**Background:** Gemcitabine-based chemotherapy is the standard treatment for pancreatic cancer. However, the issue of resistance remains unresolved. The aim of this study was to identify microRNAs (miRNAs) that govern the resistance to gemcitabine in pancreatic cancer.

**Methods:** miRNA microarray analysis using gemcitabine-resistant clones of MiaPaCa2 (MiaPaCa2-RGs), PSN1 (PSN1-RGs), and their parental cells (MiaPaCa2-P, PSN1-P) was conducted. Changes in the anti-cancer effects of gemcitabine were studied after gain/loss-of-function analysis of the candidate miRNA. Further assessment of the putative target gene was performed in vitro and in 66 pancreatic cancer clinical samples.

**Results:** miR-320c expression was significantly higher in MiaPaCa2-RGs and PSN1-RGs than in their parental cells. miR-320c induced resistance to gemcitabine in MiaPaCa2. Further experiments showed that miR-320c-related resistance to gemcitabine was mediated through SMARCC1, a core subunit of the switch/sucrose nonfermentable (SWI/SNF) chromatin remodeling complex. In addition, clinical examination revealed that only SMARCC1-positive patients benefited from gemcitabine therapy with regard to survival after recurrence (P = 0.0463).

**Conclusion:** The results indicate that miR-320c regulates the resistance of pancreatic cancer cells to gemcitabine through SMARCC1, suggesting that miR-320c/SMARCC1 could be suitable for prediction of the clinical response and potential therapeutic target in pancreatic cancer patients on gemcitabine-based therapy.

Pancreatic cancer is one of the leading causes of tumour-related mortalities. The prognosis of patients after complete resection is poor, and > 50% of patients develop tumour recurrence at distant or locoregional sites, with an estimated 5-year survival of only 20% (Li et al., 2004). Treatment modalities for pancreatic cancer include surgery, chemotherapy, radiation therapy, and combination therapy. Gemcitabine-based chemotherapy has formed the core of the multimodal therapy and improved the prognosis of patients with pancreatic cancer (Oettle et al., 2007), but its effect is modest because of high drug resistance. The selection of patients who derive a true benefit from gemcitabine could be an important stepping stone toward improvement of outcome of pancreatic cancer.

Several molecular mechanisms in drug resistance in pancreatic cancer have been elucidated. We have previously described that RRM1, the gene that encodes the regulatory subunit of ribonucleotide reductase, is strongly associated with gemcitabine resistance in pancreatic cancer (Nakahira et al., 2007; Akita et al., 2009). However, the development of drug resistance appears to be a multifactorial process, so our understanding is still fragmentary. Recently, several studies have indicated that microRNAs (miRNAs) regulate this drug resistance (Tomimaru et al., 2010; Tomokuni et al., 2011). miRNAs are endogenous, single-stranded, non-coding RNAs and modulators of gene expression in the post-transcriptional phase, composed of 18–25 nucleotides. Currently, 1600 human miRNAs have been identified (miRBase 19, http://www.mirbase.org/). miRNAs are predicted to control the activity of approximately 30% of all protein-coding genes in mammals, and each miRNA can regulate up to 100 different messenger RNAs. Currently, the most promising miRNAs in association with
pancreatic cancer drug resistance against gemcitabine are miR-15a (Zhang et al., 2010), miR-21 (Park et al., 2009; Ali et al., 2010; Giovannetti et al., 2010; Hwang et al., 2010), miR-34 (Li et al., 2009), miR-200b and miR-200c (Li et al., 2009; Ali et al., 2010), miR-214 (Zhang et al., 2010), miR-221 (Park et al., 2009), and members of the let7 family (Li et al., 2009). However, only selected miRNAs have been investigated for their role in drug resistance in pancreatic cancer.

In this study, we developed gemcitabine-resistant cell clones from human pancreatic cancer cell lines and performed comprehensive expression profiling of miRNAs. The results indicate that miR-320c confers resistance to gemcitabine in pancreatic cancer cells through SMARCC1.

**Real-time quantitative reverse-transcription-PCR for miRNA expression.** The reverse transcription (RT) reaction was performed with the TaqMan MicroRNA RT Kit (Applied Biosystems, Foster City, CA, USA), and real-time quantitative (q) PCR was performed with TaqMan MicroRNA Assays (Applied Biosystems) using the ABI7900HT system (Applied Biosystems). The expression of the target miRNA was normalised relative to that of the endogenous control, RNU48. Data were analysed according to the comparative Ct method (Schmittgen et al., 2004).

**Real-time qRT-PCR for messenger RNA expression.** Complementary DNA was synthesised from 8.0 μg total RNA using the SuperScript first-strand synthesis system (Invitrogen), according to the instructions supplied by the manufacturer. Real-time quantitative PCR was performed using designed oligonucleotide primers and the LightCycler 480 Real-Time PCR system (Roche Diagnostics, Mannheim, Germany). For detection of the amplification products, the LightCycler-DNA master SYBR green 1 (Roche Diagnostics) was used as described previously (Yamamoto et al., 2004), and the amount of target gene expression was calculated. The expression of the target gene was normalised relative to the expression of GAPDH, which was used as an endogenous control. The designed PCR primers were as follows: GAPDH forward primer 5'-GTCCGAGTCAACGGATTTGGT-3' and GAPDH reverse primer 5'-GCCATGGGTGAATCATATTG-3' and SMARCC1 forward primer 5'-TCATGCGGATGCTCCTACCA-3' and SMARCC1 reverse primer 5'-AAACCTCCGCCATCCTGTT-3'.

**MiRNA microarray experiments.** The purified RNAs obtained from MiaPaCa2-P, MiaPaCa2-RGs (MiaPaCa2-RG1, MiaPaCa2-RG2, MiaPaCa2-RG3, and MiaPaCa2-RG4), PSN1-P, and PSN1-RGs (PSN1-RG1, PSN1-RG2, and PSN1-RG3) were used as samples and assessed as being of high quality by the Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA) and NanoDrop (NanoDrop Technologies). Next, 500 ng of extracted total RNA was labeled with Hy5 using the miRCURY LNA Array microRNA Power Labeling kit (Exiqon, Vedbaek, Denmark). The labeled RNAs were hybridised onto 3D-Gene Human miRNA Oligo chips containing 1011 anti-sense probes printed in duplicate spots (Toray, Kamakura, Japan). The annotation and oligonucleotide sequences of the probes conformed to the miRBase miRNA database (http://microrna.sanger.ac.uk/sequences/). After stringent washes, the fluorescent signals were scanned with the ScanArray Express Scanner (Perkin Elmer, Waltham, MA, USA) and analysed using GenePix Pro version 5.0 (Molecular Devices, Sunnyvale, CA, USA). The raw data for each spot were normalised by substitution with the mean intensity of the background signal determined by the signal intensities of all blank spots with 95% confidence intervals. Measurements of both duplicate spots with signal intensities >2 s.d.s. of the background signal intensity were considered to be valid. The relative expression level of a given miRNA was calculated by comparing the signal intensities of the averaged valid spots with their mean value throughout the microarray experiments after normalisation by their median values adjusted equivalently.

**Construction of reporter plasmids and evaluation of luciferase reporter activity.** To construct a luciferase reporter plasmid, a SMARCC1-3'UTR fragment containing the miR-320c target site was subcloned into the pmirGLO Dual-Luciferase miRNA Target Expression Vector (Promega, Madison, WI, USA) located 3' to the firefly luciferase gene. Nucleotide sequences of the constructed plasmids were confirmed by DNA sequencing analysis. For luciferase reporter assays, MiaPaCa2-P were seeded in 96-well plates and then cotransfected with the pmirGLO-SMARCC1-3'UTR construct and either pre-miR-320c or scrambled oligonucleotide for negative control (Ambion) using Lipofectamine 2000.
(Invitrogen). Assays were conducted 48 h after transfection using Dual-Glo Luciferase Assay System (Promega). Firefly luciferase signals were normalised to renilla luciferase signals. All transfection experiments were conducted in triplicate.

**Western blot analysis.** Western blot analysis was performed as described previously (Yamamoto et al., 2003). Briefly, total protein was extracted from cells grown to semi-confluence in radio-immunoprecipitation assay buffer (Thermo Fisher Scientific, Inc., Rockford, IL, USA). Aliquots of total protein (12 μg) were electrophoresed on sodium dodecyl sulfate polyacrylamide, 10% Tris-HCl gels (Bio-Rad Laboratories Inc., Hercules, CA, USA). The separated proteins were transferred to polyvinylidene difluoride membranes (Millipore Co., Billerica, MA, USA) and incubated with primary antibodies for 1 h.

**Growth inhibitory assay.** The growth inhibitory assay was assessed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT; Sigma-Aldrich Co.) assay as described previously (Eguchi et al., 2000). In brief, cells were incubated for 72 h under several concentrations of gemcitabine. After reincubation for 4 h with MTT solution, an acid–isopropanol mixture was added to dissolve the resulting formazan crystals. The absorbance of the plate was measured in a microplate reader at a wavelength of 550 nm with a 650-nm reference, and the results were expressed as a percentage of absorbance relative to that of untreated controls.

**Patients and specimens.** The study subjects were 66 patients with pancreatic cancer, recruited as described previously (Akita et al., 2009). Between January 1992 and March 2008, 166 patients underwent surgery for pancreatic cancer at Osaka University Hospital, Osaka, Japan. We excluded 100 patients for the following reasons: tumours were not resectable in 26 patients because of liver metastases or peritoneal carcinomatosis; surgery resulted in R1 (residual microscopic cancer) or R2 (residual macroscopic cancer) resections in 21 patients; chemotherapy or chemoradiotherapy was provided preoperatively to 37 patients; lack of neutral-buffered formalin-fixed and paraffin-embedded tumour blocks or/and clinical follow-up information for study purposes in 14 cases; and radiotherapy or immunotherapy was provided postoperatively to 2 patients. Because the natural history of variant pancreatic neoplasms differs from that of the usual pancreatic ductal adenocarcinoma, patients with intraductal papillary mucinous neoplasms, mucinous cystic adenocarcinomas, and medullary adenocarcinomas were excluded from this study. Supplementary Table S1 summarises the characteristics of the 66 patients who were enrolled. They included 31 men and 35 women with a mean age of 65.3 ± 7.6 years (± s.d.). All patients had R0 (no residual cancer) resections by pancreaticoduodenectomy in 53 patients, distal pancreatectomy in 11 patients, and other resections in 2 patients. The histopathological grading showed well, moderately, and poorly differentiated adenocarcinoma in 26, 30, and 10 patients, respectively. The UICC-TNM classification was 2, 1, and 63 patients with pT1, pT2, and pT3; 28, 32, and 6 patients with pN0, pN1, and pM1; and 1, 1, 26, 32, and 6 patients with stage IA, IB, IIA, IIB, and IV, respectively. None of the patients had received neoadjuvant therapy preoperatively. All 66 patients were followed until disease recurrence and/or death. The median follow-up period was 17.0 months (3.5–147.7), the 5-year survival rate was 25.0%, and recurrence of disease was observed in 51 patients. Treatment with gemcitabine was carried out in 26 patients; 3 patients received it as adjuvant chemotherapy, and 23 patients received it after disease recurrence. Radiation therapy was not carried out during all the follow-up period.

**Immunohistochemical staining.** Immunohistochemical staining for SMARCC1 in 66 pancreatic cancer samples was performed using the method described previously (Kondo et al., 1999). Briefly, formalin-fixed, paraffin-embedded 4-μm-thick sections were deparaffinised in xylene, then treated with an antigen-retrieval procedure, and incubated in methanol containing 0.3% hydrogen peroxide to block endogenous peroxidase. After incubation with normal protein block serum, the sections were incubated overnight at 4 °C with an anti-SMARCC1 antibody as the primary antibody. Thereafter, the sections were detected with avidin–biotin complex reagents (Vector Laboratory Inc., Burlingame, CA, USA) and diaminobenzidine. All sections were counterstained with haematoxylin. The positivity for SMARCC1 staining was defined as detectable nuclear staining of >10% of cancer cells.

**Statistical analysis.** Data are expressed as means ± s.d. Clinicopathological parameters were compared using the χ² test, and continuous variables were compared using the Student’s t-test. Survival curves were computed using the Kaplan–Meier method, and differences between survival curves were compared using the log-rank test. A P value < 0.05 denoted the presence of a statistically significant difference. Statistical analysis was performed using JMP software version 8.0.2 (SAS Institute Inc., Cary, NC, USA).

## RESULTS

### Characteristics of established gemcitabine-resistant cells.

The morphology of MiaPaCa2-RGs resembled that of MiaPaCa2-P. Although MiaPaCa2-RGs showed similar growth curves compared with MiaPaCa2-P in the absence of gemcitabine (data not shown), MiaPaCa2-RGs were significantly resistant to gemcitabine compared with MiaPaCa2-P, which MTT assays confirmed (Figure 1A). On the other hand, the morphology of PSN1-RGs was slightly spindle-like in comparison with that of PSN1-P, and the growth rate of PSN1-RGs was slightly slower than that of PSN1-P in the absence of gemcitabine (data not shown). MTT assays showed significant resistance to gemcitabine in PSN1-RGs compared with PSN1-P (Figure 1B).

**miR-320c expression was significantly higher in gemcitabine-resistant clones than in parental cells.** To identify the candidate miRNAs related to resistance to gemcitabine, miRNA microarray analysis was performed using a MiaPaCa2 combination (MiaPaCa2-P and MiaPaCa2-RGs) and PSN1 combination (PSN1-P and PSN1-RGs). The analysis showed that, among the 1011 miRNAs, the miRNA expression levels of 20 (2.0%) in MiaPaCa2-RGs (Supplementary Table S2) and 74 (7.3%) in PSN1-RGs (Supplementary Table S3), respectively, were altered by > 1.5 average fold relative to parental, keeping adequate expression quantities and excluding miRNA’s. Furthermore, eight miRNAs were identified in common both in MiaPaCa2-RGs and PSN1-RGs (Figure 1C). These miRNAs are listed with average fold change and P values of MiaPaCa2-RGs relative to MiaPaCa2-P and PSN1-RGs relative to PSN1-P in Table 1. Among them, miR-320c showed the highest alteration (1.97 average fold change; 2.20-fold increase in MiaPaCa2-RGs, and 1.73-fold increase in PSN1-RGs) and was statistically significant (P = 0.0033 in MiaPaCa2-RGs, P = 0.0036 in PSN1-RGs). The results of real-time qRT-PCR for miR-320c confirmed the upregulation in MiaPaCa2-RGs (Figure 1D). Therefore, miR-320c was selected for further analysis.

**Gain-of-function and loss-of-function of miR-320c alters the resistance of MiaPaCa2 cells to gemcitabine.** To evaluate the effect of miR-320c on the response to gemcitabine in MiaPaCa2 cells, pre-miR-320c was first transfected into MiaPaCa2-P. Real-time qRT-PCR showed that transfection of pre-miR-320c markedly increased the miR-320c expression level for over 72 h (Figure 2A). The MTT assay demonstrated that transfection of pre-miR-320c into MiaPaCa2-P induced resistance to gemcitabine treatment
To further assess the effect of miR-320c on the gemcitabine resistance, anti-miR-320c was transfected into MiaPaCa2-RG1. Real-time qRT-PCR showed sufficient inhibition of miR-320c expression for over 72 h (Figure 2B), and the MTT assay demonstrated significant reduction of viability of anti-miR-320c-transfected cells compared with the control cells (Figure 2D). These results indicate that, at least partially, miR-320c induces gemcitabine resistance in MiaPaCa2 cells.

Table 1. Common up- or downregulated miRNAs both in MiaPaCa2-RGs and PSN1-RGs

| miR no. | Fold change (relative to MiaPaCa2-P) | Fold change (relative to PSN1-P) |
|---------|-------------------------------------|----------------------------------|
|         | MiaPaCa2-RGs (average) | PSN1-RGs (average) | P-value | PSN1-RGs (average) | P-value | Ref sequence ID |
| Common upregulated miRNAs both in MiaPaCa2-RGs and PSN1-RGs |
| hsa-miR-320c | 1.97 | 2.20 | 0.0033 | 1.73 | 0.0366 | MIMAT0005793 |
| hsa-miR-29a | 1.85 | 2.13 | 0.0097 | 1.57 | 0.2751 | MIMAT0000086 |
| hsa-miR-10a | 1.69 | 1.64 | 0.0202 | 1.73 | 0.0606 | MIMAT0000253 |
| hsa-miR-30c | 1.68 | 1.54 | 0.0222 | 1.81 | 0.0384 | MIMAT000244 |
| hsa-miR-30a | 1.65 | 1.51 | 0.0243 | 1.79 | 0.2634 | MIMAT000087 |
| hsa-miR-29b | 1.58 | 1.53 | 0.0026 | 1.63 | 0.3311 | MIMAT000100 |
| hsa-miR-320a | 1.56 | 1.51 | 0.0142 | 1.61 | 0.0556 | MIMAT0000510 |
| Common downregulated miRNAs both in MiaPaCa2-RGs and PSN1-RGs |
| hsa-miR-1246 | 3.65 | 1.97 | 0.0085 | 5.32 | 0.1209 | MIMAT0005898 |

Abbreviations: MiaPaCa-P = parental MiaPaCa2 cells; MiaPaCa2-RGs = gemcitabine-resistant clones of MiaPaCa2; miR and miRNA = microRNA; PSN1-P = parental PSN1 cells; PSN1-RGs = gemcitabine-resistant clones of PSN1.
miR-320c inhibits the response to gemcitabine by targeting SMARCC1. Few studies have reported miR-320 expression in gastrointestinal cancers, and little is known about the function of this miRNA. As putative targets of miR-320c, 539 genes were predicted by TargetScan. Among them, SMARCC1, a component of the chromatin remodeling complex, also known as a tumour suppressor, was selected for further analysis. SMARCC1 expression was lower in MiaPaCa2-RG1 than in MiaPaCa2-P (Figure 3A). We investigated direct binding of miR-320c and the SMARCC1 gene by luciferase assay in MiaPaCa2-P and observed reduction of the luciferase activity in the pre-miR-320c-treated cells in comparison with negative control (Supplementary Figure S1). Pre-miR-320c transfection decreased SMARCC1 expression, and anti-miR-320c transfection increased it (Figures 3B and C), suggesting that SMARCC1 is one of the target genes of miR-320c in MiaPaCa2 cells. Next, we used siRNA for SMARCC1 to validate its involvement in the resistance to gemcitabine. Knockdown of SMARCC1 was confirmed by western blot analysis (Figure 3D). The MTT assay demonstrated that transfection of siSMARCC1 decreased the resistance of MiaPaCa2-P to gemcitabine (Figure 3E). These results suggest that SMARCC1 mediates, at least in part, the miR-320c-related resistance to gemcitabine.

SMARCC1 expression in clinical pancreatic cancer samples. Pancreatic cancer samples of 66 patients who underwent R0 resection were immunohistochemically stained for SMARCC1 expression. Whereas the expression of SMARCC1 in pancreatic cancer lesions varied among the patients, a homogeneous staining for SMARCC1 was observed in the nucleus in normal pancreatic duct cells (Figure 4A). Although SMARCC1 has shown to appear not only in the nucleus but also in the cytoplasm in the previous study (Andersen et al, 2009), functional SMARCC1 protein is considered to localise in the nucleus, therefore we defined SMARCC1-positive samples as having the spotted granular nuclear pattern (Figure 4B) and SMARCC1-negative samples as having the cytoplasmic pattern (not stained in the nucleus) (Figure 4C) or the negative pattern (not stained in the nucleus or the cytoplasm) (Figure 4D) in pancreatic cancer lesions. Among the 66 patients examined, 31 (47.0%) showed positive staining whereas 35 (53.0%) patients were negative for SMARCC1.

SMARCC1 expression was not associated with overall and disease-free survival. Of all the 66 patients, the median overall survival was 17.0 months (3.5–147.7), and the median disease-free survival was 11.1 months (2.0–147.7). There were no significant differences between the groups who were SMARCC1 positive and negative with respect to age, sex, histopathological type (well/mod/poor), tumour size, tumour location (head/body/tail), pathological depth of tumour (pT1/T2/T3), and whether or not gemcitabine was used as chemotherapy. However, pathological lymph node metastasis and pathological stage were significantly different in the two groups (P = 0.0383, Supplementary Table S4). The Kaplan–Meier overall survival estimates were not significantly different for patients who were SMARCC1 positive compared with those with SMARCC1-negative expression (median overall survival: 1.693 vs 2.189 years, P = 0.5585; Supplementary Figure S2A). With regard to disease-free survival, there was no significant difference between the SMARCC1-positive and -negative groups (median disease-free survival, 0.956 vs 1.334 years, P = 0.5633; Supplementary Figure S2B).

SMARCC1 was a useful predictor of clinical response to gemcitabine therapy. Of the 66 patients, 26 received therapy with single-agent gemcitabine. In 23 patients, this treatment was
initiated at the time of tumour recurrence. To elucidate the relationship between SMARCC1 expression and gemcitabine therapy, we used survival after recurrence, which represented the period from starting gemcitabine therapy or other therapies in 51 patients with relapse, until death. There were no significant differences between patients with and without gemcitabine therapy in clinicopathological factors (Table 2). First, we examined the survival benefit of gemcitabine. The 23 patients who were treated with gemcitabine had a significantly better survival than those who did not ($P = 0.0046$; Supplementary Figure S3). After dividing patients who were treated with gemcitabine into SMARCC1-positive and -negative groups, only patients who were SMARCC1 positive benefited from gemcitabine therapy ($P = 0.0463$). The relationship between SMARCC1 and survival after recurrence was not significant in patients treated without gemcitabine therapy ($P = 0.9095$; Figure 5).
DISCUSSION

Several studies have examined the involvement of miR-320c in various types of cancer. It has been reported that miR-320c is upregulated in breast cancer (Yan et al, 2008), retinoblastoma (Zhao et al, 2009), and malignant transformed bronchial epithelial cells (Shen et al, 2009; Duan et al, 2010), whereas it is downregulated in lung cancer (Gao et al, 2011) and in cholangiocarcinoma (Chen et al, 2009). It has also been reported that miR-320 is regulated by PTEN in mammary stromal fibroblasts (Bronisz et al, 2012), correlates with recurrence-free survival in colon cancer (Schepler et al, 2008), and inhibits proliferation in leukaemia (Schaar et al, 2009). Regarding the association of miR-320 and drug resistance, it has recently been reported that miR-320 facilitates chemotherapeutic drug-triggered apoptosis in cholangiocarcinoma (Chen et al, 2009). The present study identified miR-320c as one of the common upregulated
miRNAs in gemcitabine-resistant pancreatic cancer cells compared with their parental cells, and we showed that miR-320c induced the resistance to gemcitabine. Among the putative targets of miR-320c by TargetScan, we focussed on SMARCC1, a switch/sucrose nonfermentable (SWI/SNF)-related matrix-associated actin-dependent regulator of chromatin subfamily C member 1, also known as BAF155 (BRG1-associated factor 155), as a candidate molecule responsible for miR-320-mediated drug resistance because of recent studies suggesting a role of chromatin remodeling in some cancers. Drug resistance is the major cause of treatment failure in cancer, yet the multifactorial mechanisms responsible for resistance remain largely unknown. Recently, several studies reported the contribution of chromatin remodeling in drug resistance in various types of cancer, such as the DEK oncogene in melanoma (Khodadoust et al., 2009), remodeling and spacing factor 1 in ovarian cancer (Choi et al., 2009), enhancer of zeste homolog 2 in pancreatic cancer (Aghdasi et al., 2008), and chromatin remodeling at the topoisoerase II-beta promoter in neuroblastoma (Das et al., 2010). Unlike DNA mutations, which are essentially irreversible in cancer, chromatin alterations, including both histone modifications and nucleosome remodeling, are potentially reversible and thus might constitute attractive therapeutic targets (Wilson and Roberts, 2011). The SWI/SNF chromatin remodeling complex is a 2-Mda multisubunit complex first identified in yeast and highly conserved among eukaryotes (Peterson, 1996). Transcriptional activation and efficient transcription of genes require dynamic structural changes in chromatin, and the ATP-dependent SWI/SNF complex is involved in chromatin restructuring (Percipalle and Farrants, 2006).

The SWI/SNF chromatin remodeling complex consists of a catalytic ATPase subunit, core subunits, and variant subunits. SMARCC1 is contained in the core subunits. The SWI/SNF complexes have a widespread role in tumour suppression (Wilson and Roberts, 2011). Inactivating deletion and mutations in SWI/SNF subunits have been reported at high frequency in various cancers, such as SNF5 in rhabdoid tumours (Versteege et al., 1998), ARID1A in renal cell carcinoma (Varela et al., 2011), ARID1A (Jones et al., 2010; Wiegand et al., 2010) and BAF155 (DelBove et al., 2011) in ovarian carcinoma, and BRG1, BRM, ARID1A, ARID1B, and BAF180 in pancreatic cancer (Shain et al., 2012). In addition, some SWI/SNF subunit deficiencies correlate with malignant potential, including drug resistance and shorter survival in melanoma (Lin et al., 2009) and in ovarian carcinoma (Katagiri et al., 2012) and glucocorticoid resistance in acute lymphoblastic leukaemia (Pottier et al., 2008), and as a severe risk factor for histologically malignant gastric cancer (Yamamichi et al., 2007). Some studies have reported that SMARCC1 deficiency prevents DNA damage–induced cell death (Ahn et al., 2011) and predicts short-term survival of colorectal cancer (Andersen et al., 2009). In addition, knockdown of SMARCC1 promotes self-renewal gene expression in embryonic stem cells (Schanien et al., 2009). In the present study, we used MiaPaCa2-P and MiaPaCa2-RG1 and showed that knockdown of SMARCC1 induced gemcitabine resistance, and both gain-of-function and loss-of-function of miR-320c inversely altered the expression level of SMARCC1 protein. Although SMARCC1 may be only one of the responsible molecules, the molecule is shown to be involved, at least partly, in the miR-320c-related drug-resistance.

Evaluating the expression of miR-320c in clinical specimens may be crucial in predicting the drug-resistance, yet SMARCC1 may be practically easier and more useful than miR-320c. Thus, in the present study, we evaluated the clinical importance of SMARCC1 rather than miR-320c. We have previously reported RRM1 expression as the beneficial predictor of the clinical response to gemcitabine in pancreatic cancer patients after a complete resection (Akita et al., 2009). The present study revealed a significant association between SMARCC1 expression and the clinical response to gemcitabine in completely resected pancreatic cancer patients. Therefore, RRM1, the key enzyme involved in DNA synthesis, and SMARCC1, the core subunit of the SWI/SNF chromatin remodeling complex, appear to make a contribution to drug-resistance mechanisms in separate processes and not to depend on each other. SMARCC1 expression could be a newly independent predictor of the clinical response to gemcitabine in pancreatic cancer patients.

Table 2. Relationship between gemcitabine therapy and clinicopathological factors

| Gemcitabine therapy | Treated (n = 23) | Not treated (n = 28) | P-value |
|---------------------|----------------|---------------------|---------|
| Age (<65 : ≥ 65 years) | 13:10 | 12:16 | 0.3314 |
| Sex (male:female) | 11:12 | 11:14 | 0.8772 |
| Histopathological type (well or mod.poor) | 21:2 | 22:6 | 0.2134 |
| Tumour size (<27 : ≥ 27 mm) | 12:11 | 12:16 | 0.5071 |
| Tumour location (head body or tail) | 18:5 | 22:6 | 0.9786 |
| Pathological depth of invasion pT (T1 or T2:T3) | 2.21 | 1.27 | 0.4390 |
| Pathological lymph node metastasis pN (negative:positive) | 5:18 | 11:17 | 0.1790 |
| Pathological stage (Ia or Ib or IIa:IIb or III) | 5:18 | 11:17 | 0.1790 |
| SMARCC1 expression (+/-) | 11:12 | 15:13 | 0.6830 |

Abbreviations: mod = moderately differentiated; poor = poorly differentiated; well = well differentiated.
In conclusion, we demonstrated in the present study that miR-320c inhibited the anti-cancer effect of gemcitabine in pancreatic cells and that SMARCC1 mediated this effect. The response to gemcitabine in MiaPaCa2 cells was controlled by genetic manipulation of miR-320c and SMARCC1. In addition, clinical examination revealed that only patients who were SMARCC1 positive benefited from gemcitabine therapy with regard to survival after recurrence. Considered together, the results suggest that miR-320c/SMARCC1-mediated gemcitabine resistance is a potential legitimate target for the treatment of pancreatic cancer.

**ACKNOWLEDGEMENTS**

We thank Nariaki Matsuura (Department of Molecular Pathology, Graduate School of Medicine, Osaka University, Osaka, Japan) for advice on immunohistochemical analysis.

**CONFLICT OF INTEREST**

The authors declare no conflict of interest.
