Abstract: Rijndael-The AES[1-3] is 128-bit block cipher based on an elegant algebraic structure over $F_2^8$. This cipher employs a simple approach to its substitution, permutation (SP) operations. We take a close look at its internals; the byte substitution transformation function is the only non-linear function in Rijndael - The AES. This transformation comprises of two steps operating on each byte. Here we are trying to remodel this to one step operation using indicator vector matrix representation. This representation is further extended to mathematically represent one complete encryption or decryption round of Rijndael the using indicator vector matrix representation that can be explored for better cryptoanalysis[4,5] of the cipher.

Key words: Rijndael, byte substitution transformation, indicator vector matrix

INTRODUCTION

Rijndael Algorithm[1-3] was designed by two Belgian cryptographers: Vincent Rijmen and John Daemen, as one of the candidates for the Advanced Encryption Standard (AES) selection. The AES committee was formulated by the U.S. Government under the umbrella of National Institute of Standards and Technology (NIST) to find another cryptographic algorithm in order to replace the existing 64-bit block cipher of 1977 - the Data Encryption Standards (DES) to protect sensitive digital information over the next few decades.

After a stringent qualifying process of three rounds involving the whole world’s cryptographic community[6], Rijndael algorithm was proposed by the AES committee as Advanced Encryption Standard – The AES on Nov. 26, 2001. Later on May 26, 2002 NIST endorsed it as Federal Information Processing Standard namely FIPS-197 replacing DES (FIPS-46).

Rijndael possesses an elegant algebraic structure over $F_2^8$[7-10]. It supports a variable block size and variable key size of 128, 160, 192, 224 or 256 bits each. But for the AES, its block size is fixed to 128-bits and keeping the variable key size of 128, 192 and 256 bits. It has 10, 12 or 14 iterations of round transformations depending on the key size of 128, 192 or 256 bits respectively in conjunction with an initial round of key addition. Each (except the last) round transformation function is composed of the four sub transformation functions: Byte Substitution or $bs$, Row Shift or $rs$, Mix Column or $mc$ and Add Round Key or $ak$. The last round transformation does not include the $mc$ function.

In this study we present an analysis of the block cipher Rijndael while concentrating on its 128-bit version. This cipher employs a simple approach to its substitution, permutation (SP) operations. We take a close look at its internals, recast some of these and present the cipher in a manner amenable for better analysis.

Notations: We fix the block size and key size to 128 bit. We consider the 10 round version. We use the following notations.

Let for all round index $i = 0,...,10$ and byte index $j = 0,...,15$ :

$x_{i,j}$ - $i$-th text byte of $i$-th round (in particular, $x_{0,j}^0$ is the initial input plain text byte and is fixed $x_{11,j}^1$ - $i$-th cipher text byte.

$k_{i,j}^0$ - $i$-th expanded key byte of $i$-th round (in particular $k_{j}^0$ is the user defined key :

$W[i]$ = $i$-th key word of 32 bits.

$k_{n}$ = $n$-th key byte, $n = \{0,1,2,...,175\}$

$N_k =$ (key size)/32 = 128/32 = 4.

$N_b =$ (block size)/32 = 128/32 = 4.

$N_r =$ No. of cipher rounds = 10.

We use the standard convention of representing elements of $F_2^8$ as polynomials of degree 7, over $F_2$. We also adopt the standard practice of treating the elements of $F_2^8$ as integers in the range 0, ..., 255. Thus for example, $\alpha \in F_2^8$ with $\alpha = x^7 + x^6 + x^2 + x^1 + 1$ would be referred as $\alpha = 199$, without ambiguity.
We define three functions namely \( Rotbyte() \), \( Rc() \), \( Rcon() \) & \( Iv() \) an indicator vector:

i. \( Rotbyte() \) rotates the bytes of key within the word, when word oriented structure is considered for key expansion mechanism. If \( k_0,k_1,k_2,k_3 \) are four bytes of \( i \)-th key-word \( W[i] \) arranged in big endian format, \( Rotbyte(W[k_0,k_1,k_2,k_3]) = W[k_1,k_2,k_3,k_0] \)

The byte substitution transformation of Rijndael uses an S-box, generated over \( F_{2^8} \) with \( (x+1)=(03_{base \ 16}) \) as primitive element and \( g(x)=x^8+x^4+x^3+x+1 \) as the defining irreducible polynomial along with an affine transformation of \( x^6+x^5+x+1=(63_{base \ 16}) \). Thus, \( bs \), using S-box, transforms the individual byte \( a(x) \) to \( bs(a(x)) \).

Mathematically:

\[
bs(a(x)) = x^6 + x^5 + x + 1 + c(x)(x^4 + x^3 + x^2 + x + 1)(mod(x^8 + 1))
\]

where \( c(x) = a(x)^{-1}(mod\ g(x)) \)

Similarly

\[
bs(W[k_0,k_1,k_2,k_3]) = W[bs(k_0),bs(k_1),bs(k_2),bs(k_3)]
\]

and

\[
Rotbyte( W[k_0,k_1,k_2,k_3] ) = W[bs(k_1),bs(k_2),bs(k_3),bs(k_0)]
\]

ii. \( Rc(a(x)) \) is another round dependent byte oriented constant function defined over \( F_{2^8} \). \( POW(a(x)) \) contains powers of \( a(x) \) in the field. Then

\[
Rc(a(x)) = POW(a(x))(mod\ g(x))
\]

In particular, for \( a(x) \in \{1,2,\ldots,10\} \)

\[
Rc(a(x)) = \{1,2,4,8,16,32,64,128,257,256\}
\]

iii. \( Rcon(a(x)) \) is a round dependent word oriented function such that \( Rcon(a(x)) = (Rc(a(x)),0,0,0) \). Here the commas define separation of each byte arranged in big endian format.

iv. \( Indicator\ vector \) representing a byte, say \( a(x) = x^4+x^3+1 = 25 \), is a 256x1 matrix with 1 only at 25th position and zeros elsewhere, i.e. the vector representing \( a(x) \) has 1 at the place corresponding to the numerical value of the byte and zero at all other positions in the matrix 0 to 255. Hence it will be of the form:

\[
Iv[a(x)] : [0\ 0\ 0\ 0\ \ldots\ 0\ 1\ 0\ 0\ \ldots\ 0]^T
\]

\( \uparrow 0 \ \uparrow 25 \ \uparrow 255 \)

**Brief description of Rijndael internals:** Rijndael has an elegant algebraic structure over \( F_{2^8} \). The input plain text or the output cipher text of block size of 128-bits is viewed as a 4x4 matrix of 16 bytes arranged in a column major format. Rijndael consists of an initial round of key addition (\( ak \)) followed by 10 iterations of round transformations for the key size of 128-bits. Each (except the last) round transformation function is composed of the four sub transformation functions: Byte Substitution or \( bs \), Row Shift or \( rs \), Mix Column or \( mc \) and Add Round Key or \( ak \). The last round transformation does not include the \( mc \) function.

**Byte substitution transformation:** \( bs \): This is the only non-linear transformation in the entire Rijndael structure. It operates independently on each byte using a substitution table (S-box). The S-box, which is invertible in nature, is composed of two transformations:

1. Taking multiplicative inverse of the desired byte in the finite field \( GF(2^8) \) with \( (x+1)=(03_{base \ 16}) \) as primitive element and \( g(x)=(x^8+x^4+x^3+x^1+1) \) as the defining irreducible polynomial. The element \( 0_{base \ 16} \) is mapped to itself.

2. Applying an affine transformation of \( x^6+x^5+x^1+1 \) equivalently \( 63_{base \ 16} \).

Thus, the byte substitution operation transforms a byte \( a(x) \) to \( bs(a(x)) \) as per the following relation. Let

\[
c(x) = a(x)^{-1}(mod\ g(x))
\]

\[
bs(a(x)) = (x^4 + x^3 + x + 1)^{} + c(x)(x^4 + x^3 + x^2 + x + 1)^{mod(x^8 + 1)}
\]

The inverse S-box is constructed by taking an inverse affine transform followed by a multiplicative inverse in the finite field \( F_{2^8} \).

1. \( c(x) = (x^2+1)^{-1}(mod\ g(x)) \)

2. \( bs(a(x))(x^6 + x^3 + x^{mod(x^8 + 1)}) \)

**Row shift transformation:** \( rs \): The 16 input bytes are arranged in a column major format of a 4x4 matrix. To achieve the desired confusion, a linear transformation \( rs \) is applied. Here, the bytes in each row of the matrix are given a cyclic left shift. For \( i = 1, 2, 3, 4 \) the bytes in the \( i \)-th row are circularly left shifted by \( (i-1) \) bytes.

The inverse of a row shift transformation is obtained by cyclically shifting the bytes in the reverse direction i.e. circularly right shifting 0, 1, 2, and 3 bytes in the first, second, third and fourth row of the 4x4 input matrix, respectively.
Mix column: $mc$: The linear transformation mix column provides the diffusion by mixing the bits of each column. The function $\beta(z)$, given below, operates on the input column by treating it as a degree three polynomial in $F_2[z]$. This polynomial is multiplied by a rotated version of a standard polynomial $m(z) \in F_2[z]$ given by
\[
m(z) = 02z^3 + 11z^2 + 09z + 14 \quad \text{and reduced modulo the polynomial } (z^4 + 1) \text{ in } F_2[z].
\]
Here the coefficients denote elements of $F_2$. It is known that the coefficients of $m(z)$ are so chosen that the result $\beta(z).m(z)$ is invertible modulo $(z^4 + 1)$ although this polynomial is reducible over $F_2$.

For example, a column of $mc$, $(a_0, a_1, a_2, a_3)^T$ is considered as:
\[
\beta(z) = a_3z^3 + a_2z^2 + a_1z + a_0 \in F_2[z]
\]
Then,
\[
m(z).\beta(z) = (03a_3 + 03a_2 + 01a_1 + 01a_0)z^6 + (03a_2 + 03a_1 + 01a_0)z^5
\]
\[
+ (03a_0 + 02a_3 + 01a_2 + 01a_1)z^4
\]
\[
+ (01a_0 + 02a_2 + 01a_1)z^3
\]
\[
+ (01a_0 + 02a_1)z + (02a_0)z^0
\]
\[
\mod(z^4 + 1)
\]
\[
m(z).\beta(z) = 02 03 01 01 | a_0
\]
\[
01 02 03 01 | a_1
\]
\[
01 01 02 03 | a_2
\]
\[
03 01 02 03 | a_3
\]

The inverse of Mix column transformation is similar to the forward operation with the only difference that the inverse of the fixed polynomial $i.e. [m(z)]^{-1}$ is used and it is given by
\[
[m(z)]^{-1} = 11z^3 + 13z^2 + 09z + 14
\]
Hence,
\[
[m(z)]^{-1} \cdot \beta(z) = 14 11 13 09 | a_0
\]
\[
13 09 14 11 | a_1
\]
\[
11 13 09 14 | a_2
\]
\[
13 09 14 11 | a_3
\]

Add Round Key: $ak$: In this function, the round key is added to the current byte as bit-wise exclusive OR. The XOR operation is the inverse of itself.

Modified Rijndael’s key expansion mechanism: The key expansion mechanism for 128-bit key size, in Rijndael is defined in the following manner.

The expanded key of $N_k(N_k+1)(=44)$ words is derived from the 4 words of the user defined key. The first $N_k (= 4)$ words, $W[0], ..., W[3]$ of the expanded key are filled with the user defined original cipher key bits. The subsequent key words for all $N_k \leq i < (N_k(N_k+1))$ i.e. $4 \leq i < 44$ alternatively $i \equiv 4, ..., 43$ are given by:
\[
W[i] = \begin{cases} 
W[i-N_k] \oplus \text{Rotbyte}(bs(W[i-N_k])) & \text{if } i \equiv 0 (N_k) \\
W[i-N_k] \oplus \text{Rcon}(i/N_k) & \text{if } i \equiv 0 (N_k)
\end{cases}
\]

We have modified the key expansion algorithm in the following manner: As the functions $bs(.)$ and $\text{Rcon}(.)$ transformations inherently operate on individual bytes of every input word, thus, a modified byte oriented version for key expansion algorithm can be derived. Therefore, for the present study with key size and block size of 128 bits and 10 cipher rounds, a total of 176 (= $4 \times (N_k(N_k+1))$) bytes from the 16 bytes (=128 bits) of the user defined key $k_n$ with $n = [0, ..., 15]$ are to be expanded.

First $4 \times N_k (=16)$ bytes, defined as $K^0_j := \{k_0, k_1, k_2, ..., k_{15}\}$ of the expanded key are filled with the original 128 user defined key bytes stored in big endian format. For subsequent rounds, the expanded key bytes at $n = [16, ..., 175]$ are given by the following relations:

i. when $n = 0$ (mod $4 \times N_k$), the four consecutive key bytes at $n$ to $n+3$ locations are obtained through:
\[
k_n = k_{n-16} \oplus bs(k_{n-3}) \oplus \text{Rcon}(n/16)
\]
\[
k_{n+1} = k_{n+1-16} \oplus bs(k_{n-2})
\]
\[
k_{n+2} = k_{n+2-16} \oplus bs(k_{n-1})
\]
\[
k_{n+3} = k_{n+3-16} \oplus bs(k_{n-4})
\]

ii. The subsequent expanded key bytes for a particular round i.e. from $(n+4)$th byte to $(n+15)$th byte of $k_n$ are obtained through:
\[
k_n = k_{n-16} \oplus k_{n-4}
\]

Alternatively, these expanded key bytes can be obtained in the form of round keys $K_i$ through the following relations with the original key bytes filled at $i = 0$ & $j = 0, ..., 15$ in $K^0_j$.

For $0 \leq i < 10$
\[
k_i^{10} = K_i^{0} \oplus bs(K_{13}^i) \oplus Rcon(i+1)
\]
\[
k_i^{11} = K_i^{1} \oplus bs(K_{14}^i)
\]
\[
k_i^{12} = K_i^{2} \oplus bs(K_{15}^i)
\]
\[
k_i^{13} = K_i^{3} \oplus bs(K_{12}^i)
\]
\[
k_i^{14} = K_i^{4} \oplus bs(K_{13}^i) \oplus Rcon(i+1)
\]
\[
k_i^{15} = K_i^{5} \oplus bs(K_{14}^i)
\]
\[
k_i^{16} = K_i^{6} \oplus bs(K_{15}^i)
\]
\[
k_i^{17} = K_i^{7} \oplus bs(K_{12}^i)
\]
\[
k_i^{18} = K_i^{8} \oplus bs(K_{13}^i) \oplus Rcon(i+1)
\]
\[
k_i^{19} = K_i^{9} \oplus bs(K_{14}^i)
\]
\[
k_i^{20} = K_i^{10} \oplus bs(K_{15}^i)
\]
\[
k_i^{21} = K_i^{11} \oplus bs(K_{12}^i)
\]
\[
k_i^{22} = K_i^{12} \oplus bs(K_{13}^i)
\]
\[
k_i^{23} = K_i^{13} \oplus bs(K_{14}^i)
\]
\[
k_i^{24} = K_i^{14} \oplus bs(K_{15}^i)
\]

Till now we have discussed briefly the internals of Rijndael algorithm. Now we are going to present the modified form of the $bs$ followed with indicator vector matrix representation of one complete round involving
all the four transformation functions namely: \(bs, rs, mc\) and \(ak\) in the subsequent sections.

**Modified byte substitution \(bs\) transformation:** The \(bs\) transformation, as stated in previous section comprises of two steps – first step is to calculate multiplicative inverse of the desired byte followed by the second step of an affine transformation. Let \(b_i \ (b_0, b_1, b_2, b_3, b_4, b_5, b_6, b_7)\) represents the bits of a byte as a vector in big endian format. In matrix form, the affine transformation component of the S-box can be expressed as:

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 \\
1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 \\
1 & 1 & 1 & 1 & 1 & 1 & 0 & 1 \\
0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\
0 & 0 & 0 & 1 & 1 & 1 & 1 & 1
\end{bmatrix}_{8 \times 8} \begin{bmatrix}
b_0 \\
b_1 \\
b_2 \\
b_3 \\
b_4 \\
b_5 \\
b_6 \\
b_7
\end{bmatrix}_{8 \times 1} = \begin{bmatrix}b_{0s} \\ b_{1s} \\ b_{2s} \\ b_{3s} \\ b_{4s} \\ b_{5s} \\ b_{6s} \\ b_{7s}\end{bmatrix}_{8 \times 1}
\]

The above matrix can be compactly represented as:

\[
B' = A \cdot B \oplus AF
\]

where, \(A = \begin{bmatrix}x^4 + x^3 + x^2 + x + 1\end{bmatrix}\) over \(F_2^8\)

and \(AF = \begin{bmatrix}x^6 + x^5 + x + 1\end{bmatrix}\) over \(F_2^8\)

The matrix representation of byte \(B\) can further be represented as product of two matrices: \(FF[8 \times 256]\) and \(Iv[256 \times 1]\). Each row of \(FF\) matrix represents the multiplicative inverse in bit vector form of the corresponding individual byte. \(Iv\) matrix, as described earlier, gives the indicator vector representation of the byte under consideration. Hence, the equation (1) transforms to:

\[
B' = A \cdot FF \cdot Iv \oplus AF
\]

The inverse byte substitution transformation can similarly be represented as:

\[
B = A^{-1} \cdot FF \cdot Iv \oplus AF^{-1}
\]

where, \(A^{-1} = \begin{bmatrix}x^6 + x^3 + x\end{bmatrix}\) over \(F_2^8\)

and \(AF^{-1} = \begin{bmatrix}x^2 + 1\end{bmatrix}\) over \(F_2^8\)

Here, we partially linearized the \(bs\) transformation.

In the next section we extend this formulation idea of \(Iv\) to recast the Rijndael round functions to represent mathematically as a simple \(Iv\) matrix relation.

**Recasting of Rijndael internals**

\[
\begin{align*}
\{x_{0i}^{r_i}, \ldots, x_{15}^{r_i}\} & \rightarrow \text{Round Functions} \\
\ (bs, \ rs, mc \ & \& \ ak) & \rightarrow \{x_{0i}^{r_i}, \ldots, x_{15}^{r_i}\} \\
\{k_{0i}^{r_i}, \ldots, k_{15}^{r_i}\} & \\
\end{align*}
\]

**Fig. 1:** Pictorial representation of an \(i\)-th round transformation function

The Fig. 1 gives the pictorial representation of an \(i\)-th round transformation function. We recast the cipher round with an abuse of notation in the following manner:

Let \(\mu_j = 1, 2, 3\) are the “operators” such that:

\[
\mu_1 = \mu = bs(a(x)), \\
\mu_2 = 2 \cdot \mu = x \cdot bs(a(x)) \mod g(x), \\
\mu_3 = 3 \cdot \mu = (x + 1) \cdot bs(a(x)) \mod g(x).
\]

These \(\mu_j\)'s correspond to the \(mc\) transformation of the \(bs\) transformed byte and their position in the matrix \(R\) corresponds to the \(rs\) transformation on the byte \(X\).

\[
\begin{bmatrix}
\mu_2 & 0 & 0 & 0 & \mu_4 & 0 & 0 & 0 & \mu_4 & 0 & 0 & 0 & \mu_4 & 0 & 0 & 0 & \mu_4 \\
\mu_6 & 0 & 0 & 0 & \mu_6 & 0 & 0 & 0 & \mu_6 & 0 & 0 & 0 & \mu_6 & 0 & 0 & 0 & \mu_6 \\
\mu_1 & 0 & 0 & 0 & \mu_1 & 0 & 0 & 0 & \mu_1 & 0 & 0 & 0 & \mu_1 & 0 & 0 & 0 & \mu_1 \\
\mu_5 & 0 & 0 & 0 & \mu_5 & 0 & 0 & 0 & \mu_5 & 0 & 0 & 0 & \mu_5 & 0 & 0 & 0 & \mu_5 \\
\mu_0 & 0 & 0 & 0 & \mu_0 & 0 & 0 & 0 & \mu_0 & 0 & 0 & 0 & \mu_0 & 0 & 0 & 0 & \mu_0 \\
\mu_3 & 0 & 0 & 0 & \mu_3 & 0 & 0 & 0 & \mu_3 & 0 & 0 & 0 & \mu_3 & 0 & 0 & 0 & \mu_3 \\
\mu_7 & 0 & 0 & 0 & \mu_7 & 0 & 0 & 0 & \mu_7 & 0 & 0 & 0 & \mu_7 & 0 & 0 & 0 & \mu_7 \\
\mu_2 & 0 & 0 & 0 & \mu_2 & 0 & 0 & 0 & \mu_2 & 0 & 0 & 0 & \mu_2 & 0 & 0 & 0 & \mu_2 \\
\end{bmatrix}
\]

\(R\) represented above seems to be a 16x16 matrix but actually is 4096 x 4096 with each of \(\mu_j\) as 256x256 matrix and each ‘0’ also represents a null matrix of size 256x256. Further, each row of \(\mu_j\) is an indicator vector representation of corresponding byte of \(mc\) operated S-box.

Thus, one round of Rijndael can completely be characterized as:

\[
x_i = R \cdot x_{i-1} \oplus k_{i-1}^{-1}
\]

where \(x_i = [x_0^i, \ldots, x_{15}^i]^T\): vector of 16 indicator vectors form 4096 x 1

\(x_{i-1} = [x_0^{i-1}, \ldots, x_{15}^{i-1}]^T\): vector of 16 indicator vectors form 4096 x 1

\(k_{i-1}^{-1} = [k_0^{i-1}, \ldots, k_{15}^{i-1}]^T\): vector of 16 indicator vectors form 4096 x 1

The output \(x_i\) does not result in an indicator vector.
CONCLUSION

The algorithm proposed in this paper can be successfully used to remodel the two-step byte substitution transformation to one step. Further, it is possible to represent one complete round of Rijndael using indicator vector matrix representation. The output vector $X^i$, so obtained deviates from the indicator vector representation. Finding a way of conversion of this byte vector $X^i$ so obtained, to an indicator vector form is still an open problem.
