Abstract

We demonstrate that the spatial resolution of images in optical tomography is not limited to the fundamental length scale of one transport mean free path. This result is facilitated by the introduction of novel corrections to the standard integral equations of scattering theory within the diffusion approximation to the radiative transport equation.
There has been considerable recent interest in the development of optical methods for tomographic imaging \[1\]. The physical problem that is considered is to recover the optical properties of the interior of an inhomogeneous medium from measurements taken on its surface. The starting point for the mathematical formulation of this inverse scattering problem (ISP) is a model for the propagation of light, typically taken to be the diffusion approximation (DA) to the radiative transport equation (RTE). The DA is valid when the energy density of the optical field varies slowly on the scale of the transport mean free path $\ell^*$. The DA breaks down in optically thin layers, near boundary surfaces, or near the source. One or more of these conditions are encountered in biomedical applications such as imaging of small animals \[2\] or of functional activity in the brain.

Within the accuracy of the DA, reconstruction algorithms based on both numerical \[3\] and analytic solutions \[4, 5, 6\] to the ISP have been described. Regardless of the method of inversion, the spatial resolution of reconstructed images is expected to be limited to $\ell^*$. This expectation is due to the intertwined effects of the ill-posedness of the ISP \[5\] and intrinsic inaccuracies of the DA \[7\]. In this Letter, we introduce novel corrections to the integral equations of scattering theory within the DA. Using this result, we report the reconstruction of superresolved images whose spatial resolution is less than $\ell^*$.

We begin by considering the propagation of multiply-scattered light in an inhomogeneous medium characterized by an absorption coefficient $\mu_a(r)$. In what follows, we will neglect the contribution of ballistic photons and consider only diffuse photons whose specific intensity $I(r, \hat{s})$ at the point $r$ in the direction $\hat{s}$ is taken to obey the time-independent RTE

$$\hat{s} \cdot \nabla I(r, \hat{s}) + (\mu_a + \mu_s)I(r, \hat{s}) - \mu_s \int d^2 s' A(\hat{s}, \hat{s}')I(r, \hat{s}') = S(r, \hat{s}),$$

(1)

where $\mu_s$ is the scattering coefficient, $A(\hat{s}, \hat{s}')$ is the scattering kernel, and $S(r, \hat{s})$ is the source. The change in specific intensity due to spatial fluctuations in $\mu_a(r)$ can be obtained from the integral equation

$$\phi(r_1, \hat{s}_1; r_2, \hat{s}_2) = \int d^3 r d^2 s G(r_1, \hat{s}_1; r, \hat{s})G(r, \hat{s}; r_2, \hat{s}_2)\delta \mu_a(r).$$

(2)

Here the data function $\phi(r_1, \hat{s}_1; r_2, \hat{s}_2)$ is proportional, to lowest order in $\delta \mu_a$, to the change in specific intensity relative to a reference medium with absorption $\mu^0_a$, $G$ is the Green’s function for \[1\] with $\mu_a = \mu^0_a$, $\delta \mu_a(r) = \mu_a(r) - \mu^0_a$, $r_1, \hat{s}_1$ and $r_2, \hat{s}_2$ denote the position and direction of a unidirectional point source and detector, respectively.
We now show that the integral equation \((2)\) may be used to obtain corrections to the usual formulation of scattering theory within the DA. To proceed, we note that, following Ref. \([6]\), the Green’s function \(G(\mathbf{r}, \mathbf{s}; \mathbf{r}', \mathbf{s}')\) may be expanded in angular harmonics of \(\hat{s}\) and \(\hat{s}'\):

\[
G(\mathbf{r}, \mathbf{s}; \mathbf{r}', \mathbf{s}') = \frac{c}{4\pi} \left(1 + \ell^* \hat{s} \cdot \nabla_r \right) \left(1 - \ell^* \hat{s}' \cdot \nabla_{r'} \right) G(\mathbf{r}, \mathbf{r}') ,
\]

where \(\ell^* = 1/[\mu_a^0 + \mu'_s]\) with \(\mu'_s = (1 - g)\mu_s, g\) being the anisotropy of the scattering kernel \(A\). The Green’s function \(G(\mathbf{r}, \mathbf{r}')\) satisfies the diffusion equation \((-D_0 \nabla^2 + \alpha_0) G(\mathbf{r}, \mathbf{r}') = \delta(\mathbf{r} - \mathbf{r}')\), where the diffusion coefficient \(D_0 = 1/3c\ell^*\) and \(\alpha_0 = c\mu_0^D\). In addition, the Green’s function must satisfy boundary conditions on the surface of the medium (or at infinity in the case of free boundaries). In general we will consider boundary conditions of the form \(G(\mathbf{r}, \mathbf{r}') + \ell \hat{n} \cdot \nabla G(\mathbf{r}, \mathbf{r}') = 0\), where \(\hat{n}\) is the outward unit normal to the surface bounding the medium and \(\ell\) is the extrapolation distance. Making use of \((3)\) and performing the angular integration over \(\hat{s}\) in \((2)\) we obtain

\[
\phi(\mathbf{r}_1, \hat{s}_1; \mathbf{r}_2, \hat{s}_2) = \frac{c}{4\pi} \Delta_1 \Delta_2 \int d^3r \left[G(\mathbf{r}_1, \mathbf{r})G(\mathbf{r}_2, \mathbf{r}) - \frac{\ell^*^2}{3} \nabla_r G(\mathbf{r}_1, \mathbf{r}) \cdot \nabla_r G(\mathbf{r}, \mathbf{r}_2)\right] \delta\alpha(\mathbf{r}) ,
\]

where the differential operators \(\Delta_k = 1 - (-1)^k \ell^* \hat{s}_k \cdot \nabla_{r_k}\) with \(k = 1, 2\) and \(\delta\alpha = c\delta\mu_a\). Note that if the source and detector are oriented in the inward and outward normal directions, respectively, then \((4)\) becomes

\[
\phi(\mathbf{r}_1, -\hat{n}(\mathbf{r}_1); \mathbf{r}_2, \hat{n}(\mathbf{r}_2)) = \frac{c}{4\pi} \left(1 + \frac{\ell^*}{\ell}\right)^2 \int d^3r \left[G(\mathbf{r}_1, \mathbf{r})G(\mathbf{r}, \mathbf{r}_2) - \frac{\ell^*^2}{3} \nabla_r G(\mathbf{r}_1, \mathbf{r}) \cdot \nabla_r G(\mathbf{r}, \mathbf{r}_2)\right] \delta\alpha(\mathbf{r}) ,
\]

where we have used the boundary conditions on \(G\) to evaluate the action of the \(\Delta_k\) operators. Eq. \((5)\) is the main theoretical result of this Letter. It may be viewed as providing corrections to the DA since the first term on the right hand side of \((5)\) corresponds to the standard DA in an inhomogeneous absorbing medium. We note that the second term may be interpreted as defining an effective diffusion coefficient \(D(\mathbf{r}) = D_0 - (\ell^*^2/3)\delta\alpha(\mathbf{r})\) since the expression \(\nabla_r G(\mathbf{r}_1, \mathbf{r}) \cdot \nabla_r G(\mathbf{r}, \mathbf{r}_2)\) defines the diffusion kernel in a medium with an inhomogeneous diffusion coefficient \([3]\).

For the remainder of this paper we will work in the planar measurement geometry, often encountered in small-animal imaging. In this case, \((4)\) becomes

\[
\phi(ho_1, rho_2) = \int d^3r K(\rho_1, \rho_2; \mathbf{r}) \delta\alpha(\mathbf{r}) ,
\]

\((6)\)
where \( \rho_1 \) denotes the transverse coordinates of a point source in the plane \( z = 0 \), \( \rho_2 \) denotes the transverse coordinates of a point detector in the plane \( z = L \), and the dependence of \( \phi \) on \( \hat{s}_1 \) and \( \hat{s}_2 \) is not made explicit. Evidently, from considerations of invariance of the kernel \( K(\rho_1, \rho_2; r) \) under translations of its transverse arguments, it can be seen that \( K \) may be expressed as the Fourier integral

\[
K(\rho_1, \rho_2; r) = \frac{1}{(2\pi)^4} \int d^2q_1 d^2q_2 \kappa(q_1, q_2; z) \exp \left[ i(q_1 - q_2) \cdot \rho - i(q_1 \cdot \rho_1 - q_2 \cdot \rho_2) \right],
\]

where \( r = (\rho, z) \). The function \( \kappa \) may be obtained from the plane-wave expansion of the diffusion Green’s function obeying appropriate boundary conditions. In the case of free boundaries, it is readily seen that \( \kappa \) is given by the expression

\[
\kappa(q_1, q_2; z) = \frac{c}{16\pi D_0^2 Q(q_1)Q(q_2)} \left[ 1 + \frac{\ell^2}{3} (Q(q_1)Q(q_2) - q_1 \cdot q_2) \right]
\times \left[ 1 + \ell^* (Q(q_1) + Q(q_2)) + \ell^2 Q(q_1)Q(q_2) \right] \exp \left[ -Q(q_1)|z| - Q(q_2)|z - L| \right],
\]

where \( Q(q) = (q^2 + \alpha_0/D_0)^{1/2} \) and we have assumed that \( \hat{s}_1 = \hat{s}_2 = \hat{z} \).

Inversion of the integral equation (6) may be carried out by analytic methods. These methods have been shown to be computationally efficient and may be applied to data sets consisting of a very large number of measurements [5, 6]. The approach taken is to construct the singular value decomposition of the linear operator \( K \) in the proper Hilbert space setting and then use this result to obtain the pseudoinverse solution to (6). In this manner, it is possible to account for the effects of sampling and thereby obtain the best (in the sense of minimizing the appropriate \( L^2 \) norm) bandlimited approximation to \( \delta \alpha \). Here we use this approach to simulate the reconstruction of a point absorber located at a point \( r_0 \) between the measurement planes with \( \delta \alpha(r) = A\delta(r - r_0) \) for constant \( A \). In this situation it is possible to calculate the data function \( \phi \) within radiative transport theory, thus avoiding “inverse crime.” To proceed, we require the Green’s function \( G(r, \hat{s}; r', \hat{s}') \) for the RTE in a homogeneous infinite medium which we obtain as described in Ref. [8]. Note that in this case, the angular integration over \( \hat{s} \) in (2) may be carried out analytically.

The effects of corrections to the DA were studied in numerical simulations following the methods of Ref. [3]. The simulations were performed for a medium with optical properties similar to breast tissue in the near infrared [9]. The background absorption and reduced scattering coefficients were given by \( \mu_a^0 = 0.03 \text{ cm}^{-1} \) and \( \mu_s' = 10 \text{ cm}^{-1} \). The scattering kernel was taken to be of Henyey-Greenstein type with \( A(\hat{s}, \hat{s}') = \sum_{\ell=0}^\infty g^\ell P_\ell(\hat{s} \cdot \hat{s}') \) and
\( g = 0.98 \). This choice of parameters corresponds to \( \ell^* = 1 \) mm and \( D_0 = 0.8 \) cm\(^2\)ns\(^{-1}\). The separation between the measurement planes \( L \) was varied in order to explore the effects of the corrections. A single point absorber was placed at the midpoint of the measurement planes with \( r_0 = (0, 0, L/2) \) and \( A = 1 \) cm\(^3\) ns\(^{-1}\). The sources and detectors were located on a square lattice with spacing \( h \). The total number of source-detector pairs \( N \) was varied, along with \( h \), as indicated below. To demonstrate the stability of the reconstruction in the presence of noise, Gaussian noise of zero mean was added to the data at the 1% level, relative to the average signal. Note that the level of regularization was chosen to be the same for all reconstructions.

Reconstruction of \( \delta \alpha(r) \) for a point absorber defines the point spread function (PSF) of the reconstruction algorithm. The resolution \( \Delta x \) is defined as the half width at half maximum of the PSF. In Fig. 1(a) we consider the case of a thick layer with \( L = 6.6 \) cm. The above parameters were chosen to be \( h = 0.83 \) mm and \( N = 1.5 \times 10^9 \). PSFs with and without corrections are shown. It may be seen that the effect of the corrections is negligible in the case of a thick layer and the resolution \( \Delta x = 3.5\ell^* \). For the case of a layer of intermediate thickness with \( L = 1.1 \) cm, as shown in Fig. 1(b), the corrections have a more significant effect. In particular, with \( h = 0.28 \) mm and \( N = 1.2 \times 10^{11} \), we found that \( \Delta x = 0.9\ell^* \) for the uncorrected reconstruction and \( \Delta x = 0.7\ell^* \) for the corrected reconstruction. The corrections are most significant for the thinnest layer considered in this study, achieving a factor of two improvement in resolution when \( L = 0.55 \) cm. In this case, with \( h = 0.14 \) mm and \( N = 1.9 \times 10^{12} \), we found that \( \Delta x = 0.4\ell^* \) for the uncorrected case and \( \Delta x = 0.2\ell^* \) for the corrected case as shown in Fig. 1(c). Note that the number of source-detector pairs \( N \approx 10^9 \sim 10^{12} \) may be achieved in modern non-contact optical tomography systems [10].

In conclusion, we have described a series of corrections to the usual formulation of the DA in optical tomography. We have found that these corrections give rise to superresolved images with resolution below \( \ell^* \). Several comments on these results are necessary. First, the effects of corrections were demonstrated to be most significant in optically thin layers. However, corrections to the DA may also be expected to be important for thick layers when inhomogeneities in the absorption are located near the surface. Second, the results of this study were obtained without resorting to so-called inverse crime. That is, forward scattering data was obtained from the full RTE under conditions when the DA is known to break down. Third, the use of analytic reconstruction algorithms was essential for handling the extremely
large data employed in this study. Finally, we note that higher order corrections to the DA are also expected to be important for the nonlinear ISP.
