respectively. Clearly, the designed dynamics output feedback controllers can stabilize the three-area power system under the TOD scheduling scheme Equation (6) in the absence of disturbance.

Case 2: Stability of the studied system under RR scheduling scheme Equation (7) and $\omega(t) = 0$.

To compare with the TOD protocol Equation (6), we use the same parameters as case 1. We apply Theorem 4 which yields $K_1 = [0.1876, 0.0184], K_2 = [0.1899, -0.1596], K_3 = [0.1824, 0.1498]$. Then, state responses and the switching behavior of active nodes are depicted in Figure 4 and 5. From Figure 2-5, one can obtain that the system can be stable under both scheduling protocols Equation (6), Equation (7). Compared with RR protocol, TOD protocol can achieve dynamic scheduling, which makes the control process more efficient.

Case 3: Stability of the studied system under TOD scheduling scheme Equation (6) and $\omega(t) \neq 0$.

According to Theorem 1-4, TOD protocol can degrade into RR protocol under certain conditions. In this case, we take the TOD protocol Equation (6) as an example to verify the anti-disturbance performance of the studied system. Under the disturbance $\omega(t)$ shown in Figure 6, we obtain controller gains $K_1 = [0.4005, -0.1702], K_2 = [0.4839, -0.2094], K_3 = [0.4914, -0.4009]$. State responses of the system are depicted in Figure 7. The designed decentralized controllers under the TOD protocol Equation (6) can ensure system stability with load disturbances.
5. CONCLUSIONS

This paper has designed $H_{\infty}$ output feedback decentralized load frequency controllers for multi-area power systems under the shared but band-limited network. TOD and RR protocols have been used to improve communication efficiency. Since transmission priority has been well designed under scheduling protocols, a higher control performance has been obtained. Then, decentralized output feedback controllers with the prescribed
performance have been designed in different areas. Finally, an example has verified the effectiveness of main results.
