Real ADE-equivariant (co)homotopy and Super M-branes

John Huerta∗, Hisham Sati†, Urs Schreiber‡

July 6, 2018

Abstract

A key open problem in M-theory is the identification of the degrees of freedom that are expected to be hidden at ADE-singularities in spacetime. Comparison with the classification of D-branes by K-theory suggests that the answer must come from the right choice of generalized cohomology theory for M-branes. Here we show that real equivariant cohomotopy on superspaces is a consistent such choice, at least rationally. After explaining this new approach, we demonstrate how to use Elmendorf’s theorem in equivariant homotopy theory to reveal ADE-singularities as part of the data of equivariant $S^4$-valued super-cocycles on 11d super-spacetime. We classify these super-cocycles and find a detailed black brane scan that enhances the entries of the old brane scan to cascades of fundamental brane super-cocycles on strata of intersecting black M-brane species. At each stage the full Green–Schwarz action functional for the given fundamental brane species appears, as the datum associated to the morphisms in the orbit category.

# Introduction

A homotopy theory (see Sec. A.2) is a mathematical theory in which the concept of strict equality is generalized to that of homotopy. A special case is higher gauge theory, where equality of higher gauge field configurations is generalized to that of higher gauge equivalence. Homotopy theory is extremely rich, involving a zoo of higher-dimensional structures and exhibiting a web of interesting and often unexpected equivalences, which say that very different-looking homotopy theories are, in fact, equivalent. One such equivalence is Elmendorf’s theorem (3.26). This says, roughly, that homotopy theory for equivariant homotopies is equivalent to another homotopy theory where no equivariance on homotopies exists anymore, but where instead extra structure appears on singularities, namely on the fixed point strata of the original group action.

String/M-theory (see Sec. 2) is also extremely rich, involving a zoo of higher-dimensional objects (branes) and expected to exhibit a web of interesting and often unexpected dualities, which say that very different-looking string theories are, in fact, equivalent. The most striking such duality is the one between all superstring theories on the one hand, and something with the working title M-theory on the other. Under this duality, “fundamental” or “perturbative” strings and branes, whose sigma-model description is equivariant with respect to certain finite group actions, are supposed to be related to “black” or “non-perturbative” branes located at the singular fixed points of this group action. This duality is crucial for M-theory to be viable at all, since realistic gauge force fields can appear only at these singularities (reviewed in Sec. 2.2). But with the mathematics of M-theory still elusive, the identification of the extra degrees of freedom of M-theory, that ought to be “hidden” at these singularities, has remained a key open problem.

We highlight that string theory and homotopy theory are closely related: every homotopy theory induces a flavor of generalized cohomology theories (see A.2), and a fundamental insight of string theory is that the true nature of the F1/Dp-branes (and the higher gauge fields that they couple to) is as cocycles in the generalized cohomology theory twisted K-theory [Wit98, FrWi99, MoWi00, EvSa06, Evs06], or rather real twisted K-theory on real orbifolds (“orientifolds”) [Wit98, Sec. 5.2], [Guk99, Hor99, DFM09, DMR13]. See Example A.25 below.

This suggests that the solution to the open problem of the elusive nature of M-branes requires, similarly, identifying the right generalized cohomology theory, hence the right homotopy theory, in which the M-branes (their charges) are cocycles. For the fundamental M2/M5-brane, we already know this generalized cohomology theory in the rational approximation: it is cohomotopy on superspaces in degree 4 ([Sa13, Sec. 2.5] [FSS15d, FSS16c], recalled below in Section 2.1). Hence the open question is: which enhancement of rational cohomotopy also captures the black M-brane located at real ADE-singularities?

Here we present a candidate solution: we set up equivariant cohomotopy on superspaces (Sec. 3.2) and show that (Sec. 4.3 and 5) under this identification, the equivalence of homotopy theories that is given by Elmendorf’s theorem translates into a duality in string/M-theory that makes the black branes at real ADE-singularities appear from the equivariance of the super-cocycle of the fundamental M2/M5-brane:

| G-equivarance | Elmendorf’s theorem | G-fixed points |
|---------------|---------------------|----------------|
| Fundamental M2/M5-branes on 11d superspacetime with real ADE-equivariant sigma-model | Theorem 6.1 | Fundamental F1/M2/M5-branes on intersecting black M-branes at real ADE-singularities |

Our main theorem [6.1] shows that enhancement of the fundamental M2/M5-brane cocycle from (rational) cohomotopy of superspaces to (rational) equivariant cohomotopy exists, and the possible choices correspond to fundamental branes propagating on intersecting black M-branes at real ADE-singularities. Part of this statement is a classification of finite group actions on super Minkowski super spacetime $\mathbb{R}^{10,1|32}$ by isometries. Our first theorem [4.3] shows that this classification accurately reproduces the local models for $\geq 1/4$-BPS black brane solutions in 11-dimensional supergravity.
We propose that this result may be understood as the **black brane scan**: we recall in Sec. 2.1 below, that for the **fundamental branes** (or “probe branes”: the consistent Green–Schwarz-type sigma-models) such a cohomological classification of species is famously known as the **old brane scan** [AETWS7 [Duff88], p. 15], recalled as Prop. 3.39 below. Careful consideration of higher symmetries leads to a completion to the **fundamental brane bouquet** [FSS13], indicated in Figure 2 below.

It has been an open problem (see [Duff99], p. 6-7; [Duff08]) to improve this “fundamental brane scan/bouquet” to a cohomological classification that includes the “black” brane species. Theorem 6.1 suggests that the missing **black brane scan** is obtained by enhancing to equivariant cohomology; see Sec. 2.2 for elaborations.

Here it may be noteworthy that the emerging picture of M-theory thus obtained exhibits the foundational paradigms of **Klein geometry** and of **Cartan geometry** (e.g. [CaSl09, Chapter 1]):

**(i) Klein geometry.** In the Erlangen program of [Klein1872] the basic shapes of interest in geometry are taken to be fixed loci of group actions on an ambient model space. Theorem 4.3 shows that, when the ambient space is taken to be $D = 11, N = 1$ super-spacetime, then the basic shapes in the Kleinian sense are precisely the black M-brane species and their bound states.

| General | Black M-brane species |
|---------|------------------------|
| Orbifold Klein geometry $\Gamma \backslash G/H$ | $(G_{ADE} \times \mathbb{Z}_2) \backslash \text{Iso}(k,1)_{\mathbb{R}^{10,1}} \backslash \text{Spin}(10,1)$ |
| super Poincaré group | cone with real ADE-singularity |
| $\mathbb{R}^{10,1}_{\mathbb{R}^{10,1}}$ | super Minkowski spacetime |

For example, the following picture (from Figure 1 below) illustrates the super orbifold Klein geometry that is the local model for M2-branes at an ADE-singularity intersecting an MO9-plane at a Hořava-Witten $\mathbb{Z}_2$-singularity (see Table 1 for a list of literature, and see Sect. 2 for discussion of the physics background):

![Diagram](image)

Our main Theorem 6.1 characterizes cocycles on these Klein geometries in equivariant super homotopy theory, with coefficients in the 4-sphere, equipped with analogous group actions.

---

1 One may try to organize some of the branes missing from the old brane scan by other than cohomological means, such as by BPS solutions to supergravity [DuLu92, DKL95]. We discuss this in Section 2.2.

2 From [Klein1872, Sec. 1]: “As a generalization of geometry arises then the following comprehensive problem: given a manifold and a group of transformations of the same; to investigate the configurations belonging to the manifoldness with regard to such properties as are not altered by the transformations of the group.”
By Example 3.49 below, these are, in particular, systems of maps from the fixed point strata of the singular super spacetime, to those of the (rational) 4-sphere, as indicated by the following picture:

Here the group actions on our coefficient 4-sphere on the right (defined below in Section 5.1) are those on the spacetime 4-sphere around a black M5-brane, we explain this in Section 2.2. In addition to the ADE-singularities captured by ADE-equivariance, the real structure (see Example A.25) reflects the presence of M-theoretic O-planes, such as the MO9 (Example 2.2). Each of the stratum-wise maps indicated in the above picture turns out to encode a super-cocycle that characterizes a fundamental brane species propagating on a given black brane singularity. Moreover, the compatibility relations in the datum of an equivariant cocycle makes the Green–Schwarz action functional for the corresponding sigma-model appear; this is explained in Section 6.2 below.

(ii) Cartan geometry. The geometry of Cartan1923 is the local-to-global principle applied to Klein geometry: the local model space of Klein is promoted to a moving frame that characterizes each tangent space of a curved Cartan geometry as compatibly identified with the local model space. Indeed, the geometry of supergravity is intrinsically Cartan geometric Lot90 EE12, and specifically 11d supergravity is equivalent to torsion-free super Cartan geometry modeled on \( R^{10,1|32} \) Cl94 Ho97. This generalizes to orbifold Cartan geometry (higher Cartan geometry Sch15 Wel17) locally modeled on orbifold Klein spaces.

The left half of the following picture illustrates a curved higher Cartan geometry locally modeled on the orbifold Klein geometry shown before.

This perspective of orbifold Klein geometry controlling its curved generalizations, via higher Cartan geometry, serves to conceptually explain how the equivariant cohomology of super-Minkowski spacetime itself, which we study here, may see so much of the structure of M-theory.
Table L. The list of symbols for the real ADE-singularities in 11d super spacetime, as they appear in the classification of Theorem 4.3 and Theorem 6.1, matched with pointers to selected references (out of many) in the physics literature, from which the established name of the corresponding brane species may be identified, as discussed in detail in Sec. 2.2.
Therefore, since Theorem 6.1 shows that equivariant cohomotopy locally, i.e. super tangent space-wise, captures M-brane physics, this suggests that, at least rationally, the generalized cohomology theory real ADE-equivariant 4-cohomotopy of superspaces (Sec. 5) serves as the missing definition of the concept of M-brane species also globally; in direct analogy to how the generalized (co-)homology theory K-theory is understood to provide the precise definition of the concept of D-branes:

| Objects | Cohomology theory |
|---------|-------------------|
| M-branes | Real ADE-equivariant Cohomotopy |
| D-branes | Real K-theory |

To support this, there must be:

1. a homotopy-theoretic formulation of the famous but informal idea of “compactifying M-theory on a circle” ([DHS13], see [Duff99], Sec. 6), such that
2. under this operation the cohomology theory degree-4 cohomotopy transmutes into the cohomology theory K-theory, matching how the M-branes are supposed to reduce to F1/Dp-branes under double dimensional reduction.

Indeed, in [FSS16a] it is shown that, rationally, (1) is exhibited by the Ext/Cyc-adjunction and then (2) follows, since 6-truncated twisted K-theory appears, rationally, in the cyclic loop space of the 4-sphere. In the companion article [BSS18] it is shown that the gauge enhancement of this result to the full, untruncated, twisted K-theory spectrum arises from the fiberwise stabilization of the unit of the Ext/Cyc-adjunction applied to the A-type orbispace of the 4-sphere (Def. 5.1 below).

In conclusion, equivariant rational cohomotopy of superspaces goes a long way towards capturing the folklore on the zoo of brane species; and of course the vast majority of discussions in the string theory literature is sensitive only to rational (non-torsion) effects, anyway. Nevertheless, as shown by the classification of D-branes in string theory by K-theory, a non-rational lift of this cohomology theory will be necessary to fully capture M-brane physics. For the moment we leave this as an open problem. However, we emphasize that detailed study of the rational theory will provide the crucial clues for passing beyond the rational approximation. This is because we are not just faced with one rational cohomology theory in isolation, but with a web of rational cohomology theories that are subtly related to each other and which collectively paint a large coherent picture:

1. **Fundamental M2/M5-branes** [Sa13, Sec. 2.5] [FSS15]: The M2/M5-brane cocycle is, rationally, in equivariant cohomotopy.
2. **Black M-branes** (Thm. 6.1): The corresponding ADE-equivariant enhancement exhibits the black M-branes at ADE-singularities.
3. **M/IIA duality** ([FSS16a]): The corresponding double dimensional reduction is cohomological cyclification and yields the F1/Dp(p ≤ 4)-cocycle in type IIA string theory.
4. **Gauge enhancement** [BSS18]: The corresponding lift through the fiberwise stabilization of the Ext/Cyc-adjunction yields the gauge enhancement to the full type IIA F1/Dp cocycle in twisted K-theory (rationally).
5. **IIA/IIB T-duality** [FSS16b]: The further double dimensional reduction of that, via further cyclification, exhibits T-duality between the cocycles of the type IIA and type IIB F1/Dp-branes.
6. **M/HET duality** [FSS18] [SS18]: The higher analog of this Fourier-Mukai transform applied to the M2/M5-brane cocycle itself yields a higher T-duality of a 7-twisted cohomology theory that connects to the Green–Schwarz mechanism of heterotic string theory.

\[\text{While such a derivation of K-theory from M-theory is suggested by the title of [DMW03], that article only checks that the behavior of the partition function of the 11d supergravity C-field is compatible with the a priori K-theory classification of D-branes.}\]
This web of dualities between various rational cohomology theories accurately captures a fair bit of the web of dualities expected in string/M-theory. Since every non-rational lift of the cohomology theory for M-branes will have to lift that entire web of dualities, this puts strong conditions on such a lift, considerably constraining the freedom in lifting an isolated rational cohomology theory.

We read all this as indication that our analysis narrows in on the correct generalized cohomology theory classifying super M-branes, and thus, at least in part, on the elusive definition of M-theory itself.

The outline of this article is as follows. We start by providing novel consequences for the understanding of M-branes in Sec. 2. In particular, in Sec. 2.2 we explain the physical meaning of Theorem 6.1 by comparison to the story told in the informal string theory literature, the main points of which we streamline there and in Sec. 2.1. Sec. 3 provides the proper mathematical setting for our formulation. After collecting the concepts and techniques of equivariant homotopy theory in Sec. 3.1 we provide an extension to the super setting in Sec. 3.2, which we hope would also be of independent interest. Our main results on Real ADE-Equivariant cohomotopy classification of super M-branes are given in Sections 4, 5, and 6, where we discuss equivariant enhancements (according to Example 3.49) of the M2/M5-brane cocycle (Prop. 3.43). Group actions on the 4-sphere model space, as well as the resulting incarnation of the 4-sphere as an object in equivariant rational super homotopy theory are given in Sec. 5. In Sec. 4 we describe real ADE-actions on 11-dimensional superspacetime $\mathbb{R}^{10,1|32}$ and their fixed point super subspaces. The corresponding superorbifolds are a supergeometric refinement of the du Val singularities in Euclidean space. Having discussed real ADE-actions both on $\mathbb{R}^{10,1|32}$ (Sec. 4) and on $S^4$ (Sec. 5), the possible equivariant enhancements of the M2/M5-brane cocycle that are compatible with these actions are studied in Sec. 6.

The final statement is Theorem 6.1. This involves three ingredients:

- In Section 4 we classify group actions on the domain space, namely on $D = 11$, $N = 1$ super-Minkowski spacetime, which have the same fixed point locus as an involution and are at least $1/4$-BPS. If orientation-preserving, then these actions are by finite subgroups of SU(2), hence finite groups in the ADE-series.
- In Section 5 we discuss real ADE-space structure on the coefficient space, namely the rational 4-sphere. This establishes the cohomology theory ADE-equivariant rational cohomotopy in degree 4 to which the M2/M5-cocycle enhances.
- Finally in Section 6 we discuss the possible equivariant enhancements of the M2/M5-cocycle itself, mapping between these real ADE-spaces.

Finally, in the appendices we provide our spinorial conventions (Section A.1) as well as some basic notions from homotopy theory and cohomology theories (Section A.2).

2 Understanding M-Branes

We now provide an informal discussion, that is meant to put the formal results of Sections 4, 5, and 6 into the perspective of string/M-theory. For completeness and to highlight the concepts involved, we first quickly review a perspective on branes within string/M-theory. Then in Section 2.1 we briefly recall the mathematical classification of fundamental branes, which is the conceptual background for the starting point of our mathematical discussion in Section 3.2. Finally, Section 2.2 concerns the physics interpretation of our classification result from Sections 4, 5, and 6: we walk there through selected examples from the informal string/M-theory literature (as listed in Table L) and point out how to match, item by item, the entries of our classification Tables 1 and 2 to structures in the folklore on M-branes.

To start with, the concept of fundamental brane is the evident higher-dimensional generalization of the concept of a fundamental particle: a precise concept of fundamental particles, in turn, is obtained by combining perturbative quantum field theory with an insight called the worldline formalism (reviewed in [ScSc95, Sch96]). Here, the trajectories of fundamental particles in some spacetime $X$ are represented by maps from the abstract worldline of the particle, modeled by a 1-manifold $\Sigma_1$, to $X$

\[ \Sigma_1 \quad \xrightarrow{\phi} \quad X \]

The physically realizable particle trajectories are characterized as being the local extrema of a certain non-linear functional on the space of all these maps, the action functional. This has two contributions:

(i) The first contribution is that of the proper volume of $\phi$, as measured by the pseudo-Riemannian metric on $X$. This encodes the forces that a background field of gravity exerts on the particle, it is known as the Nambu-Goto action functional.

(ii) The second contribution encodes the remaining forces felt by the particle, exerted by further background fields. Notably, if the particle is charged under an electromagnetic field encoded by a differential 2-form $\mu_2$ on $X$ (the Faraday tensor), then the corresponding contribution to the action functional is the holonomy functional of a principal connection whose curvature 2-form is $\mu_2$. If $X$ is Minkowski spacetime, then this connection is given by a differential 1-form $\Theta_1$ on $X$ (the vector potential) and the holonomy functional is just the integration of $\Theta_1$ along $\phi$. This is the simplest example of what is called a WZW term in an action functional.

Hence, a fundamental charged particle is characterized by an action functional which is the integration over the particle’s worldline of a differential 1-form $L_1$ (the Lagrangian density) which, just slightly schematically, reads:

\[ L_1 = \text{vol}(\phi)_{\text{NG}} + \Theta_1(\phi)_{\text{WZW}} \xrightarrow{d} \mu_2. \]

The Mellin transform of these action functionals yields distributions in two variables, called Feynman propagators, which may be interpreted as the probability amplitude for a quantum fundamental particle to come into an accelerator experiment on a fixed asymptotic trajectory, and emerge on the other end on some fixed asymptotic trajectory, without interacting, in between, with anything. More generally, given a finite graph, a product of distributions may be assigned to it, with one Feynman propagator factor for each edge. These products turn out to be well defined and unique away from coincident vertices, and may be extended to the locus of coinciding vertices. The choice involved in these extensions of distributions is called (re-)normalization. The resulting distribution is called the Feynman amplitude associated with the graph.

If the graph has external edges, this may be interpreted as the probability amplitude for some number of quantum fundamental particles to come into an accelerator experiment on given asymptotic trajectories,

---

4Contrary to wide-spread perception, perturbative quantum field theory, such as pertaining to the standard model of particle physics, has a perfectly rigorous mathematical formulation, going back to [EG73], see e.g. [Sch18].
interacting with each other, as determined by the shape of the graph, and emerge on the other side on some given asymptotic trajectories. The *Feynman perturbation series* is the sum over all graphs of these Feynman amplitudes, as a formal power series in powers of the number of loops of the graphs. This, finally, may be interpreted as the probability amplitude that may be compared to experiment, describing an arbitrary scattering process of several quantum fundamental particles.

What is striking about this worldline formulation of perturbative quantum field theory is that it immediately suggests a tower of possible deformations: it is compelling, at least mathematically, to investigate the variants of this prescription where 1-dimensional graphs are replaced by \((p+1)\)-dimensional manifolds \(\Sigma_{p+1}\), where hence the particle trajectories are replaced by maps out of this abstract *worldvolume* of dimension \(p + 1\)

\[
\begin{array}{ccc}
\Sigma_{p+1} & \overset{\phi}{\rightarrow} & X \\
p\text{-brane trajectory} & & \text{spacetime}
\end{array}
\]

and where, finally the action functional is replaced by the integral of a suitable \((p + 1)\)-form

\[
L_{p+1} := \text{vol}_{p+1} + \Theta_{p+1} \overset{d}{\rightarrow} \mu_{p+2}
\]

This is naturally thought of as, possibly, producing probability amplitudes for higher dimensional fundamental objects to scatter off of each other. For \(p = 1\) these objects look like strings (whence the name); for \(p = 2\) they look like membranes. Hence for general \(p\) one speaks of *fundamental \(p\)-branes* \cite{DIPSS88}. Moreover, at least for \(p = 1\) there is a good candidate of what may replace the sum over all graphs: since 2-dimensional surfaces have a nice classification by genus and punctures, there is a good mathematical definition of a *string perturbation series*, deforming the above concept of the Feynman perturbation series. The study of this string perturbation series, thought of as a deformation of the Feynman perturbation series, is the subject of *perturbative String theory* (e.g. \cite{Wit15}).

Despite their immense successes, both the Feynman perturbation series as well as the string perturbation series have a severe conceptual problem in their very perturbativeness. Namely, while one would like to interpret the result of these perturbation series as *numbers*, characterizing concrete probability amplitudes that may be compared to measurement results, mathematically they are not numbers but just formal power series. Worse, simple arguments show that in all cases of interest, the radius of convergence of these formal power series *vanishes* (e.g. \cite[Sec. 1]{Sus05}). This means that Feynman/string perturbation theory provides no reason why it would make sense to sum up the first few terms of the perturbation theory and regard that as a decent approximation to experiment. Sometimes, notably for computations in QED, it does happen to produce excellent agreement with experiment. But sometimes it does not (as in much of QCD) and besides trial and error and experimental experience, there is no mathematical reason to tell. Hence the perturbativeness of fundamental particles and of fundamental strings is as much their intrinsic nature as it is their fatal shortcoming. The understanding of non-perturbative effects in quantum field theory such as quark confinement, hence existence of ordinary baryonic matter, is a wide open *millenium problem* \cite{ClayMP}.

In view of this, it is noteworthy that perturbative String theory exhibits concrete hints as to the nature of its non-perturbative completion. Notably, one finds \cite{DHSS7} that when the fundamental membrane mimics
a fattened fundamental string by wrapping around a small circle fiber of spacetime (double dimensional reduction), then the volume of that circle fiber is proportional to the strength of the fundamental string’s interactions. Read the other way around, this says that the fundamental string at strong coupling, hence beyond perturbation theory, should be nothing but the fundamental membrane. This led to the speculation that a non-perturbative version of perturbative string theory does exist and is embodied by M(embrane)-theory [Tow95, Wit95a], even if its actual nature remains elusive. Namely, there is no straightforward way to generalize the summation over all 1-dimensional graphs beyond a summation over surfaces to a summation over higher dimensional manifolds, because there is no classification parameter for higher dimensional manifolds, that could organize such a sum as a formal power series. Therefore, a potential Membrane theory, along the above lines, if it makes sense at all, must be more subtle than being a direct variant of perturbative string theory, which itself is a direct variant of the Feynman perturbation theory of fundamental particles. This subtlety is the reason for the name “M-theory”: this is a non-committal shorthand for “Membrane theory”, to beware that if a concept of fundamental membranes makes sense, then its relation to fundamental strings must be more subtle than that of the relation of fundamental strings to fundamental particles.

Evidence for M-theory had been actively accumulated up to just around the turn of the millenium, see [Duff99B]; then it waned, the community getting distracted by other topics:

> We still have no fundamental formulation of “M-theory” - Work on formulating the fundamental principles underlying M-theory has noticeably waned. […] If history is a good guide, then we should expect that anything as profound and far-reaching as a fully satisfactory formulation of M-theory is surely going to lead to new and novel mathematics. Regrettably, it is a problem the community seems to have put aside - temporarily. But, ultimately, Physical Mathematics must return to this grand issue. [Moore, Strings2014, Sec. 12]

This may remind one of an old prophecy which suggests that unraveling the true nature of string theory, hence of what came to be called M-theory, will require developments that become available only in the 21st century. One development that the new millenium has brought is the blossoming of homotopy theory into an immensely rich (see for instance [Rav03, HHR09]), powerful (Lu09-) and foundational (Sh17) subject. Above we have shown that in homotopy theory one finds curious classifications, whose entries we have labeled an immensely rich (see for instance [Rav03, HHR09]), powerful (Lu09-) and foundational (Sh17) subject. The former has meanwhile been found. This is exactly what we see appear in Theorem 6.1, via Prop. 6.11.

### 2.1 The fundamental brane scan

Here we informally recall the some background on the cocycle $\mu_{M2/M5}$ for the fundamental M2/M5-brane, which is the starting point of the analysis to come in Prop. 3.43, and indicate its place in a general cohomological classification of fundamental branes: the fundamental brane bouquet in Figure 3 below.

An early indication that homotopy theory plays a deep role in string theory was, in hindsight, the joint success and failure of the old brane scan (recalled as Prop. 3.39). Namely, via a sequence of somewhat involved arguments, it was eventually found that for fundamental branes on a supergravity background to be compatible with local supersymmetry, the form $\mu_{p+2}$ in (3.39) had to be a non-trivial cocycle in the supersymmetry super Lie algebra cohomology of super-space time $\mathbb{A}_{10889}$. The corresponding Lagrangians

---

5. It may be worthwhile to recall that, in mathematics, it is not unusual to postulate the existence of certain theories before one actually knows about their nature. Famous historical examples include the theory of motives or the theory of the field with one element. The former has meanwhile been found.

6. [HoWi95, p. 1]: “As it has been proposed that this theory is a supermembrane theory but there are some reasons to doubt that interpretation, we will non-committedly call it the M-theory, leaving to the future the relation of M to membranes.”

7. [Wit95c, p. 2]: “M stands for magic, mystery, or membrane, according to taste.”

8. [Wit03]: “Back in the early ’70s, the Italian physicist, Daniele Amati reportedly said that string theory was part of 21st-century physics that fell by chance into the 20th century. I think it was a very wise remark. How wise it was is so clear from the fact that 30 years later we’re still trying to understand what string theory really is.”

9. In [Sor99, Sor01] it is shown that the traditional derivation of the Green–Schwarz-type sigma-models (3.3), is clarified drastically if one takes the worldvolume $\Sigma_{p+1}$ to be a supermanifold locally modeled on the relevant BPS super subspace $\mathbb{R}^{p,1N} \hookrightarrow \mathbb{R}^{10,1|32}$. This is exactly what we see appear in Theorem 6.1 via Prop. 6.11.
are the Green–Schwarz-type Lagrangians, which in Prop. \[6.10\] we have seen to be just the super volume forms (hence the “super Nambu-Goto Lagrangians”\[10\])

\[
L^\text{GS}_{p+1} := \begin{array}{c}
\text{vol}_{p+1} + \Theta_{p+1} \\
\text{NG} + \text{WZW} \\
s\text{vol}_{p+1}
\end{array} \rightarrow d \rightarrow \mu_{p+2}
\]

These cocycles $\mu_{p+2}$ are what the (old) brane scan \[DuffSS\] classifies:

| $p$ | $d+1$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----|-------|---|---|---|---|---|---|---|---|---|----|
| 10+1|       | $\mu_{M2}$|   |   |   |   |   |   |   |   |    |
| 9+1 |       | $\mu_{I1}$| $\mu_{NS5}$|   |   |   |   |   |   |   |    |
| 8+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 7+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 6+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 5+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 4+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 3+1 |       | *           | *           |   |   |   |   |   |   |   |    |
| 2+1 |       | $\mu_{F1}^{D=3}$|       |   |   |   |   |   |   |   |    |

Table B. The Old Brane Scan classifies the non-trivial Spin-invariant super $(p+2)$-cocycles on super Minkowski spacetimes, for $p \geq 1$, see Prop. \[3.39\] for details. Via the associated Green–Schwarz-type Lagrangian densities\[3\] these cocycles correspond to those fundamental super $p$-branes propagating in $D$-dimensional super spacetimes, that do not carry (higher) gauge fields on their worldvolume. The completion of the old brane scan to the remaining branes and various further details is the fundamental brane bouquet, parts of which is shown in \[Figure 3\].

This scan does discover the brane species that have been argued for by various other means. For example, the entry $\mu_{M2}$ at $D = 11$, $p = 2$ in the old brane scan reflects the existence of the fundamental super membrane which was mentioned above, now known as the M2-brane, whose Green–Schwarz Lagrangian\[3\] we see below in the proof of Prop. \[6.10\]. Similarly, the old brane scan shows that and why there is a fundamental superstring, Example \[3.40\] as well as a 5-brane propagating in 10d super spacetime, just as earlier found with rather different methods. This suggests that super Lie algebra cohomology might be part of the missing mathematical formulation of the elusive foundations of string/M-theory. But this is a partial success only: a glorious insight associated with the “second superstring revolution” says that there should be more brane species than the old brane scan shows, and that jointly the enlarged system of brane species in various super spacetimes exhibits subtle equivalence relations known as dualities.

In \[FSS13\] it was pointed out that one may retain the foundational promise of the old brane scan, while improving it to include also all these new brane species, if one passes from super Lie algebras to their homotopy theoretic incarnation, called super strong homotopy Lie algebras or super $L_\infty$-algebras, for short. In fact, this generalization emerges naturally from a closer look at the nature of cohomology on ordinary (super) Lie algebras: it is a familiar fact that every 2-cocycle $\mu_2$ on a (super) Lie algebra classifies a central extension. For example the type IIA superspacetime carries a Spin-invariant 2-cocycle $\mu_{D0} = \bar{\psi} T^{10} \psi$, whose central extension is $D = 1, \mathcal{N} = 1$ super Minkowski spacetime:

\[10\] In the spirit of this physics section, we are deliberately suppressing notation for pullback of differential forms in these expressions, in order to bring out conceptual meaning of these formulas; see instead Section \[6.2\] for precise details.
Since $\mu_{D0}$ is the cocycle that defines the fundamental super D0-brane, and since informal string theory folklore has it that the the above extension may be understood the condensation of D0-branes, it is natural to ask whether the other cocycles in the old brane scan correspondingly define extensions of sorts.

In order to see how this could work, one observes that in the rational super homotopy theory, a 2-cocycle as above is equivalently a map, namely a map of the form $\mathbb{R}^{9,1|16+\text{I}_6}$, and for every map in homotopy there is the corresponding homotopy fiber. Inspection shows that for a 2-cocycle, this is just the corresponding central extension

$$\mathbb{R}^{10,1|32} \xrightarrow{\mu_{D0} = \overline{\psi}\Gamma^{10}\psi} \mathbb{R}^{9,1|16+\text{I}_6}.$$ 

With this perspective, now it is clear what the generalization is: for instance, given the string cocycle $\mu_{F1} = \frac{i}{2} \overline{\psi}\Gamma_{a1a2}\psi \wedge e^{a1} \wedge e^{a2}$, its homotopy fiber is not a super Lie algebra anymore, but a higher super Lie algebra, namely a super Lie 2-algebra (see [BH11] for exposition). Following established terminology for the bosonic analogue of this construction (see [FSS12], appendix) for details and further pointers, this is called the superstring Lie 2-algebra, and denoted string$_{\text{IIA}}$.

$$\mathbb{R}^{9,1|16+\text{I}_6} \xrightarrow{\mu_{F1} = \frac{i}{2} \overline{\psi}\Gamma_{a}\psi \wedge e^{a}} \mathbb{R}^{3|2}.$$ 

But, of course, the concept of super Lie algebra cohomology generalizes from plain super Lie algebras to super $L_\infty$-algebras. Hence we may now ask whether the higher extension of super-spacetime by the super string Lie 2-algebra carries further Spin-invariant cohomology classes. And indeed it does carry non-trivial Spin-invariant cocycles precisely for all the previously missing branes, namely super D-branes of type IIA:

$$\mathbb{R}^{9,1|16+\text{I}_6} \xrightarrow{\mu_{D(2p)} = \overline{\psi}\Gamma_a \psi \wedge e^{a}} \mathbb{R}^{2p+2}.$$ 

As before, these cocycles are reflected in the homotopy fibers that they induce, which are now super Lie $2p+1$-algebras, which, following the emerging pattern, we denote by $\text{d}2p\text{brane}$.

By proceeding in this fashion, one finds that as soon as super spacetime is regarded in super homotopy theory, there is, potentially, a whole bouquet of iterative invariant higher central extensions emerging from it, each corresponding to a fundamental brane species. In fact, as we saw with the D0-brane cocycle at the beginning, super spacetime itself may emerge from the existence of super 0-branes this way. This naturally leads one to look for a possible “root” of the fundamental brane bouquet. The simplest non-trivial super spacetime is the $D = 0$, $\mathcal{N} = 1$ super spacetime, also known as the superpoint. Regarding the superpoint in super homotopy theory, the bouquet of higher invariant central extensions that emerges out of it may be shown to be the completion of the old brane scan to the full fundamental brane bouquet. Parts of this is shown in Figure 3
Figure 3. The fundamental brane bouquet. The rational homotopy theory of superspaces (Def. 3.30) contains a god-given object: the superpoint $\mathbb{R}^{0|1}$. The diagram shows part of the web of higher rational superspaces that appears when, starting with the superpoint, one iteratively applies the operations of 1) doubling fermions and 2) passing to higher extensions invariant with respect to automorphisms modulo R-symmetry. What appears are, first, the super-Minkowski spacetimes (Def. 3.37) of the dimensions shown (see Example 3.37). These carry invariant 3-cocycles that correspond to the various species of fundamental string (i.e. the fundamental 1-branes) in the way reviewed above in Sec. 2.1. The higher extensions classified by these string-cocycles, shown by the name of the corresponding string species in the diagram, carry, in turn, further higher cocycles, these now corresponding to the D-branes and the M2-brane in their incarnation as fundamental or probe branes. This process climbs up to a cocycle for the fundamental M5-brane on the higher extension classified by the cocycle for the fundamental M2-brane on 11d super-Minkowski spacetime. By homotopical descent [FSS15b], this is equivalently the datum of a single 4-sphere valued cocycle on 11d super-Minkowski spacetime: the unified M2/M5-brane cocycle in rational super cohomotopy, from Prop. 3.43:

$$\mathbb{R}^{10,1|32} \overset{\mu_{M2/M5}}{\longrightarrow} S^4.$$ 

The brane bouquet climbs up to the fundamental membrane on 11-superspacetime, and then exhibits the emergence of a further 5-brane on top of that. By homotopical descent, as explained in detail in [FSS15b], these two iterative higher central extensions unify to a single cocycle on 11d super-spacetime, albeit no longer in ordinary cohomology, but in cohomotopy (Example A.25), as controled by (at least the rational
image of) the complex Hopf fibration (Def. A.10):

\[
\begin{array}{c}
\text{m2brane} \\
\downarrow \mu_{M5}
\end{array}
\begin{array}{c}
\mu_{M5}/M5
\end{array}
\begin{array}{c}
S^7
\end{array}
\text{quaternionic Hopf fibration}
\begin{array}{c}
\downarrow \mu_{M2}/M5
\end{array}
\begin{array}{c}
\Rightarrow
\end{array}
\begin{array}{c}
\mu_{M2}/M5 \rightarrow S^4
\end{array}
\begin{array}{c}
\downarrow \nonumber
\end{array}
\begin{array}{c}
\Rightarrow
\end{array}
\begin{array}{c}
\text{BSU}(2)_R
\end{array}
\Rightarrow
\begin{array}{c}
\in \text{Ho}\left(\text{SuperSpaces}_R\right).
\end{array}
\]

This is the fundamental M2/M5-cocycle \( \mu_{M5/M5} \), that in Prop. 3.43 is the starting point for our discussion of equivariant enhancement of fundamental brane cocycles.

### 2.2 The black brane scan

Here we informally recall aspects of the story of black branes, and then provide a list of commented pointers to statements in the string theory literature, that serve to support the interpretation of Theorem 4.3 and Theorem 6.1 as providing a precise definition and black brane scan-classification of bound states of black and fundamental branes in M-theory.

| Black brane Species | Example |
|---------------------|---------|
| MO9                 | 2.2     |
| M5                  | 2.3     |
| MW                  | 2.4     |
| M2                  | 2.5     |
| MK6                 | 2.6     |
| M5\_ADE             | 2.7     |
| 3/2 M5              | 2.8     |
| M1                  | 2.9     |
| NS1\_H              | 2.10    |

There is a curious analogy between fundamental particles and gravitational singularities: the black hole uniqueness theorems ("no hair theorems") of general relativity (see [Maz01, HoIs12]) state that isolated black hole spacetimes in equilibrium are completely characterized by just a handful of parameters; namely their mass, charge and spin (angular momentum). These are of course also the quantum numbers that characterize fundamental particles. Since, moreover, a black hole is a homogeneous spacetime, except for a pointlike singularity (or rather the 1+1-dimensional worldline of a point removed from spacetime, where it would become singular, if the point were to be included), it is natural to wonder if there is a secret relation between fundamental particles and black holes (see [Duff99B, Sec. 5]).

In superstring theory this analogy becomes stronger: on the one hand, there is a zoo of fundamental \( p \)-branes for various values of \( p \) and in various spacetime dimensions, as discussed above. On the other hand, the equations of motion of supergravity in these dimensions admit homogeneous solutions which are much like black holes in 4d gravity, but whose singular locus is \( p + 1 \)-dimensional, for specific values of \( p \); these are called black \( p \)-brane solutions of supergravity [DuLu92, Gue92, DuLu93, DKL95]. Strikingly, one finds that, essentially, for each fundamental \( p \)-brane sigma-model there is a corresponding black \( p \)-brane solution of supergravity which shares the same few defining parameters.

In particular, one may therefore consider the quantum fluctuations of fundamental \( p \)-branes that are aligned close to the singularity of their own black \( p \)-brane analog: the result are conformal field theories on asymptotically anti-de Sitter spacetimes ([BIDu88, DuSu88], see [Duff99A, Sec. 5], [PST99]). This most intimate relation between fundamental \( p \)-branes and black \( p \)-branes has (later) come to be famous as the AdS/CFT correspondence (see [Duff99B, Sec. 6]).

For these reasons, much of the informal literature in string theory terminologically blurs the distinction between fundamental \( p \)-branes and black \( p \)-branes, tacitly anticipating a working \( M \)-theory where it should make sense to, somehow, closely relate macroscopic solutions of classical supergravity with fundamental quantum objects. While all evidence indeed points to there being a unified perspective on these two phenomena, precise details on the conceptual relation have been emerging only gradually. The precise unification of fundamental and black \( p \)-brane aspects in Theorem 6.1, mediated via the discussion in Section 6.2, could serve to clarify the situation.
Concretely, asymptotically close to their horizon, the $>1/4$-BPS black $p$-brane spacetimes are all Cartesian products of an anti-de Sitter spacetime with a free discrete quotient of the sphere around the singularity, such that the result is a warped metric cone over the $p$-brane singularity, as shown here ([FF98] MedFig+09):

$$\begin{array}{|c|c|}
\hline
\text{Near horizon spacetime} & \text{anti-de Sitter spacetime} \\
\hline
\text{Metric in horospheric coord.} & \text{Metric in natural coord.} \\
\hline
\frac{R^2}{2} ds^2_{\mathbb{R}^p,1} + \frac{R^2}{2} dz^2 + ds^2_{S^{D-p-2}} & \frac{r^n}{T} ds^2_{\mathbb{R}^p,1} + \frac{\ell^2}{r^2} dr^2 + \ell^2 ds^2_{S^{D-p-2}} \\
\hline
\text{Causal chart} & \text{transversal space $\mathbb{R}^{D-p-2}\setminus\{0\}$} \\
\hline
\end{array}$$

The standard causal chart shown in the middle of (5) exhibits that the tangent spaces at the singularity (if it were to be included in the underlying spacetime manifold) are naturally identified with

$$T_{\text{sing}} \simeq_{\mathbb{R}} \mathbb{R}^p,1 \oplus \mathbb{R}^{D-p-2}$$

where the $G$-action fixes the origin in the transversal space $\mathbb{R}^{D-p-2}$, hence in total fixes the black $p$-brane singularity. This is just the (super) tangent space-wise situation (45) that Theorem 4.3 is concerned with. This way, for $G \neq \{e\}$ one may think of the black $p$-brane as sitting at a conical singularity [AFFHS98] [MP99].

Indeed, the standard computations of BPS black $p$-brane solutions in supergravity all proceed, eventually, by reducing a computation of Killing spinor fields on a curved supergravity spacetime, to a computation of spinors on one tangent space that are fixed by an involution, or, for intersecting branes, by several involutions (e.g. [Gau97] (4), (8), (11)), just as in Prop. 4.7 below, or, more generally, by larger finite ADE-groups [MedFig+09], [MedFig09] Sect. 8.3], as in our Prop. 4.15 below. We may hence view Theorem 4.3 below as a converse to these observations, saying that indeed the spectrum of black $p$-brane species is entirely determined super tangent space-wise. We suggest that it is useful think of this as exhibiting a higher form of the paradigm of super Cartan geometry, as indicated in Section 1, in line with the result of [CL94] [Ho97] [POS17], that the equations of motion of supergravity themselves are implied by the super torsion constraint, hence, via [Gui65], by the requirement that the infinitesimal neighborhood of every point in super spacetime looks super-metrically like the the model super-Minkowski tangent spacetime.

Notice how the singularity itself is not actually part of spacetime in (5): the singularity would be at $r = 0$, which is excluded from the spacetime manifold, since classical (super)gravity is not defined on singular spaces, it only sees everything right outside the singularities. But the brane that is supposed to sit there at the singularity is meant to be part of the elusive M-theory, of which 11d supergravity is meant to be just some approximation. There are a multitude of indirect informal arguments that in full M-theory some extra physical degrees of freedom do appear at singularities ([AcWi01], [Ach02] Sec. 3], [AtWi03], see [AcGu04] for review of the folklore). One such indirect argument we recall as Example 2.6 below. Notice also that some singularities that are supposed to appear in M-theory do not have a supergravity description at all, see Example 2.2 below. By the nature of these arguments, it seems plausible that identifying the missing M-theoretic degrees of freedom at these singularities goes a long way towards identifying the elusive M-theory itself.
This basic background on black M-branes already serves to illuminate the role of the 4-sphere as coefficient object for measuring M-brane charge: by Prop. 3.43 and the discussion in Section 2.1, we know that the 4-sphere has the correct rational homotopy type for measuring fundamental M-brane charge. What governs this is really the fact (4), that the 4-sphere participates in the rational image of the quaternionic Hopf fibration \( S^7 \to H \to S^4 \) (Def. A.10). But notice that, by (5), the two spheres involved here are exactly the unit spheres around the singularities in the near horizon geometries of the single M2-brane and of the M5-brane:

| Black brane | Near horizon geometry | Causal chart |
|-------------|-----------------------|-------------|
| M2          | AdS\(_4 \times S^7\)  | \(R^{2,1} \times R_+ \times S^7\) |
| M5          | AdS\(_7 \times S^4\)  | \(R^{5,1} \times R_+ \times S^4\) |

Hence, in the spirit of Dirac charge quantization (see [Fre00, Sec. 2]), the coefficient space \( A \) for the generalized cohomology theory (Def. A.24), which measures the presence of units of M-brane charge, should rationally be a 4-sphere, and should in addition have homotopy groups \( \pi_4(A) \cong \mathbb{Z} \) (for measuring the integer charge carried by M5-branes) and \( \pi_7(A) \cong \mathbb{Z} \) (for measuring the integer charge carried by M2-branes). But the evident choice for this is just the actual 4-sphere, \( A = S^4 \): this measures the presence of a single M5-brane by the identity map on the 4-sphere encircling it

\[
\text{AdS}_7 \times S^4 \xrightarrow{pr_2} S^4 \xrightarrow{id} S^4, \quad [id] = 1 \in \mathbb{Z} \cong \pi_4(S^4)
\]

and measures the presence of a single M2-brane by way of the quaternionic Hopf fibration \( H \) (Def. A.10) from the 7-sphere encircling it:

\[
\text{AdS}_4 \times S^7 \xrightarrow{pr_2} S^7 \xrightarrow{H} S^4, \quad [H] = 1 \in \mathbb{Z} \cong \pi_7(S^4).
\]

That M-brane charge should take values in degree-4 cohomotopy this way was first proposed in [Sa13, Sec. 2.5].

**Remark 2.1** (Origin of group actions on the 4-sphere as the cohomology theory for M-branes). We may generalize the above reasoning to the presence of conical singularities, and thereby motivate the group actions on the 4-sphere that we consider in Section 5 below.

(i) By [MedFig109] (see Prop. 4.15 below), the near horizon geometry of the \( \geq 1/4 \)-BPS black M2-brane is \( \text{AdS}_4 \times S^7/G_{ADE} \), where \( G_{ADE} \) acts along the twisted diagonal, via the identification

\[
\begin{align*}
S^7 & \cong S(H \oplus H), \\
S^7 & \cong S(H \oplus H),
\end{align*}
\]

where both copies of \( SU(2) \) act by their defining representation on \( \mathbb{H} \cong \mathbb{C}^2 \) (77).

(ii) Hence, in order for the quaternionic Hopf fibration (7) to also measure the charge of M2-branes at such singularities, we need an \( SU(2)_L \times SU(2)_R \)-action on \( S^4 \) which makes the quaternionic Hopf fibration \( H \) be an equivariant map (12) (see Remark 3.8 below on notation):

\[
\begin{align*}
SU(2)_L \times SU(2)_R & \xrightarrow{H} SU(2)_L \times SU(2)_R \\
S^7 & \xrightarrow{H} S^4.
\end{align*}
\]

By the explicit formula (80) for \( H \), this is the case precisely for the action

\[
SU(2)_L \times SU(2)_R \\
S^4 \cong S(R \oplus \mathbb{H}),
\]

where \( SU(2)_L \) acts on \( \mathbb{H} \) by quaternion multiplication from the left, while \( SU(2)_R \) acts by quaternion multiplication with the inverse from the right (77). These are the \( SU(2) \)-actions on \( S^4 \) which we consider in Def. 5.1 below.
This is consistent also with the charge carried by M5-branes at singularities: when the element acting
from the right is trivial, then the remaining quotient by finite subgroups of SU(2) acting from the left
provides precisely the near horizon geometry AdS$_7 \times S^4/(G_{ADE})_L$ of black M5-branes at singularities, see
Example 2.8.

Similarly, when the black M5-brane is situated at a Hořava-Witten Z$_2$-singularity (Example 2.8), then
its near horizon geometry is AdS$_7 \times S^4/(Z_2)_{\text{HW}}$, where the involution (Example 3.3) acts by reflection of
one of the coordinates

$$S^4 \simeq S((\mathbb{R}^4 \oplus \mathbb{R})_Z).$$

Hence, by the same reasoning as before, the correct coefficient object to measure M-brane charge at Hořava-
Witten singularities is again the 4-sphere, now equipped with this Z$_2$-action. This is what we consider in
Def. 5.1.

In conclusion, this says that the correct coefficient space for the cohomology theory measuring M-brane
charge is essentially identified with the 4-sphere in spacetime around a black M5-brane, as indicated in the
figures on p. 5. This way, analysis of the near horizon geometry of black M-branes supports the suggestion
that the correct generalized cohomology theory measuring M-brane charge is at least closely related to
equivariant cohomotopy in degree 4.

In order to substantiate that equivariant enhancement of fundamental brane cocycles is a plausible
candidate for the M-theoretic degrees of freedom that are “hidden” at spacetime singularities, and that
Theorem 6.1 below may reasonably be regarded as providing a cohomological black brane scan for branes at
singularities (in fact a unified fundamental-and-black brane scan), we now walk through selected discussions
in the literature, of black p-branes at singularities, and expand on how to match them to the equivariant
cocycle data found in Sections 4, 5, and 6, via this kind of translation.

The $\geq 1/4$-BPS branes. Here we compare the items in the classification of simple super singularities from
Theorem 4.3 to the literature.

Example 2.2 (The MO9). The item denoted “MO9” in Theorem 4.3 is of course readily identified with
the Z$_2$-fixed locus of Hořava-Witten theory [HoWi95, HoWi96, whence our notation “G$_{\text{HW}}$” for the
corresponding group action. The characteristic relation [HoWi95, equation (2.2)] is of course the content of
Lemma 4.10. It is, however, noteworthy that the nature of the Hořava-Witten fixed locus among the other
M-branes had been unclear, not the least because, due to its singular nature, it is not a BPS solution of
11-dimensional supergravity; see the beginning of [BeSc98], where the term “M9-brane” for this object was
first suggested. A clear identification of the role of the MO9 among the other branes, in its appearance as
the O8-plane in type I string theory, is in [GKST01, Sect. 3], see also Example 2.8.

Now, the point of [HoWi95, HoWi96] is to argue that the worldvolume of the MO9 is to be identified
with the spacetime that the heterotic string propagates in, and that, somehow, that heterotic string is also
to be identified with the boundary of the M2-brane ending on the MO9, see also Example 2.10. That story
evidently matches the data in the equivariant cocycle enhancement that appears labeled M2 $\dashv$ MO9 in
Table 3 of Theorem 6.1.

Example 2.3 (The M5). Similarly to Example 2.2, the computation in [Wit95c, Sec. 2.1], characterizing a
black M5-brane, is precisely that in Lemma 4.12 identifying the fixed locus of a 5-brane involution, in the
sense of Def. 4.4. The conclusion in [Wit95c, Sec. 3.] is that, for anomaly cancellation, some of these black
M5-branes need to sit at the singularity of an orbifold locally of the form

$$\mathbb{R}^{5,1} \times (\mathbb{R}^5 \!/ Z_2),$$

where Z$_2$ acts by reversing all the coordinates of $\mathbb{R}^5$ (also called an MO5, in analogy with Example 2.2).
This is precisely the action of the 5-brane involution of Lemma 4.12.
Notice that the M5 at such an $\mathbb{Z}_2$-singularity is not a solution of supergravity anymore (just as for the MO9 in Example 2.2), but must be something that M-theory needs to make sense of. While hence an ordinary black 5-brane does not/need not sit at the $\mathbb{Z}_2$-singularity, the analysis of flux quantization conditions in [Hor97] shows that if it meets a $\mathbb{Z}_2$-singularity, then it cannot do so just partially.

Also notice that the M5-branes at orientation-preserving $\mathbb{Z}_2$-singularities arise from a further intersection with an ADE-singularity, this the $\text{M5}_{\text{ADE}}$ in Example 2.7.

Example 2.4 (The MW). The M-wave (MW) is well-known as a supergravity $1/2$-BPS solution (due to [Hul84], see [Ph05] for decent review), but remains somewhat neglected in the literature on M-branes. Where it turns out to intersect with the M2-brane in [BPST10 Sec. 2.2.3], the authors find that “natural, if slightly unusual” (bottom of p. 13). It seems that there is no previous reference that suggests that the M-wave may sit at an $\mathbb{Z}_2$-singularity in just the same way as the MO9 (Example 2.2) and the single M5 do (Example 2.3), and as suggested by the classification in Prop. 4.7.

But the image of the spinor-to-vector pairing on the M-wave has the special property that it is just one of the two light rays (this is made fully explicit in [Ph05 p. 94]), which identifies its worldvolume structure with what is found in (46) in Lemma 4.10.

Example 2.5 (The M2). The article [MedFig+09] gives a complete classification of $\geq 1/4$-BPS black M2-brane solutions (5). The result of this is that these are all of the form

$$\text{AdS}_4 \times (S^7/G_{\text{ADE}}),$$

as in (5), where the quotient of the 7-sphere on the right is that induced by any one of the ADE-actions on $\mathbb{R}^8 \simeq \mathbb{R}^4 \oplus \mathbb{R}^4$ that are labeled “M2” in Theorem 4.3 under the identification $S^7 \simeq S(\mathbb{R}^8)$. Comparison with (5) shows that the actual singularity itself, if it were included in the spacetime, would be sitting at $r = 0$, hence at the origin of $\mathbb{R}^8$. That origin, of course, is precisely the fixed point set of the $G_{\text{ADE}}$-action (45) on $\mathbb{R}^8$. This situation

$$\mathbb{R}^{2,1} \times (\mathbb{R}_+ \cup \{0\}) \times S^7 / G_{\text{ADE}} \simeq \mathbb{R}^{2,1} \oplus \mathbb{R}^8 / G_{\text{ADE}},$$

is what is illustrated in the two items in Figures 1 and 2 that involve M2:

In fact, this identification is precisely how the classification in [MedFig+09] works: using results of [Wa89], the problem is first reduced to the case of spherical space forms $X_7 \simeq S^7 / G$. Now that $S^7 / G$ is $\geq 1/4$-BPS means equivalently that its space of Killing spinors is at least $1/4$ of its maximally possible size. But by a theorem of [Bar93], Killing spinors on $S^7 / G$ are equivalently $G$-constant spinors on the metric cone $C(S^7) \simeq \mathbb{R}^8$. These constant spinors, in turn, are precisely the spinorial fixed points that appear in Theorem 4.3.

Last not least, 3d superconformal field theories have famously been identified, which have the properties expected of the worldvolume field theories of M2-branes, see [BLMPT13]. These field theories have an ADE-classification, and inspection shows that their scalar fields are as expected if the the corresponding M2-branes
sit at an ADE-singularity in the way just discussed. (Of course this is the very motivation for the classification in [MedFig^+09].)

**Example 2.6 (The MK6).** The *Kaluza-Klein monopole* solution of plain 11-dimensional supergravity is different from the other black brane solutions, in that it does not feature a spacetime singularity. But it may be regarded as a circle fibration over the 10-dimensional type IIA super spacetime base, and as such it is singular, in that the circle fiber degenerates on a 6 + 1-dimensional locus. This is the 11-dimensional KK-monopole as a singular locus. Conversely, if that locus is removed from the spacetime manifold, then on the complement we have the total space of a non-singular fibration, in fact a principal $S^1$-bundle.

Generally, given any $S^1$-fibration $X_{11} \to X_{10}$, one may consider the canonical inclusion of a cyclic group into $S^1 \cong U(1)$, as a subgroup of roots of unity $\mathbb{Z}_n \hookrightarrow U(1)$ and hence the induced quotient bundle $X_{11}/\mathbb{Z}_n \to X_{10}$. Since $S^1/\mathbb{Z}_n \cong S^1$ is still a circle, just an “$n$-times smaller” circle, this is still a circle bundle over type IIA spacetime. Since the radius of the circle fiber of the 11d spacetime over $X_{10}$ is supposed to be the M-theoretic incarnation of the coupling parameter of the type IIA string on $X_{10}$, it is natural to regard such quotients, as $n$-varies. The limit where M-theory is supposed to asymptote to the perturbative type IIA superstring would then be the limit $n \to \infty$.

But now, if the circle fibration is actually degenerate, as it is for the Kaluza-Klein monopole, then the quotient spacetime $X_{11}/\mathbb{Z}_n$ is singular after all, with a $\mathbb{Z}_n$-singularity at the locus of the KK-monopole. One argues that from the point of view of the type IIA string theory this configuration is the black D6-brane [Tow95, p. 6-7], [Sen97, Sect. 2], [AtWi03, p. 17-18]. Accordingly, the KK-monopole in this singular incarnation ought to be an M-brane, the MK6.

We review the following more sophisticated (albeit still informal) argument for why the MK6-brane may occupy more general ADE-singularities, and that there must be “hidden M-theory degrees of freedom” at these singularities, not seen in the supergravity approximation; namely degrees of freedom that in the approximation of the type IIA string theory incarnate as nonabelian gauge fields on the D6-brane.

This argument goes back to [Sen97, Sect. 2], brief recollection may be found in [Wit02, Sec. 4.I], [IU12, Sec. 6.3.3]. We should amplify that, fascinating as the following picture is, it remains a conjectural story that is waiting to be substantiated by actual mathematics of M-theory:

Consider 11-dimensional spacetime that is locally the Cartesian product

$$\mathbb{R}^{6,1} \times \mathbb{C}^2/G_{ADE}$$

of 6+1-dimensional Minkowski spacetime with the orbifold quotient of the canonical action of a finite subgroup of SU(2) (Remark A.9). In terms of algebraic geometry, the underlying ordinary quotient $\mathbb{C}^2/G_{ADE}$ may naturally be regarded as a complex variety that is non-smooth – hence singular – at the origin. The specific singularities arising this way are known as *du Val singularities* [DuVal34].

Algebraic geometry knows a canonical process of smoothing out singular points in varieties, called *blowup of singularities*. Now the blowups specifically of du Val singularities have the following striking property (due to [DuVal34, I, p. 1-3 (453-455)] see [Re87] for a quick overview and [Slo80, Section 6] for a comprehensive account):

**Magic blowup property of du Val singularities.** The blowup of the du Val singularity in $\mathbb{C}^2/G_{ADE}$ is a union of spheres that touch (“kiss”) each other such that connecting the touching points by straight lines yields the Dynkin diagram given by the same ADE-label that also classifies the group $G_{ADE}$ according to the table in Remark A.9.

The following picture illustrates the the situation of such spheres touching according to an A-type Dynkin diagram, hence resolving the singular point of the quotient of $\mathbb{C}^2$ by the action of a cyclic group, via SU(2)
So far the mathematics of algebraic geometry. Now the suggestion is that one interprets this situation in terms of M-theoretic geometry: as shown, one may think of these spheres as being $S^1$-fibrations over this Dynkin diagram, with degenerate fibers over the vertices of the diagram. If we identify this with the M-theory circle fibration of 11-dimensional supergravity fibered over a 10d type IIA spacetime, then this is a multi KK-monopole-solution of 11d sugra, with KK-monopoles centered at vertices of the Dynkin diagram. From this perspective, one imagines that the original singularity may be understood as the result of taking two consecutive limits, namely:

**Limit 1:** first taking the type IIA-limit where the radius of the circle fibers is taken to zero;

**Limit 2:** and then taking the further limit where the vertices of the Dynkin diagram tend to coincide.

The string theoretic interpretation of the first limit is that the SuGra KK-monopoles becomes D6-branes in type IIA string theory, and hence the second limit yields a configuration of $n$-coincident D6-branes. By turning this around, the original du Val singularity must have been the M-theoretic incarnation of what in the approximation of string theory looks like coincident D-branes: this is the black MK6-brane.

If one, moreover, considers M2-brane instantons wrapping these spheres, then the first of these two limits gives the double dimensional reduction of the M2-brane to non-perturbative strings stretching between D6-branes, and in the second limit, where the D6-branes coincide, these D6-branes lose their tension energy and thus become massless perturbative strings. From perturbative string theory it is known that these are quanta of nonabelian gauge fields on the worldvolume of the D6-branes. Finally, if M-theory is supposed to be a refinement of string theory, a pre-image of these nonabelian gauge field degrees of freedom must have existed already on the black MK6-brane at the singularity. This is one incarnation of the mysterious M-theory degrees of freedom hidden at the ADE-singularity.

**Examples of intersecting M-branes.** Now we compare some of the examples of intersecting singularities from Prop. 4.19 to the literature.

**Example 2.7 (The $M_{5\text{ADE}}$).** According to [DZHTV15, Sect. 3], the configuration of an M5 placed inside an MK6 is supposed to have worldvolume theory the $D = 6$, $\mathcal{N} = (1,0)$ superconformal QFT with the corresponding ADE-classification of its gauge field content. This corresponds to the item labeled $M_{5\text{ADE}}$ in Prop. 4.19 as shown in Figure 1. Notice that this means that the M5-brane at an ADE-singularity necessarily sits inside a larger 6-brane, which it thereby “divides in half”; see also the discussion in Example 2.8.

With this in mind, we interpret the discussion in [MedFig09, Section 8.3], which aims at a classification of the near horizon geometries for black M5-brane solutions of 11d supergravity. We may translate the considerations there to those here by exactly the same logic as in Example 2.5. In that language, the result of [MedFig09, Section 8.3] is that the would-be M5 is necessarily inside a larger fixed locus, corresponding to a 6-brane:
We quote the mathematical result of [MedFig09, Section 8.3] in the proof of our Prop. 4.15, where the corresponding actions and fixed points appear labeled “MK6”.

Notice that there is not supposed to be a realization of the $D = 6, \mathcal{N} = (2,0)$ superconformal field theories in the ADE-series by M-branes at singularities (the A-series however is supposed to come from coincident M5-branes not placed at a singularity [Str96]). On the other hand, such realizations are supposed to exist in F-theory at ADE-singularities [HMV13]. But the starting point of our discussion here does also exists for F-theory ([FSS16b, Sect. 8]) and hence it should be possible to do an analogous analysis of equivariant cohomology for F-branes.

Example 2.8 (The $\frac{1}{2}$NS5). The intersection of a black M5 (Example 2.3) with an MO9 (Example 2.2) is not a solution to supergravity, but may be argued to be visible as an object of M-theory via the 6d superconformal worldvolume theory that it is supposed to carry [Ber98]. The resulting near horizon geometry involves the quotient $S^4 \sslash (\mathbb{Z}_2)_{\text{HW}}$ induced by the $\mathbb{Z}_2$-action that we consider in Def. 5.1.

More generally, one may consider the M5_{ADE} (Example 2.7) to intersect the MO9 [BrHa97, Section 2.4], [EGKRS00, EGKRS00], [GKST01, around Fig. 6.1, 6.2], [DZHTV15, Sections 6], [Fa17, p. 38 and around Fig. 3.9, 3.10]. This then accordingly involves the full $G_{\text{ADE}} \times \mathbb{Z}_2$-action that we consider in Def. 5.1, see specifically [DZHTV15, Section 7]. In [GKST01] this situation (regarded from the type I-perspective) is referred to as the “$\frac{1}{2}$NS5”-brane:

Example 2.9 (The M1). The intersection of the M2 (Example 2.5) with the M5 (Example 2.3) is also called the M-string [HI13, Sec. 2.3] [HIKLV15, HIKLV15]. In terms of boundary conditions for the expected worldvolume conformal field theory on the M2, this is argued to indeed exist in [BPST10, Sec. 2.2.1].

This clearly corresponds to the item M1 = M2 $\dashv$ 5 in Prop. 4.19.

Example 2.10 (The NS1_{H/E1}). That the intersection of the M2 (Example 2.5) with the MO9 (Example 2.2) should be the heterotic string, if the MO9 is orthogonal to the M-theory circle fiber, is the key claim of [HoWi95, HoWi96] (Hořava-Witten theory) (if it is longitudinal to it, then this intersection is called the
The actual black brane configurations exhibiting this have been considered in [LLO97, Kas00]. That the expected superconformal worldvolume theory on the M2-branes may have boundary conditions corresponding to an MO9 is argued in [BPST10, Section 2.2.2].

This clearly corresponds to the item NS1_H = M2 ⊣ MO9 in Prop. 4.19.

Notice that in the folklore the distinction, if any, between the fundamental heterotic string and its black brane incarnation remains ambiguous, not the least because, without actual M-theory in hand, the corresponding M2-brane is really known only in its supergravity approximation. But a look at the item denoted NS1_H = M2 ⊣ MO9 in Table 3

indicates that Theorem 6.1 serves to resolve the subtle distinctions and identifications involved in Hořava-Witten theory: the equivariant cocycle data (via Example 3.49) shown in (8) exhibits, on the right, the fundamental heterotic string cocycle \( \mu_{F1}^H \) (Example 3.40) on the worldvolume of the MO9. At the same time, on the bottom right, it relates the fundamental heterotic string to its own black brane incarnation, via the Green–Schwarz functional \( svol_{1+1} \) appearing on the superembedding of the string worldsheet into the MO9 worldvolume, according to Prop. 6.11. Finally, the left part of the diagram witnesses that this black string is indeed the boundary of the black M2-brane ending on the MO9, according to Prop. 4.19.

This concludes our comparison of selected items from Theorem 4.3 and Theorem 6.1 to existing classification of supergravity solutions and informal arguments from the string/M-theory literature. One could discuss more examples, but this should suffice to support the suggestion that (rationally) M-branes, both fundamental branes, black branes, as well as their various “bound states”, are classified by real equivariant cohomotopy of super-spacetimes.

Using this precise formulation, one may now go ahead and compile comprehensive classifications of real equivariant cohomotopy classes on super-spacetimes, explore dualities, and, eventually, search for the all important lift beyond the rational approximation. But since the present article is clearly long enough already, we relegate such investigations to elsewhere.

### 3 Equivariant super homotopy theory

Here we establish the context of homotopy theory within which the results in Section Sections 4, 5, and 6 are cast. First we briefly review ordinary equivariant homotopy theory in Section 3.1. Then, in Section 3.2, we set up the \textit{equivariant rational super homotopy theory} in which our main theorem 6.1 will take place.

Throughout, we take \( G \) to be a finite group (equipped with the discrete topology), such as for instance a cyclic group

\[ G = \mathbb{Z}_n := \mathbb{Z}/(n\mathbb{Z}) \]

or more generally a finite subgroup of SU(2) (see Remark A.9 below). The trivial group, i.e. the group whose only element is the neutral element, we denote by \( \{e\} \) or simply by 1. All of the following generalizes to the case that \( G \) is allowed to be a compact Lie group, such as the circle group \( U(1) \), if one considers fixed point loci for the \textit{closed} subgroups only. But for brevity we will not explicitly discuss this generalization here.
3.1 Ordinary equivariant homotopy theory

We recall enough of the background on *equivariant homotopy theory*, i.e. of the homotopy theory of topological spaces equipped with \( G \)-actions, in order to state and explain the relevance of *Elmendorf’s theorem* (Theorem 3.26 below). This is the basis for the generalization to equivariant super homotopy theory in Section 3.2. For a comprehensive introduction to equivariant homotopy theory see [Blu17], for further reading see [May96], [HHR09, appendix]. Some basic concepts of general homotopy theory are recalled in Section A.2.

**Homotopy theory of \( G \)-Spaces**

To fix notation, we begin by recalling some standard facts.

**Definition 3.1 (Group actions).** Let \( G \) be a topological group and \( X \) a topological space. Then a *continuous action* of \( G \) on \( X \) is a continuous function

\[
\rho: G \times X \to X
\]

such that

\[
\rho(1)x = x \quad \text{and} \quad \rho(g_1)\rho(g_1)x = \rho(g_1g_2)x
\]

where we write \( \rho(g, x) \) as \( \rho_g(x) \), as is conventional for group actions. When \( \rho \) is understood, we will write \( \rho(g)x \) as simply \( gx \).

**Remark 3.2 (Shorthand notation).** As is typical in physics, we will write:

\[
G_\rho := (G, \rho)
\]

for the pair of data consisting of a group with a chosen action. For instance, in Sections 4, 5, and 6 three different actions of the group \( \mathbb{Z}_2 \), play a role, and we will denote them \( G_{\text{ADE}}, G_{\text{HW}} \) and \( G_{\text{ADE,HW}} \), respectively.

**Example 3.3 (\( \mathbb{Z}_2 \)-actions are involutions).** An action (Def. 10) of the cyclic group of order two, \( \mathbb{Z}_2 = \{e, \sigma\} \), is equivalently an *involution* on a topological space, namely a continuous function

\[
X \xrightarrow{\rho(\sigma)} X
\]

such that \( \rho(\sigma)^2 = 1_X \).

**Definition 3.4 (Spaces associated with a \( G \)-action).** Let \( G \) be a group equipped with an action (Def. 3.1) on some topological space \( X \). This naturally induces the following structures (we now use the shorthand notation of Remark 3.2):

(i) The *orbit* of \( x \) is the subspace of \( X \) given by \( G(x) := \{gx : g \in G\} \).

(ii) The *isotropy group* of a point \( x \in X \) is the subgroup of \( G \) defined as \( G_x := \{g \in G : gx = x\} \).

Having fixed \( x \in X \), the natural map \( G \to X \) given by \( g \mapsto gx \) induces a homeomorphism \( G/G_x \cong G(x) \). Note also that the isotropy groups \( G_{gx} \) of any other element \( gx \) is related to \( G_x \) by conjugation with \( g \): \( G_{gx} = gG_x g^{-1} \).

(iii) The *fixed point space* of \( G \) acting on \( X \) is the subspace

\[
X^G := \{x \in X \mid gx = x \text{ for all } g \in G\}
\]

(iv) The *orbit space* \( X/G \) is the quotient topological space of \( X \) by the equivalence relation generated by setting \( x \sim gx \) for some \( g \in G \). Note that if \( G \) acts freely on \( X \) then the quotient map \( X \to X/G \) is a regular covering with \( G \) as a group of deck transformation.
Example 3.5 (Group actions on $\mathbb{R}^n$). Note that not every finite group action (Def. 3.1) on $\mathbb{R}^n$ needs to have fixed points (Def. 3.4). Indeed, in [CF59] first examples of $\mathbb{Z}_n$-actions on $\mathbb{R}^n$ without fixed points are given. Later, smooth fixed point free actions on $\mathbb{R}^n$ of $G = \mathbb{Z}_{pq}$, for two relatively prime integers $p, q \geq 2$ are given in [Br72, pp. 58-61]. This has the implication that one has to pick the appropriate action in order to achieve gauge enhancement of M-branes.

Definition 3.6 (Types of group actions). A group action (Def. 3.1) is called
(i) free if for any two points $x, y \in X$ there is at most one element $g \in G$ with $g(x) = zy$;
(ii) semi-free if it is free away from the fixed points (Def. 3.4).

Definition 3.7 (Topological $G$-spaces). (i) A topological $G$-space is a topological space $X$ equipped with a continuous $G$-action (Def. 3.1). For $(X_1, \rho_1)$ and $(X_2, \rho_2)$ two topological $G$-spaces, a $G$-equivariant map between them is a continuous function $X_1 \xrightarrow{f} X_2$ between the corresponding topological spaces which respects the $G$-action, in that
\[
f(\rho_1(g)x) = \rho_2(g)f(x) \quad \text{for all } x \in X_1 \text{ and } g \in G.
\] (12)
(ii) We write $G\text{Spaces}$ for the corresponding category of topological $G$-spaces. Moreover, for $X_1, X_2 \in G\text{Spaces}$, we write
\[
Maps(X_1, X_2)^G \subset Maps(X_1, X_2) \in \text{Spaces}
\] (13)
for the mapping space of $G$-equivariant continuous functions between them, equipped with the compact-open topology.

Remark 3.8. We will sometimes write a $G$-equivariant map as follows:
\[
\begin{array}{ccc}
\bigcirc & \bigcirc \\
X_1 & f & X_2
\end{array}
\] (14)
which is to be understood as saying that $f$ is a continuous function from $X_1$ to $X_2$ and $G$-equivariant according to (12).

Example 3.9 (Ordinary topological spaces as topological $G$-spaces). For $G = \{e\} = 1$ the trivial group, a topological $G$-space is just a topological space. Similarly, the $G$-equivariant homotopy theory described in the following reduces to classical homotopy theory in this case.

Example 3.10 ($G$-invariance as $G$-equivariance). If $X$ is a topological $G$-space (Def. 3.7), but $A$ is just a topological space (Def. A.15), regarded as a topological $G$-space with trivial $G$-action, via Example 3.9, then $G$-equivariant functions (12) from $X$ to $A$, which, following Remark 3.8, we may denote by
\[
\begin{array}{ccc}
\bigcirc & \bigcirc \\
X & f & A
\end{array}
\] (15)
are equivalently $G$-invariant functions, satisfying
\[f(gx) = f(x) .\]

Example 3.11 (Real spaces). For $G = \mathbb{Z}_2 = \{e, \sigma\}$ the cyclic group of order two, a topological $G$-space $X$ (Def. 3.7), hence a topological $\mathbb{Z}_2$-space is also called a real space ([Ati66, Section 1]). By Example 3.3, this is a topological space equipped with a topological involution. For instance, if $X$ is the underlying topological space of a complex algebraic variety, it becomes a $\mathbb{Z}_2$-space or real space via the involution induced by complex conjugation. In this sense, real structure on a topological space is a generalization of real structure on a complex vector space, making it a real vector space.
Example 3.12 (Basic kinds of $G$-spaces). Basic families of topological $G$-spaces (Def. 3.7) include the following:

- Any topological space $X$ becomes a $G$-space by equipping it with the trivial action $\rho(g,x) = x$. If we do not specify a $G$-action otherwise, then this trivial action will be understood.

- For $H \subset G$ a subgroup of $G$, the coset space $G/H$ inherits a $G$-action from the left multiplication of $G$ on itself. We will always understand these coset spaces to be $G$-spaces via this choice of $G$-action.

  - Observe that given any point $x \in X$ in a topological $G$-space $X$, then the orbit of $x$ under the $G$-action (Def. 3.4) looks like $G/H$, for $H \subset G$ the stabilizer subgroup which fixes $x$. Hence we may think of the cosets $G/H$ as the possible orbit spaces.

  - Observe that for the degenerate case when $H = G$, the coset $G/G$ is the point. We will find below that equivariant homotopy theory is like ordinary homotopy theory, but with the single point $\ast = G/G$ promoted to a systems of generalized points given by the orbit spaces $G/H$. This is formalized by the statement of Elmendorf’s theorem (Theorem 3.26 below).

- For $X_1$ and $X_2$ two $G$-spaces, their Cartesian product space $X_1 \times X_2$ becomes a $G$-space via the diagonal action $g(x_1,x_2) = (gx_1,gx_2)$.

Using the classes of basic examples from Example 3.12 as building blocks yields the following concept of $G$-cell complexes. The equivariant Whitehead theorem (Theorem 3.19 below) states that the homotopy category of these complexes yields the full equivariant homotopy theory.

Definition 3.13 ($G$-cell complexes (see [Blu17, Def. 1.2.1])).

(i) For $n \in \mathbb{N}$, and $H \subset G$ a subgroup, we say that the basic $n$-dimensional $G$-space cell at stage $H$ is the Cartesian product $D^n \times G/H$ of the topological unit $n$-ball $D^n$ equipped with the trivial $G$-action and a coset space equipped with its canonical $G$-action, as in Example 3.12.

(ii) A $G$-CW-complex $X$ is the $G$-space defined inductively, starting with $X_0$ a disjoint union of 0-dimensional $G$-space cells, and then given $X_{n-1}$, gluing $n$-dimensional $G$-space cells via $G$-equivariant maps to obtain $X_n$. The colimit of this sequence is $X$.

(iii) We write

$$
\text{GCWComplexes} \xrightarrow{I} \text{GSpaces}
$$

for the full subcategory of topological $G$-spaces (Def. 3.7) on the $G$-CW-complexes.

Next we consider the actual homotopy theory of topological $G$-spaces, and pass to the corresponding homotopy categories of these two models for $G$-spaces. These homotopy categories will turn out to be equivalent to each other, thus providing us with two different but equivalent perspectives, each with its own advantages, on $G$-equivariant homotopy theory.

Definition 3.14 (Equivariant homotopy). Given two topological $G$-spaces $X_1$, $X_2$ (Def. 3.7) and given two $G$-equivariant maps $f_0, f_1 : X_1 \to X_2$ between them (see 12), we say that a $G$-equivariant homotopy from $f_0$ to $f_1$ is a $G$-equivariant map of the form

$$
\eta : X_1 \times [0,1] \to X_2,
$$

where the interval $[0,1]$ is equipped with the trivial $G$ action, and $\eta$ satisfies:

$$
\eta(x,0) = f_0(x), \quad \eta(x,1) = f_1(x).
$$

\[11\] The cells in a cell complex are the spatial analogs of algebra generators in an algebra.
In other words, this is a 1-parameter family of $G$-equivariant maps that continuously interpolates between $f_0$ and $f_1$. We denote this homotopy by

\[
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{f_0}
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{f_0}
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{X_1 \xrightarrow{\eta} X_2}.
\]

**Definition 3.15** (Equivariant homotopy equivalences). A $G$-equivariant homotopy equivalence is a $G$-equivariant map $f: X_1 \to X_2$ which has an inverse up to $G$-equivariant homotopy (Def. 3.14). This means that there exist a $G$-equivariant function $\tilde{f}: X_2 \to X_1$ and $G$-equivariant homotopies

\[
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{id}
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{id}
\begin{array}{c}
X_1 \\
\downarrow \eta \\
X_1 \\
\downarrow \eta \\
X_2
\end{array}
\xrightarrow{X_1 \xrightarrow{\eta} X_2}.
\]

In ordinary homotopy theory, homotopy equivalence between spaces turns out to be too strong. Instead, we pass to weak homotopy equivalence, given by any map that induces isomorphisms between homotopy groups. This weaker notion also has an analog in the equivariant setting.

**Definition 3.16** (Weak equivariant homotopy equivalence). Let $X_1$ and $X_2$ be two topological $G$-spaces (Def. 3.7). Then a $G$-equivariant function between them (12)

\[f: X_1 \to X_2\]

is called a weak $G$-equivariant homotopy equivalence if for every subgroup $H \subset G$ the induced map on $H$-fixed point spaces (Def. 3.22)

\[f^H: X^H_1 \to X^H_2\]

is an ordinary weak homotopy equivalence (Def. A.16).

**Remark 3.17.** As in the non-equivariant setting, every equivariant homotopy equivalence (Def. 3.15) is also a weak equivariant homotopy equivalence (Def. 3.16), but not conversely.

**Definition 3.18** (Homotopy theory of topological $G$-spaces). We equip the categories of topological $G$-spaces from Def. 3.7 and Def. 3.13 with weak equivalences (Def. A.13) as follows:

1. On the category $G$CWComplexes (Def. 3.13) we take the weak equivalences to be the equivariant homotopy equivalences from Def. 3.15.
2. On the category $G$Spaces (Def. 3.7) we take the weak equivalences to be the weak equivariant homotopy equivalences from Def. 3.16.

Given any category with weak equivalences like the examples above, we can form its homotopy category by inverting the weak equivalences. The resulting homotopy categories (Def. A.13) are as follows:

\[
\begin{align*}
&\Ho(GCWComplexes) := \Ho(GCWComplexes[\{\text{equivariant homotopy equivalences}\}^{-1}]) \\
&\Ho(GSpaces) := \Ho(GSpaces[\{\text{weak equivariant homotopy equivalences}\}^{-1}]).
\end{align*}
\]

The following fact is the first indication that equivariant homotopy theory elevates the collection of fixed point loci to a special role in the theory.

**Proposition 3.19** (Equivariant Whitehead theorem ([Wan80 Thm 3.4], see [Blu17 Cor. 1.2.14])). Under passage to the homotopy categories of Def. 3.18, the inclusion $I$ in (16) from Def. 3.15 induces an equivalence of categories:

\[
\begin{array}{c}
\Ho(GCWComplexes)
\end{array}
\xrightarrow{I}
\begin{array}{c}
\Ho(GSpaces)
\end{array}.
\]

Therefore, we now turn our full attention to these systems of fixed point loci.
Systems of fixed point loci

For any $G$-space $X$, an orbit in $X$ is a $G$-space of the form $G/H$, where $H$ is the stabilizer of a point in the given orbit. This means we can form the collection of all possible orbits for all possible $G$-spaces: they are given by the coset spaces $G/H$. We thus call these coset spaces orbit spaces, as in Def. 3.12.

Definition 3.20 (The orbit category, see [Blu17, Def. 1.3.1]). We write

$$\text{Orb}_G \subseteq \text{GSpaces}$$

for the full subcategory of topological $G$-spaces (Def. 3.7) which are orbit spaces (Def. 3.12), called the orbit category of $G$. That is, the objects in this category are the coset spaces $G/H$, one for each subgroup $H \subset G$, and the morphisms are the continuous $G$-equivariant functions (12) between the coset spaces $G/H_1 \rightarrow G/H_2$.

Example 3.21 (Orbit category of $\mathbb{Z}_2$). Consider the orbit category (Def. 3.20) of the cyclic group of order two: $\mathbb{Z}_2 = \{ e, \sigma \}$ with a single non-trivial element $\sigma$, squaring to the neutral element $\sigma \cdot \sigma = e$. This has precisely two subgroups, namely itself and the trivial group $1 = \{ e \}$. Hence its orbit spaces are $\mathbb{Z}_2/\mathbb{Z}_2 = 1$ and $\mathbb{Z}_2/1 = \mathbb{Z}_2$. The non-trivial morphisms in the orbit category are depicted succinctly as follows:

$$\text{Orb}_{\mathbb{Z}_2} = \left\{ \begin{array}{c} \sigma \\ \mathbb{Z}_2/1 \\ \mathbb{Z}_2/\mathbb{Z}_2 \end{array} \right\}$$

Example 3.22 (Systems of fixed point spaces). If $X$ is a topological $G$-space (Def. 3.7), and $H \subset G$ a subgroup, then a $G$-equivariant map

$$G/H \xrightarrow{f} X$$

from the orbit space $G/H$ (Def. 3.12) must, by $G$-equivariance (12), send the equivalence class of the neutral element $e \in G$ to an $H$-fixed point of $X$, since the action of $H \subset G$ on $G/H$ is trivial. Moreover, still by equivariance, the choice of the image of the neutral element uniquely fixes the value of $f$ on all other points of $G/H$. This means that the equivariant mapping space (13) out of $G/H$ into $X$ is equivalently the subspace of $H$-fixed points (Def. 3.4)

$$X^H \simeq \text{Maps}(G/H, X)^G.$$  \hspace{1cm} (21)

Accordingly, for

$$G/H_1 \xrightarrow{f} G/H_2$$  \hspace{1cm} (22)

a $G$-equivariant map between two orbit spaces, precomposition with $f$ yields a continuous function between mapping spaces, going in the opposite direction:

$$\text{Maps}(G/H_2, X)^G \xrightarrow{(-) \circ f} \text{Maps}(G/H_1, X)^G.$$  \hspace{1cm} (23)

Under the equivalence with fixed-point spaces, this becomes a map:

$$X^{H_2} \xrightarrow{X^f} X^{H_1}.$$  \hspace{1cm} (23)

We can use equivariance to describe this map very explicitly. As noted above, $f$ is determined by where it sends the class $[e] \in G/H_1$. Let us call this value $[gf] \in G/H_2$, that is $f[1] = [gf]$, for some choice of representative $gf \in G$. Then $X^f(x) = gf \cdot x$ for any $H_2$-fixed point $x \in X^{H_2}$. The reader can check that this is well-defined and lands in the space of $H_1$-fixed points, $X^{H_1}$.
Moreover, this construction respects composition and identities:

\[ X^{f \circ g} = X^g X^f, \quad X^{\text{id}} = \text{id}. \]

We summarize this by saying that the system of \( H \)-fixed point spaces \( X^H \) of \( X \) as \( H \subset G \) varies is a presheaf of topological spaces on the orbit category \( \text{Orb}_G \) (Def. 3.20). This is denoted:

\[
\begin{array}{ccc}
\text{Orb}^\text{op}_G & \xrightarrow{X(-)} & \text{Spaces} \\
G/H_1 & \xrightarrow{f_1} & X^{H_1} \\
G/H_2 & \xrightarrow{f_2} & X^{H_2} \\
G/H_3 & \xrightarrow{f_{2 \circ f_1}} & X^{H_3}
\end{array}
\]

It will be useful to isolate the structure of systems of fixed point spaces, as in Example 3.22, as a concept in itself:

**Definition 3.23** (Systems of topological spaces indexed over the orbit category).

(i) A system of topological space indexed by the orbit category \( \text{Orb}_G \) (Def. 3.20), also called a presheaf of topological spaces on the orbit category, is an assignment of a topological space \( X^H \in \text{Spaces} \) to each subgroup \( H \subset G \) and of a continuous function \( X^f: X^H_1 \rightarrow X^H_2 \) to each \( G \)-equivariant map \( f: G/H_1 \rightarrow G/H_2 \) such that this assignment respects composition identities:

\[ X^{f \circ g} = X^g X^f, \quad X^{\text{id}} = \text{id}. \]

This is denoted:

\[
\begin{array}{ccc}
\text{Orb}^\text{op}_G & \xrightarrow{X} & \text{Spaces} \\
G/H_1 & \xrightarrow{f_1} & X^{H_1} \\
G/H_2 & \xrightarrow{f_2} & X^{H_2} \\
G/H_3 & \xrightarrow{f_{2 \circ f_1}} & X^{H_3}
\end{array}
\]

(ii) Given two such system \( X_1 \) and \( X_2 \), then a homomorphism between them, denoted

\[ F: X_1 \rightarrow X_2 \]

is an assignment of continuous functions

\[ F^H: X^H_1 \rightarrow X^H_2 \]

for each subgroup \( H \subset G \), such that this respects all the equivariant functions \( G/H_1 \overset{f}{\rightarrow} G/H_2 \) between orbit spaces, meaning that \( X^f_2 \circ F^H = F^H_1 \circ X^f_1 \), which we can summarize by saying the following square commutes for all \( f \):

\[
\begin{array}{ccc}
X^{H_1}_1 & \xrightarrow{F^{H_1}} & X^{H_1}_2 \\
X^f_1 & \xrightarrow{X^f_2} & X^f_2 \\
X^{H_2}_1 & \xrightarrow{F^{H_2}} & X^{H_2}_2.
\end{array}
\]
We write $\text{PSh}(\text{Orb}_G, \text{Spaces})$ for the category of systems of topological spaces indexed by the orbit category, with homomorphisms between them.

**Example 3.24.** The construction that associates a topological $G$-space $X$ (Def. 3.7) to its system of fixed-point spaces $X(-)$, according to Example 3.22, gives a functor

$$
\begin{array}{ccc}
G\text{Spaces} & \xrightarrow{Y} & \text{PSh}(\text{Orb}_G, \text{Spaces}) \\
X & \rightarrow & X(-)
\end{array}
$$

(26)

to the category of systems of topological spaces indexed over the orbit category (Def. 3.23).

This gives us a machine for turning $G$-spaces into systems of spaces indexed by the orbit category. It turns out that systems of spaces actually have the same homotopy theory as $G$-spaces, giving us a third model of equivariant homotopy theory. The key idea here is that the following weak equivalences are, on each orbit space, the same as the ordinary weak equivalences of classical homotopy theory:

**Definition 3.25 (Homotopy theory of systems of spaces over $\text{Orb}_G$).**

(i) We call a morphism $F(-) : X(-) \rightarrow Y(-)$ (24) in the category $\text{PSh}(\text{Orb}_G, \text{Spaces})$ from Def. 3.23 a weak equivalence if for each subgroup $H \subset G$ its component $F^H$ (25) is a weak homotopy equivalence of spaces (Def. A.16).

(ii) We denote the resulting homotopy category (Def. A.14) by

$$
\text{Ho} (\text{GFixedPointSystems}) := \text{Ho} \left( \text{PSh}(\text{Orb}_G, \text{Spaces}) \left[ \{ \text{subgroup-wise weak homotopy equivalences} \}^{-1} \right] \right).
$$

The following proposition, known as Elmendorf’s Theorem, says that the homotopy theory of $G$-spaces and of systems of spaces over $\text{Orb}_G$ are the same. In the next section, we will use Elmendorf’s Theorem to generalize equivariant homotopy theory to situations that do not admit “point-set models”, such as the 11d super spacetimes on which the M2/M5-brane cocycle is defined:

**Proposition 3.26 (Elmendorf’s Theorem ([El83], see [Blu17, Thm. 1.3.6 and 1.3.8])).** Under passage to the homotopy categories of Def. A.14, the functor $Y$ (26) from Def. 3.24 constitutes an equivalence of categories:

$$
\text{Ho} (\text{GSpaces}) \overset{\sim}{\longrightarrow}_{\text{Elmendorf}} \text{Ho} (\text{GFixedPointSystems})
$$

(27)

between the homotopy theory of $G$-spaces (Def. 3.18) and that of systems of spaces over $\text{Orb}_G$ (Def. 3.25).

In summary, we have the following system of homotopy categories

$$
\begin{array}{ccc}
\text{Ho} (\text{GCWComplexes}) & \overset{\sim}{\longrightarrow}_{\text{Equivalent Whitehead}} & \text{Ho} (\text{GSpaces}) & \overset{\sim}{\longrightarrow}_{\text{Elmendorf}} & \text{Ho} (\text{GFixedPointSystems}) \\
\text{Ho} (\text{CWComplexes}) & \overset{\sim}{\longrightarrow}_{\text{Whitehead}} & \text{Ho} (\text{Spaces}) & \overset{=}{\longrightarrow} & \text{Ho} (\{e\}\text{FixedPointSystems})
\end{array}
$$

Since all the homotopy categories in the top row and those in the bottom row are equivalent to each other, we use them interchangeably. So, we will often write $\text{Ho} (\text{GSpaces})$ and $\text{Ho} (\text{Spaces})$ for the top row and bottom row, respectively.

**Example 3.27 (Homomorphisms of systems of fixed points up to homotopy).** Consider the case that $G = \mathbb{Z}_2$ is the cyclic group of order 2, so that the orbit category is as in Example 3.21. Consider a topological $G$-space
A (Def. 3.7) with precisely one fixed point under the non-trivial element in \( \mathbb{Z}_2 \), so that its system of fixed point spaces according to Example 3.22 is

\[
A(-) : \quad \begin{array}{c}
\sigma \\
\downarrow \\
\mathbb{Z}_2/1 \\
\downarrow \\
\mathbb{Z}_2/\mathbb{Z}_2 \\
\end{array} \quad \quad \quad \quad \begin{array}{c}
\rho(\sigma) \\
\downarrow \\
A \\
\downarrow \\
a \\
\end{array} 
\]

Now let \( X \) be another \( G \)-space. Then a homomorphism \( X(-) \to A(-) \) of systems of fixed point spaces, according to Def. 3.23, is a pair of continuous functions \( X^1 \to A^1 \) and \( X^{\mathbb{Z}_2} \to A^{\mathbb{Z}_2} \) such that following square commutes:

\[
\begin{array}{ccc}
\mathbb{Z}_2/1 & \xrightarrow{\sigma} & X(-) \\
\downarrow & & \downarrow \\
\mathbb{Z}_2/\mathbb{Z}_2 & \xrightarrow{\rho(\sigma)} & A(-) \\
\end{array} \quad \quad \quad \quad \begin{array}{ccc}
\mathbb{Z}_2/1 & \xrightarrow{\sigma} & A \\
\downarrow & & \downarrow \\
\mathbb{Z}_2/\mathbb{Z}_2 & \xrightarrow{\rho(\sigma)} & A \\
\end{array}
\]

But as we pass to the homotopy category \( \text{Ho}(\text{PSh}((\text{Orb}_{\mathbb{Z}_2}), \text{Spaces})) \) from Def. 3.18, the system \( A(-) \) becomes equivalent to “more flexible” systems. In particular, according to Example A.17 there is a weak equivalence to the system which assigns to \( \mathbb{Z}_2/\mathbb{Z}_2 \) not the point, but the based path space of \( A \):

\[
\begin{array}{ccc}
\mathbb{Z}_2/1 & \xrightarrow{\sigma} & A \\
\downarrow & & \downarrow \\
\mathbb{Z}_2/\mathbb{Z}_2 & \xrightarrow{\rho(\sigma)} & A \\
\end{array} \quad \quad \quad \quad \begin{array}{ccc}
\mathbb{Z}_2/1 & \xrightarrow{\sigma} & A \\
\downarrow & & \downarrow \\
\mathbb{Z}_2/\mathbb{Z}_2 & \xrightarrow{\rho(\sigma)} & A \\
\end{array}
\]

Still by Example A.17, this means that in the homotopy category the commutative squares involved in the definition of the map (28) may be filled by a homotopy

\[
\begin{array}{ccc}
X & \xrightarrow{\alpha} & A \\
\downarrow & & \downarrow \\
X^{\mathbb{Z}_2} & \xrightarrow{\alpha} & A \\
\end{array} \quad \quad \quad \quad \begin{array}{ccc}
X & \xrightarrow{\alpha} & A \\
\downarrow & & \downarrow \\
X^{\mathbb{Z}_2} & \xrightarrow{\alpha} & A \\
\end{array}
\]

With equivariant homotopy theory in hand, our concern below in Sections 4, 5, and 6 will be to find equivariant enhancements of given cocycles in non-equivariant cohomology (see Example 3.49 below).

**Definition 3.28** (Enhancement of cohomology to equivariant cohomology). For \( X, A \) topological spaces (Def. A.15), let

\[
[c] = [X \xrightarrow{c} A] \in \text{Ho}(\text{Spaces})
\]

be the homotopy class of a map, hence the cohomology class of a cocycle on \( X \) with coefficients in \( A \). We will say that an enhancement of this to the cohomology class of a \( G \)-equivariant cocycle is a lift of this map through the forgetful functor

\[
\begin{array}{ccc}
\text{Ho}(\text{GSpaces}) & \xrightarrow{\text{ev}_1} & \text{Ho}(\text{Spaces}) \\
\downarrow & & \downarrow \\
\ast & \xrightarrow{[\cdot]} & \text{Ho}(\text{Spaces}) \\
\end{array}
\]

12 In the language of model category theory (see e.g. [Sch17b, Sec. 2]), the system involving the based path space is a fibrant resolution of the original system \( A(-) \) in the projective model category structure on functors (see e.g. [Sch17b Thm. 3.26]).
The following phenomenon will be of key importance in Sections 4, 5, 6. It explains how equivariant enhancement yields what physicists would call “extra degrees of freedom”:

**Remark 3.29** (Equivariant enhancement is extra structure). Note that an equivariant enhancement as in Def. 3.28 may not exist, and if it does, it involves a choice. This is because it may happen that there is a plain homotopy between \(G\)-equivariant maps but not a \(G\)-equivariant homotopy, so that the two maps represent the same homotopy class in \(\text{Ho}(\text{Spaces})\), but two different classes in \(\text{Ho}(G\text{Spaces})\):

\[
\begin{array}{c}
\mathcal{X} \\
\downarrow \quad \downarrow
\end{array}
\begin{array}{c}
A \\
\downarrow \\
\mathcal{X}
\end{array}
\quad [c_1] \neq [c_2] \in \text{Ho}(G\text{Spaces})
\]

\[
\begin{array}{c}
\mathcal{X} \\
\downarrow \quad \downarrow
\end{array}
\begin{array}{c}
A \\
\downarrow \\
\mathcal{X}
\end{array}
\quad [c_1] = [c_2] \in \text{Ho}(\text{Spaces})
\]

We spell out what this extra structure of equivariant enhancement means for general super-cocycles in Example 3.49. Our main Theorem 6.1 determines the ADE-equivariant enhancements of the cocycle of the fundamental M2/M5-brane.

### 3.2 Equivariant rational super homotopy theory

In this section we set the scene for the discussion in Sections 4, 5, and 6 by establishing the homotopy theory in which the equivariant gauge enhancement of the M2/M5-cocycle (Theorem 6.1 below) takes place, namely *equivariant rational super homotopy theory* (Def. 3.46 below).

Here *rational super homotopy theory* (Def. 3.30 below), is the evident generalization of plain rational homotopy theory (recalled as Def. A.18 below) regarded via Sullivan’s equivalence (recalled as Prop. A.20 below). This equivalence identifies the rational homotopy theory of sufficiently well-behaved spaces with that of sufficiently well-behaved differential-graded commutative algebras (see Def. A.19). Rational super homotopy theory (Def. 3.30 below) results from generalizing the latter to differential-graded *super*-algebras. In the supergravity literature, the cofibrant objects among these are known as “FDAs”, following [vN82, CDF91].

We had studied the rational super homotopy theory of super \(p\)-branes in [FSS16a, FSS15b, FSS13], for expository review see [Sch16]. From this discussion we here need that the M2/M5-brane WZW-term is a cocycle in non-equivariant degree four rational super cohomotopy, which we recall as Prop. 3.43 below.

Then we use the perspective provided by Elmendorf’s theorem (Prop. 3.26) to introduce the equivariant refinement of rational super homotopy theory (Def. 3.44 and Def. 3.46 below). We point out how super Lie algebras with \(G\)-action provide examples (Example 3.48 below) and we highlight which data is involved in a \(G\)-equivariant enhancement of a given super-cocycle (Example 3.49 below). These are key ingredients in the proof of our main theorem 6.1 below.

**Definition 3.30** (Rational super homotopy theory).

(i) We write \(\text{dgcSuperAlg}\) for the category whose objects are differential graded-commutative super-\(\mathbb{R}\)-algebras, whose morphisms are homomorphisms \(\phi : A_1 \to A_2\). This means, equivalently, that an object \(A \in \text{dgcSuperAlg}\) is a \(\mathbb{Z} \times \mathbb{Z}_2\)-graded differential algebra, with \(\mathbb{Z}\) the “cohomological grading” and with \(\mathbb{Z}_2 = \{\text{even, odd}\}\) the *super-grading*, hence where elements \(a_1, a_2 \in A\) of homogeneous bi-degree \((n_i, \sigma_i)\) satisfy (as in [CDF91 II.2.106-109], [DF99 Sec. 6]) the sign rule

\[
a_1a_2 = (-1)^{n_1\sigma_2}(-1)^{\sigma_1\sigma_2}a_2a_1,
\]

and such that the differential is of bidegree \((1, \text{even})\).
We take the weak equivalences (Def. A.13) in $\text{dgcSuperAlg}$ to be the quasi-isomorphisms (as in Def. A.19). Mimicking the “bosonic” Sullivan equivalence (Prop. A.20), the resulting homotopy category (Def. A.14) restricted to the connected and finite-type dgc-superalgebras (as in Def. A.19) we denote by

$$\text{Ho}(\text{SuperSpaces}_{\mathbb{R},cn,nil,fin}) := \text{Ho}(\text{dgcSuperAlg}_{\mathbb{R},cn,fin}^{\text{op}} \left[ \{\text{quasi-isomorphisms}\}^{-1}\right]) .$$

As in plain rational homotopy theory (see (87)) we may drop the connectedness condition by considering the category of indexed tuples of dgc-superalgebras on the right:

$$\text{Ho}(\text{SuperSpaces}_{\mathbb{R},nil,fin}) := \int_{S \in \text{Set}} \text{Ho}(\text{dgcSuperAlg}_{\mathbb{R},cn,fin}^{\text{op}} \left[ \{\text{quasi-isomorphisms}\}^{-1}\right])^S .$$

**Example 3.31** (Rational homotopy types as rational superspaces). Every ordinary dgc-algebra (Def. A.19) becomes a dgc-superalgebra (Def. 3.30) by regarding each element in even super-degree. Hence we have a full inclusion of rational homotopy theory (via Prop. A.20) into rational super homotopy theory

$$\text{Ho}(\text{Spaces}_{\mathbb{R},nil,fin}) \hookrightarrow \text{Ho}(\text{SuperSpaces}_{\mathbb{R},nil,fin}) .$$

**Remark 3.32.** One may generalize super-geometric homotopy theory beyond the rational, nilpotent and finite-type situation considered in Def. 3.30 (see dcct). For brevity and focus here we will not further discuss this, except that, to ease notation in the following, we remark that this yields a full embedding

$$\text{Ho}(\text{SuperSpaces}_{\mathbb{R},nil,fin}) \hookrightarrow \text{Ho}(\text{SuperSpaces}_{\mathbb{R}})$$

into a less restrained homotopy category, so that we may safely suppress the subscripts when discussing morphisms in the homotopy category (hence cocycles!, see Def. A.24) between given nilpotent finite-type superspaces.

**Example 3.33** (Rational cohomotopy of superspaces). The minimal dgc-algebra model for the rational 4-sphere (Example A.21) may be regarded as a dgc-superalgebra (Def. 3.30) by regarding each element in even super-degree. Hence we have a full inclusion of rational homotopy theory (via Prop. A.20) into rational super homotopy theory

$$S^4 \in \text{Ho}(\text{SuperSpaces}_{\mathbb{R},nil,fin}) .$$

This means (via Example A.25) that for $X$ any super space the rational degree four cohomotopy of $X$ is the set of morphisms

$$X \rightarrow S^4 \in \text{Ho}(\text{SuperSpaces}_{\mathbb{R}}) .$$

(On the right we are now using notation as in Remark 3.32)

**Example 3.34** (Super Lie algebras as superspaces). Let

$$g \simeq_{\mathbb{R}} g_{\text{even}} \oplus g_{\text{odd}}$$

be a finite-dimensional super Lie algebra. Then its Chevalley-Eilenberg algebra $\text{CE}(g) \in \text{dgcSuperAlgebra}$ is a dgc-superalgebra (Def. 3.30) and hence defines a rational superspace, which we will denote by the same symbol:

$$g \in \text{Ho}(\text{SuperSpaces}_{\mathbb{R}}) . \quad (31)$$

(If $g \simeq_{\mathbb{R}} g_{\text{even}}$ happens to be an ordinary Lie algebra (i.e. concentrated in even degree), then $\text{CE}(g)$ is an ordinary dgc-algebra and hence in this case (31) is in the inclusion of ordinary rational spaces from Example 3.31.) This construction extends to a functor from the category of finite-dimensional super Lie algebras to the homotopy category of rational super spaces:

$$\text{SuperLieAlg}_{\mathbb{R}} \rightarrow \text{Ho}(\text{SuperSpaces}_{\mathbb{R}}) . \quad (32)$$
Remark 3.35. Beware that, if, in Example 3.34 $g = (\mathbb{R}^n_{\text{even}}, [-,-] = 0)$ is the abelian (hence in particular nilpotent) Lie algebra on $n$-generators, then the rational space corresponding to its Chevalley-Eilenberg algebra under the Sullivan equivalence (Prop. A.20) is not the Cartesian space $\mathbb{R}^n$ (which instead is equivalent to the point in $\text{Ho}(\text{Spaces}_\mathbb{Q})$) but the $n$-torus $\mathbb{T}^n = \mathbb{R}^n/\mathbb{Z}^n$. This highlights that in (31) the Lie bracket structure is important. Nevertheless, we will often leave this notionally implicit, such as in Def. 3.36.

Definition 3.36 (Spin-invariant Super Minkowski spacetime (e.g. [FSS13, p. 10][HS17])).

(i) For $p \in \mathbb{N}$, let $N$ be a real representation of the group $\text{Spin}(p, 1)$ (Def. A.1) which is of real dimension $N \in \mathbb{N}$. This gives rise to the following DGC-superalgebra (Def. 3.30)

$$\text{CE}(\mathbb{R}^{p,1}|N/\text{Spin}(p,1)) := \left( \mathbb{R}\left[ (c^a)^p_{a=0} , (\psi^\alpha)^N_{\alpha=1} \right]/\left( \begin{array}{c} de^a = \bar{\psi} \Gamma^a \psi \\ d\psi^\alpha = 0 \end{array} \right) \right)^{\text{Spin}(p,1)} \in \text{dgcSuperAlg}.$$ \hfill (33)

Here the expression $\bar{\psi} \Gamma^a \psi$ on the right is obtained from the spinor-to-vector pairing (71), and the superscript $(-)^{\text{Spin}(p,1)}$ means that we consider the sub dgc-algebra of $\text{Spin}(p,1)$-invariant elements inside the dgc-algebra that is defined in the parenthesis.

(ii) Accordingly this defines (still by Def. 3.30) superspaces

$$\mathbb{R}^{p,1}|N/\text{Spin}(p,1) \in \text{Ho}(\text{SuperSpaces}_\mathbb{R})$$ \hfill (34)

which are the incarnation of super Minkowski spacetimes, in rational super homotopy theory, such that all maps out of them are forced to be $\text{Spin}(p,1)$-invariant. Since this is the only case we are ever concerned with, we will, right away, suppress the notation for Spin-invariance, and will just write

$$\mathbb{R}^{p,1}|N$$ \hfill (35)

for the superspaces in (34) from now on. Beware that this is deliberate abuse of notation, since the symbol (35) more properly refers to the superspace that corresponds to the full dgc-algebra inside the parenthesis in (33).

These super Minkowski spacetimes are a special case of Example 3.34 in that $\text{CE}(\mathbb{R}^{p,1}|N)$ is the Chevalley-Eilenberg algebra of the super-translation part of the $D = p + 1, N$-supersymmetry super Lie algebra. By Remark 3.35 this means that, when regarding super-Minkowski spacetime as an object in $\text{Ho}(\text{SuperSpaces}_\mathbb{R})$, it is crucial that we do take the super Lie bracket into account, and that we could make this more explicit by instead of (34) writing

$$\mathbb{T}^{p,1}|N \in \text{Ho}(\text{SuperSpaces}_\mathbb{R}).$$

Example 3.37 (Examples of super Minkowski spacetimes). Consider the general construction of Def. 3.36 for the real spin representations listed in Example A.4. This yields, among others, the following super Minkowski spacetimes (with $D := d + 1$ the total spacetime dimension and $N$ the “number of supersymmetries”, according to Remark A.5):

\[\text{If there are different real representations of the same real dimension we will distinguish them by extra decoration of their dimension in boldface, for instance N and N.}\]
The following Def. 3.38 reflects standard physics terminology for dimensionality of fermionic subspaces in super spacetimes. This will play a key role in the classification of real ADE-singularities in Section 4.

**Definition 3.38 (BPS super subspaces).** Let \( \mathbb{R}^{p,1|N} \) be a super-Minkowski spacetime (Def. 3.36). Then consider a sub-superspace, which is itself a super-Minkowski spacetime of the same bosonic dimension but with real Spin representation \( N/k \) of dimension some fraction \( \frac{1}{k}N \).

We call this a \( 1/k \) BPS super subspace.

Even though super Minkowski spacetimes (Def. 3.36) are a fairly mild variant of plain Minkowski spacetime, in contrast to the latter they have interesting ordinary cohomology, in fact exceptional cohomology: A finite number of invariant cocycles appear for special combinations of dimension \( D \), number of supersymmetries \( N \) and cocycle degree \( p+2 \). Since these exceptional cocycles witness fundamental branes propagating on these super Minkowski spacetimes, this classification was known as the brane scan, and has come to be known as the “old brane scan” (e.g. [DuLu92 Sect. 2], [Duff08 Sect. 3.1]), since, interestingly, it misses some branes (we discuss this in detail in Section 2.1 below):

**Proposition 3.39 (Old Brane Scan ([AETW87, AzTo89], see [FSS13])).** Let

1. \( \mathbb{R}^{d,1|N_{irr}} \in \text{Ho} (\text{SuperSpaces}_{\mathbb{R}}) \) be one of the super Minkowski spacetimes from Example 3.37, for \( N_{irr} \) irreducible (i.e. for \( N = 1 \), see Remark A.5);

2. \( B^{p+2} \mathbb{R} \in \text{Ho} (\text{SuperSpaces}_{\mathbb{R}}) \) be the image of the Eilenberg MacLane space of degree \( p+2 \) in rational spaces (Example A.22), regarded as a superspace via Example 3.31.

Then there are nontrivial maps of the form

\[
\mathbb{R}^{d,1|N} \xrightarrow{\mu_{p+2}} B^{p+2} \mathbb{R} \quad \in \text{Ho} (\text{SuperSpaces}_{\mathbb{R}})
\]

in the homotopy category of rational super spaces (Def. 3.30), hence, by Example A.22, cohomology class of nontrivial Spin-invariant cocycles in \( \text{CE}(\mathbb{R}^{10,1|N}) \) ([33]),

\[
[\mu_{p+2}] \in H^{p+2}(\mathbb{R}^{p,1|N})^{\text{Spin}(p,1)}
\]

precisely for the combinations \((d,p)\) that are checked in Table B. Moreover, for each entry, there is precisely one such map, up to rescaling by \( \mathbb{R} \setminus \{0\} \), and, via the translation in Example A.22, it is represented by the element of the form

\[
\mu_{p+1} \propto \frac{1}{p!} \psi \Gamma_{a_1 \cdots a_p} \psi \wedge e^{a_1} \wedge \cdots \wedge e^{a_p} \in \text{CE}(\mathbb{R}^{d+1|N_{irr}}),
\]

where we are using spinor notation as in Prop. A.3 We call these elements the fundamental \( p \)-brane cocycles.
Example 3.40 (Fundamental superstring cocycles).

(i) On the $D = 10, N = 1$ super Minkowski spacetime $\mathbb{R}^{10,1|16}$ from Example 3.37, the old brane scan (Prop. 36) recognizes a cocycle for a fundamental 1-brane, corresponding to the entry $(D = 9 + 1, p = 1)$ in Table B:

\[ \mathbb{R}^{9,1|16} \xrightarrow{\mu_{F1}^{H/I}} B^3 \mathbb{R} \xrightarrow{\sim_0} S^3 \]

This corresponds to the fundamental heterotic string or type I string (see Section 2 for terminology).

(ii) On the $D = 3, N = 1$ super Minkowski spacetime $\mathbb{R}^{2,1|2}$ from Example 3.37, the old brane scan (Prop. 36) recognizes a cocycle for a fundamental 1-brane, corresponding to the entry $(D = 2 + 1, p = 1)$ in Table B:

\[ \mathbb{R}^{2,1|2} \xrightarrow{\mu_{F1}^{D=3}} B^3 \mathbb{R} \xrightarrow{\sim} S^2 \]

In both cases we have indicated on the right that, as a morphism in $\text{Ho}(\text{SuperSpaces}_\mathbb{R})$, these cocycles may equivalently be regarded as taking values in suitable spheres, by Example A.21 and Example 3.31. These re-identifications of rational coefficients will be used in statement and proof of Theorem 6.1 below.

Remark 3.41 (Recognizing fundamental brane cocycles via normed division algebra). For checking that the 1-brane cochains (36) in dimensions 3, 4, 6, 10, and the 2-brane cochains in dimensions 4, 5, 6, 11 are indeed cocycles, as claimed by the Old Brane Scan (Prop. 3.39) it is useful to represent the corresponding real spinor representations in terms of normed division algebra, as briefly explained in Sect. A.1. This streamlined computation is spelled out in [BH10, BH11].

In fact, super Minkowski spacetimes carry more Spin-invariant cocycles than seen by the old brane scan (Prop. 3.39); albeit not in ordinary cohomology, but in generalized cohomology (Def. A.24).

Definition 3.42 (M-brane super-cochains [FSS16b, Def. 4.2]). Consider the $D = 11, N = 1$ super Minkowski spacetime $\mathbb{R}^{10,1|32}$ from Example 3.37. We say that the M-brane super-cochains are the following two elements in the corresponding DGC-superalgebra $\text{CE}(\mathbb{R}^{10,1|32})$

\[ \mu_{M2} := \frac{i}{2} \overline{\psi} \Gamma_{a_1 a_2} \psi \wedge e^{a_1} \wedge e^{a_2}, \]

\[ \mu_{M5} := \frac{i}{5!} \overline{\psi} \Gamma_{a_1 \ldots a_5} \psi \wedge e^{a_1} \wedge \ldots \wedge e^{a_5}, \]

where we are using spinor notation as in Prop. A.3.

Observe that, by Prop. 3.39, $\mu_{M2}$ is a cocycle in ordinary cohomology of degree 4, but not $\mu_{M5}$ is not a cocycle by itself.

Our investigations below revolve around the following exceptional structure in the rational super homotopy theory, see Section 2.1 for discussion of its physical meaning.

Proposition 3.43 (M2/M5-brane cocycle in rational super cohomotopy ([FSS16b, Prop. 4.3], [FSS16a, Cor. 2.3])). The M-brane super-cochains $\mu_{M2}, \mu_{M5}$ from Def. 3.42 constitute a cocycle on $D = 11$ super Minkowski spacetimes (Example 3.37) with values in degree four rational cohomotopy (Example 3.33), as follows:

\[ \mathbb{R}^{10,1|32} \xrightarrow{\mu_{M2/M5}} S^4 \xrightarrow{\in} \text{Ho}(\text{SuperSpaces}_\mathbb{R}). \]

Here on the right $\omega_4, \omega_7$ are the two generators of the minimal dgc-algebra model for the 4-sphere, from Example A.21, and as a homomorphism of dgc-superalgebras, $\mu_{M2/M5}$ takes them to the two M-brane cochains $\mu_{M2}, \mu_{M5}$ from Def. 3.42, respectively.
Now we turn to the equivariant refinement of rational super homotopy theory:

**Definition 3.44** ($G$-equivariant abstract homotopy theory). Let $(\mathcal{C}, W)$ be a homotopy theory embodied by a category with weak equivalences (Def. A.13), and let $G$ be a finite group. Then the corresponding $G$-equivariant homotopy theory is the category

$$PSh(\text{Orb}_G; \mathcal{C}) = \left\{ \begin{array}{c}
\text{Orb}^{\text{op}}_G \\
\text{G/H} \\
\text{G/H}
\end{array} \xrightarrow{X(-)} \begin{array}{c}
\mathcal{C} \\
\text{X(H1)} \\
\text{X(H2)}
\end{array} \right\}$$

(39)

of systems $X(-)$ of objects $X(H)$ of $\mathcal{C}$ parameterized by the category of orbit spaces $\text{G/H}$ of the group $G$ (Def. 3.20) whose weak equivalences are those natural transformations (3.23)

$$X_1(-) \xrightarrow{F(-)} X_2(-)$$

(40)

such that for each subgroup $H \subset G$ the component $F(H)$ (25) is a weak equivalence of $\mathcal{C}$ (an element of $W$). The resulting homotopy category (Def. A.14) we denote by

$$\text{Ho}(G\mathcal{C}) := \text{Ho}\left(\text{PSh}(\text{Orb}_G; \mathcal{C}) \left[\{\text{subgroup-wise weak equivalences of } \mathcal{C}\}^{-1}\right]\right).$$

The operation that extracts from systems (39) of fixed point loci in $\mathcal{C}$ just the total spaces, hence “forgetting” the group action, constitutes a “forgetful functor” from $G$-equivariant abstract homotopy theory to the underlying plain homotopy theory:

$$X(-) \in \text{Ho}(G\mathcal{C}) \xrightarrow{\text{forget equivariance}} X(1) \in \text{Ho}(\mathcal{C})$$

(41)

**Example 3.45** (Equivariant rational homotopy theory). The construction in Def. 3.44 applied to dg-algebraic homotopy theory (Def. A.19) yields the homotopy theory shown on the right in (42). The Sullivan equivalence (Prop. A.20) extends to exhibit this as equivalent to the corresponding rational version of $G$-equivariant homotopy theory.

$$\text{Ho}(G\text{Spaces}_{\mathbb{Q}, \text{nil}, \text{fin}}) \simeq \text{Ho}\left(\text{PSh}(\text{Orb}_G, \text{dgAlg}^{\text{op}}_{\text{cn}, \text{fin}}) \left[\{\text{subgroup-wise quasi-isomorphisms}\}^{-1}\right]\right).$$

(42)

This is the DG-algebraic model for *equivariant rational homotopy theory*, discussed in [Scu01][May+96 Ch. III][AP93 Sec. 3.3 & 3.4].

The super-geometric homotopy theory that we need here is now obtained from Example 3.45 by generalizing dgc-algebras to dgc-superalgebras (Def. 3.30):

**Definition 3.46** ($G$-equivariant rational super homotopy theory). For $G$ a finite group (or, more generally, a compact Lie group) the $G$-equivariant rational super homotopy theory is the result of applying the general construction of $G$-equivariant homotopy theory from Def. 3.45 to the rational super homotopy theory of Def. 3.30:

$$\text{Ho}(G\text{SuperSpaces}_{\mathbb{R}, \text{nil}, \text{fin}}) := \text{Ho}\left(\text{PSh}(\text{Orb}_G, dgc\text{SuperAlg}^{\text{op}}_{\text{cn}, \text{fin}}) \left[\{\text{subgroup-wise quasi-isomorphisms}\}^{-1}\right]\right).$$
Example 3.47 (G-Spaces as G-Superspaces). Let $G$ be a finite group and let $A$ be a $G$-space (Def. 3.7) such that for all subgroups $H \subset X$ the fixed point space $A^H$ (Def. 3.4) is nilpotent and of finite rational type (Def. A.18). Then the Sullivan equivalence (Prop. A.20) implies that the system of fixed point spaces (Example 3.24) of the rationalization of $A$, is equivalently given by the corresponding system of tuples of connected finite-type dgc-algebras

$$
\begin{align*}
G/H_1 & \to O(A^{H_1}) \\
O(A^{(-)}) : [g] & \downarrow & O(A^{[g]}) \\
G/H_2 & \to O(A^{H_2})
\end{align*}
$$

By Example 3.31 this defines a rational $G$-superspace, which we will denote by the same symbol:

$$A \in \text{Ho}(G\text{SuperSpaces}_\mathbb{R}).$$

Example 3.48 (Super Lie algebras with $G$-action as $G$-Superspaces). Let $g \simeq \mathbb{R}g_{\text{even}} \oplus g_{\text{odd}}$ be a finite-dimensional super Lie algebra, regarded as a rational superspace as in Example 3.34. Consider an action of a finite group $G$ on $g$ by super Lie algebra automorphisms

$$\rho(g) : g \to g, \quad g \in G.$$

These are equivalently linear actions on the underlying real vector spaces $g_{\text{even}}$ and $g_{\text{odd}}$, respecting the super Lie bracket. Hence, for each subgroup $H \subset G$, the fixed point spaces (21) constitute a super Lie subalgebra:

$$g^H \simeq (g_{\text{even}})^G \oplus (g_{\text{odd}})^G \subset g.$$

As in Example 3.22 (23), this yields a system of fixed super Lie algebras, indexed by the orbit category (Def. 3.20):

$$\text{Orb}_G^{op} \xrightarrow{g^{(-)}} \text{SuperLieAlg}$$

As in Example 3.22 (23), this represents a $G$-superspace (Def. 3.46), which we will denote by the same symbol (see Remark 3.35):

$$g \in \text{Ho}(G\text{SuperSpaces}_\mathbb{R}).$$

Finally we may combine these examples to say what it means to enhance super-cocycles to equivariant rational super homotopy theory (see Def. 3.28 and Remark 3.29 for the corresponding discussion in plain homotopy theory):

Example 3.49 (Equivariant enhancement of super-cocycles). Consider

- $g \in \text{SuperLieAlg} \to \text{Ho}(\text{SuperSpaces}_\mathbb{R})$ a super Lie algebra, regarded as a superspace via Example 3.34,
- $A \in \text{Spaces}_{\text{nil,fin}} \to \text{Ho}(\text{SuperSpaces}_\mathbb{R})$ a nilpotent space of finite rational type, regarded as a superspace via Example 3.31,
- $g \xrightarrow{\mu} A \in \text{Ho}(\text{SuperSpaces}_\mathbb{R})$ a morphism between these in the homotopy category, hence (Def. A.24) a class in the super rational $A$-cohomology of $g$.

Then for $G$ a finite group, a $G$-equivariant enhancement of $\mu$ is a lift through the forgetful functor (41)

$$
\begin{align*}
g \xrightarrow{\mu} A & \in \text{Ho}(G\text{SuperSpaces}_\mathbb{R}) \\
& \downarrow \text{forget } G\text{-equivariance} \\
g \xrightarrow{\mu} A & \in \text{Ho}(\text{SuperSpaces}_\mathbb{R})
\end{align*}
$$

By unwinding Def. 3.44 such an enhancement amounts to and encodes all of the following extra data:
1. a system $A(\cdot)$ of super-spaces indexed by the orbit category, with $A(1) = A$ the given coefficient object, for example given by an actual $G$-space structure on $A$ (Def. 3.7) on the topological space $A$, via Example 3.47.

2. a system $g(\cdot)$ of super-spaces indexed by the orbit category, with $g(1) = g$ the given domain object, for example given be an actual action of $G$ by super Lie algebra automorphisms, as in Example 3.48.

3. compatible $G$-equivariant cocycle structure on $\mu$, which means:
   (a) for each non-trivial subgroup $H \subset G$ a super-cocycle of the form
   \[ \mu(H) : g(H) \to A(H) \in \text{Ho}(\text{SuperSpaces}_R) \]
   (b) for each $G$-equivariant map $G/H_1 \to G/H_2$ between orbit spaces a choice of homotopy\(^{14}\)
   \[
   \begin{array}{ccc}
   G/H_1 & \xrightarrow{g} & g(H_1) \xrightarrow{\mu(H_1)} A(H_1) \\
   f \downarrow & & \downarrow \mu(f) \\
   G/H_2 & \xrightarrow{g} & g(H_2) \xrightarrow{\mu(H_2)} A(H_2)
   \end{array}
   \]
   such that the assignment $f \mapsto \mu(f)$ respects composition and identities.

In particular we may study the possible equivariant enhancements, as in Example 3.49 of the M2/M5-brane cocycle from Prop. 3.43. This is what we turn to next.

4 Real ADE-Singularities in Super-spacetimes

Here we classify finite group actions on 11-dimensional superspacetime $\mathbb{R}^{10,1|32}$ (Def. 3.36) which have the same bosonic fixed locus as an involution (this is Prop. 4.7 below), and whose fixed point locus is at least $\geq 1/4$-BPS (Def. 3.38). Using results of [MedFig+09], [MedFig09, Section 8.3], these are, if orientation-preserving, given by subgroups of SU(2), hence by finite groups in the ADE-series (this is Prop. 4.15 below). We collect this classification as Theorem 4.3 below. The corresponding quotient spaces are a supergeometric refinement of the du Val singularities in Euclidean space, briefly reviewed in Section 2.6 below. By intersecting several such simple singularities one obtains more actions of interest. Some of these non-simple ‘super singularities’ we discuss in Prop. 4.19. In the following Section 6 we see how these fixed point superspaces appear as part of the data of the equivariant cohomotopy of 11d superspace. Earlier, in Section 2.1 we gave a physical interpretation of these results: we interpret them as black brane species localized at singularities.

In what follows, as we work with the super Minkowski spacetimes $\mathbb{R}^{p,1|N}$, we will often refer to the even part $\mathbb{R}^{p,1}$ as bosonic and the odd part $\mathbb{N}$ as fermionic.

**Definition 4.1** (Super singularities). Let $G$ be a finite group acting on super-Minkowski spacetime $\mathbb{R}^{p,1|N}$ (Def. 3.36) by isometries (Example 3.48). If every non-trivial subgroup $\{e\} \neq H \subset G$ has the same bosonic fixed space, we say that this action exhibits a simple singularity. Otherwise we call it non-simple.

**Example 4.2** (Systems of fixed subspaces and brane intersections). Consider a system of fixed subspaces $\mathbb{R}^{10,1|32}(\cdot)$ indexed by the orbit category (Def. 3.20), that corresponds to a given action on super Minkowski spacetime (Example 3.48).

In terms of this systems of fixed subspaces, the singularity is simple, according to Def. 4.1 if the system of underlying bosonic subspaces is a constant functor on the orbit category, away from the trivial subgroup.

---

\(^{14}\) This follows by representing fibrant resolutions in terms of homotopies, as in Example 3.27 (29),(30)
We may interpret a simple singularity as reflecting an ‘elementary brane’.

**System of fixed subspaces of a simple singularity**, in the special case that not only the bosonic fixed space, but also the preserved spinors are independent of which non-trivial subgroup acts (for instance the case of the MK6 in Theorem 4.3).

On the other hand, a non-simple singularity corresponds to a system of fixed subspaces that is non-constant even away from the trivial subgroup. Here is such a functor:

```
Orb\_G^{op} \quad \mathbb{R}^{10,1|32} \quad \text{SuperSpaces}_\mathbb{R}
```

```
\xymatrix{ G/\{e\} \ar@{->}[r] & G/H_1 \ar@{->}[r] & \cdots \ar@{->}[r] & G/H_n \ar@{->}[r] & \mathbb{R}^{p,1|N_1} \ar@{->}[r] & \cdots \ar@{->}[r] & \mathbb{R}^{p,1|N_n} \\
G/G \ar@{->}[u] & \mathbb{R}^{p,1|N_{int}} \\

\xymatrix{ G/G \ar@{->}[u] & \mathbb{R}^{p,1|N_{int}} \\
G/G \ar@{->}[u] & \mathbb{R}^{p,1|N_{int}} }
```

We have labeled the subspace \(\mathbb{R}^{p,1|N_{int}}\), fixed by the entire group action, by int for intersection. This is because we interpret non-simple singularities as ‘intersecting branes’.

**System of fixed super subspaces of a non-simple singularity.** The fixed locus \(\mathbb{R}^{p,1|N_{int}}\) of the full group \(G\) is exhibited as the non-trivial intersection of fixed loci of some non-trivial subgroups \(H_k\), as in Def. 4.18 below, for instance the intersection \(M2 \dashv M5\) in Prop. 4.19 below.

In the following, the notation \((\mathbb{Z}_2)_{L,R}\) refers to the induced action of the center of SU(2)_{L,R}, while \(\tilde{f}\) denotes a subgroup inclusion factoring through a given group homomorphism \(f\). We will also encounter \(\Delta\), which denotes the diagonal, and \(\tau\) which denotes a non-trivial outer automorphism.
| Black brane species | BPS | Fixed locus in $\mathbb{R}^{10,1/2}$ | Type of singularity in $\mathbb{R}^{10,1}$ | Intersection law |
|---------------------|-----|-----------------------------------|---------------------------------|-----------------|
| MO9 | $1/2$ | $\mathbb{R}^{0,1|16}$ | $Z_2$ = $\mathbb{R}^{2,1|4}/2$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| M5 | $1/2$ | $\mathbb{R}^{5,1|2|8}$ | $Z_2 \subset (Z_2)_R \times (Z_2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| MW | $1/2$ | $\mathbb{R}^{6,1|16}$ | $Z_n+3 \subset (Z_2)_L \times (Z_2)_R \times (Z_2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| MK6 | $1/2$ | $\mathbb{R}^{6,1|16}$ | $Z_{n+1}, 2D_{n+2}, 2T; 2O; 2I \subset (Z_2)_L \times (Z_2)_R \times (Z_2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| M2 | $1/2$ | $\mathbb{R}^{6,1|16}$ | $Z_2 \subset SU(2)_L \times SU(2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| M2 | $6/16$ | $\mathbb{R}^{2,1|4}/2$ | $Z_2 \subset SU(2)_L \times SU(2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| M2 | $5/16$ | $\mathbb{R}^{5,1|5|2}$ | $Z_{n+1} \subset SU(2)_L \times SU(2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |
| M2 | $4/16$ | $\mathbb{R}^{3,1|4}/2$ | $Z_{n+1} \subset SU(2)_L \times SU(2)_R$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4$ |

Table 1. Singularities in $D = 11, \mathcal{N} = 1$ super Minkowski spacetime. The *simple* singularities in the top half (Def. 4.1) are classified by Theorem 4.3. The *non-simple* singularities in the bottom part are the intersections of the former, established in Prop. 4.19. The label “black brane species” attached with each type of singularity is explained in Sec. 2.1. The symbol “$\perp$” indicates that two intersecting fixed loci are parallel, in that one is contained in the other. Otherwise we use “$\parallel$” to indicate that they are perpendicular to each other.
4.1 Simple super singularities and Single black brane species

**Theorem 4.3** (Classification of simple real singularities in 11d super-Minkowski spacetime). The following table classifies, up to conjugacy in $\text{Pin}^+(10,1)$, the $\geq 1/4$ BPS (Def. 3.38) simple singularities (Def. 4.1) in $D = 11$, $N = 1$ super Minkowski super spacetime (Example 3.37) that are fixed (Example 3.48) at least by a non-trivial $\mathbb{Z}_2$-action (as in Def. 4.6 below).

| Black brane species | BPS | Fixed locus in $\mathbb{R}^{10,1|32}$ | Type of singularity in $\mathbb{R}^{10,1}$ | Intersection law |
|---------------------|-----|--------------------------------------|-------------------------------------------|-----------------|
| MO9                 | 1/2 | $\mathbb{R}^{9,1|16}$               | $\mathbb{Z}_2$                            | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4 \oplus \mathbb{R}^4 \oplus \mathbb{R}^1$ |
| M5                  | 1/2 | $\mathbb{R}^{5,1|2|8}$              | $\mathbb{Z}_2$                            | $(\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R$ |
| MW                  | 1/2 | $\mathbb{R}^{1,1|16}$              | $\mathbb{Z}_2$                            | $(\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R$ |
| MK6                 | 1/2 | $\mathbb{R}^{6,1|16}$              | $\mathbb{Z}_{n+1}, 2\mathbb{D}_{n+2}$, $2\mathbb{T}, 2\mathbb{O}, 2\mathbb{I}$ | $\mathbb{R}^{10,1}$ |
| M2                  | 1/2 = 8/16 | $\mathbb{R}^{2,1|8|2}$ | $\mathbb{Z}_2$ | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4 \oplus (\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R$ |
| M2                  | 6/16 | $\mathbb{R}^{2,1|6|2}$              | $\mathbb{Z}_{n+3}$                        | $\mathbb{R}^{1,1} \oplus \mathbb{R}^4 \oplus (\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R$ |
| M2                  | 5/16 | $\mathbb{R}^{2,1|5|2}$              | $2\mathbb{D}_{n+2}$, $2\mathbb{T}, 2\mathbb{O}, 2\mathbb{I}$ | $\mathbb{R}^{10,1}$ |
| M2                  | 1/4 = 4/16 | $\mathbb{R}^{2,1|4|2}$              | $2\mathbb{D}_{n+2}, 2\mathbb{T}, 2\mathbb{O}, 2\mathbb{I}$ | $\mathbb{R}^{10,1}$ |

Moreover, the actions on the underlying bosonic spacetime are as shown on the right of the table, induced by the vector space decomposition

$$\mathbb{R}^{10,1} \simeq \mathbb{R}^{1,1} \oplus \mathbb{R}^4 \oplus \mathbb{R}^4 \oplus \mathbb{R}^1,$$

where both copies of $\text{SU}(2)$ act via their defining action on $\mathbb{C}^2 \simeq \mathbb{R}^4$, while $(\mathbb{Z}_2)_L$ acts by multiplication by $-1$ on $\mathbb{R}^1$.

The proof of Theorem 4.3 is given by the combination of Proposition 4.7 and Proposition 4.15 below, to which we now turn.

**Definition 4.4** ($p$-brane involution). Consider an involution $\sigma \in \text{Pin}^+(10,1)$ acting canonically on $\mathbb{R}^{10,1}$ (as in Def. 4.1). As a linear transformation of $\mathbb{R}^{10,1}$, it may be diagonalized, with eigenvalues $\pm 1$:

$$\sigma = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

That is for some $p \in \mathbb{N}$, $\mathbb{R}^{10,1}$ decomposes into orthogonal subspaces

$$\mathbb{R}^{10,1} \simeq \mathbb{R}^{p,1} \oplus \mathbb{R}^{10-p},$$

such that $\sigma$ acts as $1$ on one summand and as $-1$ on the other. In fact, since $\sigma$ preserves time orientation, it acts as $1$ on the $\mathbb{R}^{p,1}$ summand, and $-1$ on the spacelike $\mathbb{R}^{10-p}$ summand. To highlight the natural number $p$, we call $\sigma$ a $p$-brane involution.

**Example 4.5** (Trivial $p$-brane involutions). For $p = 10$, a $p$-brane involution (Def. 4.4) acts trivially on $\mathbb{R}^{10,1}$, so we say $\sigma$ is a trivial $p$-brane involution. For other values of $p$, we say $\sigma$ is nontrivial. A trivial $p$-brane involution $\sigma$ is just an element of the kernel of the double cover $\text{Pin}^+(10,1) \to \text{O}^+(10,1)$, so $\sigma = \pm 1$.

**Definition 4.6** ($\mathbb{Z}_2$-actions by $p$-brane involutions on 11d super-Minkowski spacetime). Any $p$-brane involution (Def. 4.4) defines an action of the group $\mathbb{Z}_2$ (Example 3.3) on $\mathbb{R}^{10,1|32} \in \text{Ho}(\text{SuperSpaces}_\mathbb{R})$ (Example 3.37) by super Lie algebra automorphisms (Example 3.48).
Proposition 4.7 (Classification of $\mathbb{Z}_2$-actions on 11d super-Minkowski spacetime). The $\mathbb{Z}_2$-actions on $\mathbb{R}^{10,1|32}$ according to Def. 4.6, are, up to conjugacy in $\text{Pin}^+(10,1)$, in bijection with the entries in the following table:

| Black brane species | BPS | Singular locus $\subset \mathbb{R}^{10,1|32}$ | Type of singularity | Intersection law |
|---------------------|-----|-------------------------------------|-----------------|-----------------|
| MO9                 | $\frac{1}{2}$ | $\mathbb{R}^{9,1|16}$ | $\mathbb{Z}_2$ | $\equiv (\mathbb{Z}_2)_{HW}$ |
| M5                  | $\frac{1}{2}$ | $\mathbb{R}^{5,1|2\cdot8}$ | $\mathbb{Z}_2$ | $\Delta \cneq (\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_{HW}$ |
| MW                  | $\frac{1}{2}$ | $\mathbb{R}^{1,1|16\cdot1}$ | $\mathbb{Z}_2$ | $\Delta \cneq (\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R \times (\mathbb{Z}_2)_{HW}$ |
| MK6                 | $\frac{1}{2}$ | $\mathbb{R}^{6,1|16}$ | $\mathbb{Z}_2$ | $\equiv (\mathbb{Z}_2)_L$ |
| M2                  | $\frac{1}{2}$ | $\mathbb{R}^{2,1|8\cdot2}$ | $\mathbb{Z}_2$ | $\Delta \cneq (\mathbb{Z}_2)_L \times (\mathbb{Z}_2)_R$ |

The proof of Prop. 4.7 is by the following series of lemmas:

Lemma 4.8 (Existence of p-brane involutions). If $\sigma \in \text{Pin}^+(10,1)$ is a p-brane involution (Def. 4.4), then $p \equiv 1$ or 2 mod 4. Conversely, if $p \equiv 1$ or 2 mod 4, then for any orthogonal decomposition of $\mathbb{R}^{10,1}$ of the form

$$\mathbb{R}^{10,1} \cong \mathbb{R}^{p,1} \oplus \mathbb{R}^{10-p}$$

there is a p-brane involution acting as 1 on the first summand and $-1$ on the second. Hence, there are p-brane involutions $\sigma$ precisely for $p = 1, 2, 5, 6, 9$ and 10, though for $p = 10$, $\sigma$ is trivial (in the sense of Def. 4.4).

Proof. Let $\sigma$ be a p-brane involution, and let $\mathbb{R}^{10-p}$ be the subspace of $\mathbb{R}^{10,1}$ on which $\sigma$ acts as $-1$. Writing $q := 10 - p$ for brevity, let $\{b_1, \ldots, b_q\}$ be an orthonormal basis of $\mathbb{R}^{10-p}$. Then the Clifford algebra element $b_1 \cdots b_q$ lies in $\text{Pin}^+(10,1)$ and acts on $\mathbb{R}^{p,1}$ as 1 and on $\mathbb{R}^{10-p}$ as $-1$. Because $\text{Pin}^+(10,1)$ is a double cover of $O^+(10,1)$ with kernel $\{1, -1\}$, this implies $\sigma = \pm b_1 \cdots b_q$. Since, as elements of the Clifford algebra, the vectors $b_1, \ldots, b_q$ square to 1 and anticommute with each other, we compute:

$$\sigma^2 = (-1)^{\frac{q(q-1)}{2}} b_1^2 \cdots b_q^2 = \pm 1.$$

This gives 1 if and only if $q \equiv 0$ or 1 mod 4, which implies $p \equiv 1$ or 2 mod 4.

Conversely, if $p \equiv 1$ or 2 mod 4, choose an orthogonal decomposition of $\mathbb{R}^{10,1}$ of the form:

$$\mathbb{R}^{10,1} \cong \mathbb{R}^{p,1} \oplus \mathbb{R}^{10-p}.$$

As above, let $\{b_1, \ldots, b_q\}$ be an orthonormal basis of $\mathbb{R}^{10-p}$. The same calculation as above shows that $\sigma = b_1 \cdots b_q$ is the desired p-brane involution. \hfill \square

Lemma 4.9 (Conjugacy of p-brane involutions). All nontrivial p-brane involutions (Def. 4.4) for given $p = 1, 2, \text{mod 4}$ (Lemma 4.8) are conjugate by an element of $\text{Pin}^+(10,1)$.

Proof. Let $\sigma, \sigma' \in \text{Pin}^+(10,1)$ be two nontrivial p-brane involutions. Then $p \leq 9$, and $\mathbb{R}^{10,1}$ decomposes into an orthogonal direct sum:

$$\mathbb{R}^{10,1} \cong \mathbb{R}^{p,1} \oplus \mathbb{R}^{10-p}$$

on which $\sigma$ acts diagonally. Write $q := 10 - p$ for brevity, and let $\{b_1, \ldots, b_q\}$ be an orthonormal basis of the $\mathbb{R}^{10-p}$ summand. Then the Clifford algebra element $b_1 \cdots b_q$ lies in $\text{Pin}^+(10,1)$ and acts on $\mathbb{R}^{10,1}$ in the same way $\sigma$ does. Thus $\sigma = \pm b_1 \cdots b_q$, and changing the sign of a basis vector if necessary, with can assume $\sigma = b_1 \cdots b_q$. Similarly, we can find $q$ spacelike orthonormal vectors $\{b'_1, \ldots, b'_q\}$ such that $\sigma' = b'_1 \cdots b'_q$.

We may now extend the set of $q$ orthonormal vectors $\{b_1, \ldots, b_q\}$ to a time-oriented orthonormal basis of $\mathbb{R}^{10,1}$, and similarly for the $q$ orthonormal vectors $\{b'_1, \ldots, b'_q\}$. There is a unique element of $O^+(10,1)$ taking one basis to the other, and this lifts to an element $g \in \text{Pin}^+(10,1)$ that maps $b_i \mapsto b'_i$ for all $1 \leq i \leq q$. 

43
Let us write the double covering map \( R: \text{Pin}^+(10, 1) \to \text{O}^+(10, 1) \). Then by construction:

\[
R(g)R(\sigma)R(g^{-1}) = R(\sigma').
\]

Thus, in \( \text{Pin}^+(10, 1) \), we must have either \( g\sigma g^{-1} = \sigma' \), or \( g\sigma g^{-1} = -\sigma' \). In the first case, we are done. In the second, if we can find an element \( h \in \text{Pin}^+(10, 1) \) that anticommutes with \( \sigma \), and redefine \( g \) to be \( gh \), we are done.

Let us find \( h \in \text{Pin}^+(10, 1) \) that anticommutes with \( \sigma \). That is, that satisfies \( hgh^{-1} = -\sigma \). If \( q = 10 - p \) is odd, we can take any spacelike unit vector \( v \) orthogonal to the basis \( \{b_1, \ldots, b_q\} \). Then \( h = v \) anticommutes with \( \sigma \). If \( q \) is even, we can choose \( h = b_1 \). This completes the proof. \( \square \)

Now we compute the fixed loci of \( p \)-brane involutions one by one, according due to their essentially unique existence established by Lemma 4.8 and Lemma 4.9.

**Lemma 4.10** (Fixed locus of the 1-brane involution). Let \( \sigma \) be a 1-brane involution (Def. 4.4). It fixes the \( D = 1 + 1 \), \( N = (16, 0) \) super-Minkowski subalgebra:

\[
\mathbb{R}^{1,1|16-1} + \left( \mathbb{R}^{10,1|32} \right)^{\sigma}.
\]

Here, \( 1_+ \) denotes the 1-dimensional real spinor representation of

\[
\text{Spin}(1, 1) = \{\exp(\frac{i}{2}\Gamma_{01}) : t \in \mathbb{R}\}
\]
on which the group element \( \exp(\frac{i}{2}\Gamma_{01}) \) acts by multiplication by \( e^{it} \) (Example A.4). Moreover, the bilinear spinor pairing (71) in \( \mathbb{R}^{1,1|16-1} \) spans the lightlike subspace \( \langle b_0 + b_1 \rangle \subseteq \mathbb{R}^{1,1} \):

\[
\text{im}(16 \cdot 1_+ \otimes 16 \cdot 1_+) \cong \mathbb{R}^{1,1} = \text{span}\{b_0 + b_1\} \subseteq \mathbb{R}^{1,1}.
\]

**Proof.** Since all 1-brane involutions are conjugate, by Lemma 4.9 we may choose:

\[
\sigma = -\Gamma_{2345678910}.
\]

The minus sign ensures that we will get the spinor representation \( 1_+ \) of the lemma above, rather than the other spinor representation \( 1_- \) on which \( \exp(\frac{i}{2}\Gamma_{01}) \) acts as \( e^{-it} \). The two are related, of course, by an element of \( \text{Pin}^+(10, 1) \).

Clearly, \( \sigma \) fixes the bosonic subspace \( \mathbb{R}^{1,1} = \langle b_0, b_1 \rangle \). To see which fermionic subspace it fixes, we make use of the octonionic presentation of the \( 32 \) of \( \text{Pin}^+(10, 1) \) from Example A.12. Multiplying out the \( \Gamma \)-matrices (81), we see that \( \sigma \) acts on \( 32 \simeq \mathbb{O}^4 \) as the diagonal matrix:

\[
\sigma = \text{diag}(-1, 1, 1, -1)
\]

Thus the space of spinors fixed by \( \sigma \) is:

\[
S = \{(0, a, b, 0) \in \mathbb{O}^4\}.
\]

Since \( \Gamma_{01} = \text{diag}(-1, 1, 1, -1) \) then \( \text{Spin}(1, 1) \) acts on \( S \) as \( 16 \cdot 1_+ \). Thus, as a representation of \( \text{Spin}(1, 1) \), the fixed point locus is indeed \( \mathbb{R}^{1,1|16-1} \).

Finally, note that \( \mathbb{R}^{1,1} \) is not an irreducible representation of \( \text{Spin}(1, 1) \). It decomposes into the sum of two lightlike subrepresentations:

\[
\mathbb{R}^{1,1} \simeq \text{span}\{b_0 + b_1\} \oplus \text{span}\{b_0 - b_1\}.
\]

On the first summand, \( \exp(\frac{i}{2}\Gamma_{01}) \in \text{Spin}(10, 1) \) acts as \( e^t \), and on the second as \( e^{-t} \). It is thus immediate from the \( \text{Spin}(1, 1) \)-equivariance of the bracket operation that the bracket of spinors in \( \mathbb{R}^{1,1|16-1} \) lands in the first summand. The brackets of spinors span this 1-dimensional subspace as long as they are not all zero, which we leave to the reader. \( \square \)
Lemma 4.11 (Fixed locus of the 2-brane involution). Let \( \sigma \) be a 2-brane involution (Def. 4.4). Then it fixes the \( D = 2 + 1 \), \( N = 8 \) super-Minkowski subalgebra:

\[
\mathbb{R}^{2,1|\mathbb{8}^2} \cong (\mathbb{R}^{10,1|\mathbb{32}})_{\sigma}.
\]

Proof. Since all 2-brane involutions are conjugate, by Lemma 4.9 we may choose: \( \sigma = \Gamma_{23456789} \). This clearly fixes the bosonic subspace \( \mathbb{R}^{2,1} \cong \text{span}\{b_0, b_1, \ldots, b_{10}\} \).

In order to compute the fermionic fixed space, we make use of the octonionic presentation of the \( \mathbf{32} \) of \( \text{Pin}^+(10,1) \) from Example A.12. Multiplying out the \( \Gamma \) matrices, we see that \( \sigma \) acts on \( \mathbf{32} \cong \mathbb{O}^4 \) as the diagonal matrix:

\[
\sigma = \text{diag}(1, -1, 1, -1).
\]

It thus fixes the 16-dimensional space of spinors

\[
S \cong \{(a, 0, b, 0) \in \mathbb{O}^4\}.
\]

Because \( \text{Spin}(2,1) \) has a unique 2-dimensional real spinor representation (Prop. A.11), we must have \( S \cong \mathbf{8} \cdot \mathbf{2} \). Thus the fixed point locus is the super-Minkowski subalgebra \( \mathbb{R}^{2,1|\mathbb{8}^2} \).

A brief indication of the following argument may be found in [Wit95] Sec. (2.1), see Example 2.3 below.

Lemma 4.12 (Fixed locus of the 5-brane involution). Let \( \sigma \) be a 5-brane involution (Def. 4.4). Then it fixes the \( D = 5 + 1 \), \( N = (2,0) \) super-Minkowski subalgebra:

\[
\mathbb{R}^{5,1|\mathbb{8}^8} \cong (\mathbb{R}^{10,1|\mathbb{32}})_{\sigma}.
\]

Proof. Since all 5-brane involutions are conjugate by Lemma 4.9 we may choose: \( \sigma = \Gamma_{678910} \). This clearly fixes the bosonic subspace \( \mathbb{R}^{5,1} = \text{span}\{b_0, b_1, \ldots, b_5\} \).

In order to compute the fermionic fixed space, we make use of the octonionic presentation of the \( \mathbf{32} \) of \( \text{Pin}^+(10,1) \) from Example A.12. Multiplying out the \( \Gamma \) matrices, we see that \( \sigma \) acts on \( \mathbf{32} \cong \mathbb{O}^4 \) as the diagonal matrix:

\[
\sigma = \text{diag}(\theta, \theta, -\theta, -\theta)
\]

where each \( \theta \) is the linear transformation of \( \mathbb{O} \) given by \( \theta = L_{e_4}L_{e_5}L_{e_6}L_{e_7} \); that is, by successive left multiplication by the imaginary octonions \( e_4, e_5, e_6 \) and \( e_7 \). Conjugating by an element in \( \text{Pin}^+(10,1) \) if necessary, we can order the \( \Gamma \) matrices and thus the basis of \( \text{Im} \mathbb{O} \) so that \( e_1 = i, e_2 = j \) and \( e_3 = k \) are the imaginary units of a quaternionic subalgebra \( \mathbb{H} \subseteq \mathbb{O} \), while \( e_4 = \ell, e_5 = i\ell, e_6 = j\ell \) and \( e_7 = k\ell \) span the orthogonal complement \( \mathbb{H}\ell \subseteq \mathbb{O} \), where \( \ell \) is a unit imaginary octonion orthogonal to \( \mathbb{H} \). Using the Cayley–Dickson construction, we can check that \( L_{e_1}L_{e_2} \cdots L_{e_7} = -1 \) on \( \mathbb{O} \). We thus have \( \theta = L_{e_3}L_{e_2}L_{e_1} \). so that \( \theta = kji = 1 \) on \( \mathbb{H} \). We can compute that it is \(-1\) on \( \mathbb{H}\ell \). Consequently, the fixed fermionic subspace is:

\[
S = \mathbb{H}^2 \oplus \mathbb{H}^2\ell = (\mathbb{O}^4)_{\sigma}.
\]

By Prop. A.11, the action of \( \text{Spin}(5,1) \) on \( \mathbb{H}^2 \) is clearly as the representation \( \mathbf{8} \), since the \( \Gamma \) matrices \( \Gamma_0, \ldots, \Gamma_5 \) are quaternionic.

It is less clear that its action on \( \mathbb{H}^2\ell \) is again \( \mathbf{8} \), but this is still true. We use an argument from [HS17]. Consider the action of generators of \( \text{Spin}(5,1) \) on \( \mathbb{H}^2 \) and \( \mathbb{H}^2\ell \), respectively. A pair of unit vectors \( A, B \in \mathbb{R}^{5,1} \), viewed as \( 2 \times 2 \) Hermitian matrices over \( \mathbb{H} \), act on \( \psi \in \mathbb{H}^2 \) as \( \tilde{A}_L(B_L\psi) \), whereas they act on \( \psi\ell \in \mathbb{H}^2\ell \) as \( A_L(\tilde{B}_L(\psi\ell)) \). In both expressions the subscript \( L \) indicates that each matrix element of \( A \) and \( B \) acts by left multiplication. Yet we can use the Cayley–Dickson construction (Def. A.6) to see that

\[
A_L(\tilde{B}_L(\psi\ell)) = (A_R(\tilde{B}_R\psi))\ell,
\]

where \( \ell \) is the linear transformation of \( \mathbb{O} \) given by \( \ell = L_{e_4}L_{e_5}L_{e_6}L_{e_7} \); that is, by successive left multiplication by the imaginary octonions \( e_4, e_5, e_6 \) and \( e_7 \). Conjugating by an element in \( \text{Pin}^+(10,1) \) if necessary, we can order the \( \Gamma \) matrices and thus the basis of \( \text{Im} \mathbb{O} \) so that \( e_1 = i, e_2 = j \) and \( e_3 = k \) are the imaginary units of a quaternionic subalgebra \( \mathbb{H} \subseteq \mathbb{O} \), while \( e_4 = \ell, e_5 = i\ell, e_6 = j\ell \) and \( e_7 = k\ell \) span the orthogonal complement \( \mathbb{H}\ell \subseteq \mathbb{O} \), where \( \ell \) is a unit imaginary octonion orthogonal to \( \mathbb{H} \). Using the Cayley–Dickson construction, we can check that \( L_{e_1}L_{e_2} \cdots L_{e_7} = -1 \) on \( \mathbb{O} \). We thus have \( \theta = L_{e_3}L_{e_2}L_{e_1} \). so that \( \theta = kji = 1 \) on \( \mathbb{H} \). We can compute that it is \(-1\) on \( \mathbb{H}\ell \). Consequently, the fixed fermionic subspace is:

\[
S = \mathbb{H}^2 \oplus \mathbb{H}^2\ell = (\mathbb{O}^4)_{\sigma}.
\]
where the subscript $R$ indicates that matrix elements now act by right multiplication. Therefore, we are now reduced to showing that this right multiplication action

\[ \psi \mapsto A_R(B_R(\psi)) \]

is isomorphic to the left multiplication action with the position of the trace reversal exchanged:

\[ \psi \mapsto \tilde{A}_L(B_L(\psi)) . \]

We claim that such an isomorphism is established by $F$: $\psi \mapsto J\overline{\psi}$, with $J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. To see this, first note the relation $J\overline{A} = -\overline{A}J$ holds for any hermitian $2 \times 2$ matrix $A$, which follows from a quick calculation. This is then used to deduce that $F$ is an equivariant map:

\[
F(\tilde{A}_R(B_R(\psi))) = J \overline{A_R(B_R(\psi))} = J \overline{A_L(\overline{B_L(\psi)})} = A_L(\overline{B_L(F(\psi))}).
\]

In the second step, we have used that conjugation turns right multiplication into left multiplication. \hfill \square

**Lemma 4.13** (Fixed locus of the 6-brane involution). The $p$-brane involution $\sigma$ (Def. 4.4) for $p = 6$, which by Lemma 4.9 exists uniquely up to conjugacy, fixes the $D = 5 + 1, N = (2, 0)$ super Minkowski subalgebra (Example A.12)

\[
\mathbb{R}^{6,1|16} \cong (\mathbb{R}^{10,1|32})^\sigma.
\]

**Proof.** By Lemma 4.9 we may take $\sigma = \Gamma_{689}$. It is clear that the bosonic subspace of the corresponding fixed subalgebra is $\mathbb{R}^{6,1} = \text{span}\{b_0, b_1, \ldots, b_7, b_{10}\} \subset \mathbb{R}^{10,1}$. In order to compute the fermionic fixed space we use the octonionic presentation of $32$ from Example A.12: From (32) we get

\[
\Gamma_{689} = \varepsilon^4 \otimes J^4 L_{e_4} L_{e_5} L_{e_6} L_{e_7} = L_{e_4} L_{e_5} L_{e_6} L_{e_7} ,
\]

so that

\[
(\otimes^4)^\Gamma_{689} = \left((\otimes)^{L_{e_4} L_{e_5} L_{e_6} L_{e_7}}\right)^4.
\]

Let $\theta = L_{e_4} L_{e_5} L_{e_6} L_{e_7}$, that is the linear operator given by successive left multiplication by the unit imaginary octonions $e_4, \ldots, e_7$. This is the same linear transformation we studied in the proof of Lemma 4.13. As in that proof, reordering the basis of $\mathbb{R}^{10,1|32}$ by an element of $\text{Pin}^+(10, 1)$ if necessary, we can prove that the $\theta$ fixes a quaternionic subspace $\mathbb{H} \subset \mathbb{O}$. Thus $32^\sigma \cong \mathbb{H}^4$. Restricting to the group $\text{Spin}(6, 1)$, we use Prop. A.11 to conclude $\mathbb{H}^4 \cong 16$, and this completes the proof. \hfill \square

**Lemma 4.14** (Fixed locus of the 9-brane involution). Let $\sigma$ be a 9-brane involution (Def. 4.4). Then it fixes the $D = 9 + 1, N = 1$ super-Minkowski subalgebra:

\[
\mathbb{R}^{9,1|16} \cong (\mathbb{R}^{10,1|32})^\sigma.
\]

**Proof.** Since all 9-brane involutions are conjugate by Lemma 4.9 we may choose: $\sigma = \Gamma_{10}$. This clearly fixes the bosonic subspace $\mathbb{R}^{9,1} = \text{span}\{b_0, b_1, \ldots, b_9\}$. Moreover, $\Gamma_{10}$ acts diagonally on $32 \cong \mathbb{O}^4$:

\[
\Gamma_{10} = \text{diag}(1, 1, -1, -1).
\]

It thus fixes $\mathbb{O}^2 \cong \{(a, b, 0, 0) \in \mathbb{O}^4\}$. Examining the octonionic representation of $\text{Pin}^+(10, 1)$ via Prop. A.11 we see that $\text{Spin}(9, 1)$ acts on this $\mathbb{O}^2$ as $16$. \hfill \square
In summary, these lemmas constitute the proof of Prop. 4.7.

We now consider the generalization of the above $\mathbb{Z}_2$-actions on superspacetime to actions of larger groups, while retaining the fixed point locus of every non-trivial subgroup.

**Proposition 4.15** (Classification of $G_{ADE}$-actions fixing $M2$ and $MK6$). The two (up to conjugacy) orientation-preserving $\mathbb{Z}_2$-actions on $\mathbb{R}^{10,1|32}$ in Prop. 4.7 (those labeled $MK6$ and $M2$) extend to actions of all the finite subgroups of $SU(2)$ (Remark A.9) such that their fixed point locus retains the same bosonic part $\mathbb{R}^{p,1}$ ($p = 2, 6$, respectively) and is $\geq \frac{1}{4}$-$BPS$ (Def. 3.38) as shown in the following table:

| Black brane species | BPS | Singular locus $\subset \mathbb{R}^{10,1|32}$ | Type of singularity | Intersection law |
|---------------------|-----|-----------------------------------------------|---------------------|-----------------|
| MK6                 | $\frac{1}{2}$ | $\mathbb{R}^{6,1|16}$ | $\mathbb{Z}_{n+1}, 2\mathcal{D}_{n+2}, 2T, 2O, 2I$ | $\subset SU(2)_L$ |
| M2                  | $\frac{1}{2} = \frac{8}{16}$ | $\mathbb{R}^{2,1|8,2}$ | $\mathbb{Z}_2 \Delta \subset SU(2)_L \times SU(2)_R$ |
| M2                  | $\frac{6}{16}$ | $\mathbb{R}^{2,1|6,2}$ | $\mathbb{Z}_{n+3} \Delta \subset SU(2)_L \times SU(2)_R$ |
| M2                  | $\frac{5}{16}$ | $\mathbb{R}^{2,1|5,2}$ | $2\mathcal{D}_{n+2}, 2T, 2O, 2I \Delta \subset SU(2)_L \times SU(2)_R$ |
| M2                  | $\frac{1}{4} = \frac{4}{16}$ | $\mathbb{R}^{2,1|4,2}$ | $2\mathcal{D}_{n+2}, 2O, 2I \subset SU(2)_L \times SU(2)_R$ |

Moreover, this exhausts those actions such that every non-trivial subgroup fixes precisely a 6-brane, and it exhausts those actions such that every non-trivial subgroup fixes precisely a 2-brane in spacetime and is $\geq \frac{1}{4}$-$BPS$.

**Proof.** Consider the given bosonic fixed point inclusion $\mathbb{R}^{p,1} \hookrightarrow \mathbb{R}^{10,1}$. This induces a branching of the real spin representation $32$ along the correspondingly broken Spin group

$$\text{Spin}(10 - p) \xrightarrow{\nu} \text{Spin}(10, 1)$$

as a direct sum of irreps (see Example A.4) as follows:

$$32 \simeq \begin{cases} 
\mathbb{R}^2 \otimes (8 \oplus \bar{8}) & \in \text{Rep}(\text{Spin}(8)) \quad | \quad p = 2, \\
\mathbb{R}^{16} \otimes 4 & \in \text{Rep}(\text{Spin}(4)) \quad | \quad p = 6.
\end{cases}$$

This way the question is reduced to classifying the finite subgroups of Spin(8) and Spin(4) whose canonical action on $\mathbb{R}^8$ and $\mathbb{R}^4$, respectively, fixes only the origin (equivalently: whose action on the unit spheres $S^7 \simeq S(\mathbb{R}^8)$ and $S^3 \simeq S(\mathbb{R}^4)$ is free), and computing the fixed point subspaces of their action on the representation $8 \oplus \bar{8}$ of Spin(8) and 4 of Spin(4), respectively. Precisely these two classification problems has been solved in MedFig09 and in MedFig09 [Section 8.3], respectively. \[15\]

In fact the argument in MedFig09, Section 8.3 implies that all of SU(2) fixes the 6-brane, and all the non-trivial subgroups fix one and the same $1/2$-$BPS$ $\mathbb{R}^{6,1|16}$. For completeness, we now make this full SU(2)-action, fixing the 6-brane locus, fully explicit:

**Lemma 4.16** (6-brane locus fixed by Spin(2)). The super subspace $\mathbb{R}^{6,1|16} \hookrightarrow \mathbb{R}^{10,1|32}$ is fixed by every element in every Spin(2) subgroup of Spin(4) of the form

$$\text{Spin}(2) \simeq \{ \exp \left( \frac{1}{2} \Gamma_6 \Gamma_7 \right) \exp \left( -\frac{1}{2} \Gamma_8 \Gamma_9 \right) : t \in \mathbb{R} \}$$

where $\{ b_6, b_7, b_8, b_9 \}$ is an orthonormal basis of the subspace orthogonal to $\mathbb{R}^{6,1}$.

\[15\] The discussion in MedFig09 Section 8.3 is motivated by classifying supersymmetric supergravity solutions corresponding to the near horizon limit of black M5 branes, but ends up classifying fixed loci $\mathbb{R}^{6,1} \hookrightarrow \mathbb{R}^{10,1}$ corresponding to 6-branes, as in the above statement. In physics lingo, this reflects the phenomenon that multiple D6-branes end pairwise on NS5-branes. We discussed this subtle point in the physics interpretation in Section 2.2.
Proof. It is clear that the bosonic subspace $\mathbb{R}^{6,1}$ is fixed. We need to check that also the fermionic subspace is fixed. Setting $t = \pi$ in \((48)\), we see that the subgroup in question contains a 6-brane involution $\sigma = -\Gamma_{0789}$. We already know from Lemma \ref{Lemma.6.11} that this fixes $\mathbb{R}^{6,1}$. Since $\text{Spin}(2)$ is a connected 1-dimensional Lie group, generated by the single Lie algebra element $X = \Gamma_{67} - \Gamma_{89}$, it suffices to show that $\ker(X) = 16$. For this we use the octonionic presentation of $32$ from Example \ref{Example.6.12}. With this, and under the identification from Lemma \ref{Lemma.6.13} where $16 \simeq \mathbb{H}^{4}$, we need to show that $\ker(X) = \mathbb{H}^{4}$. Multiplying out the gamma matrices using \((82)\), we see:

$$X = e^2 \otimes J^2 L_{e_4} L_{e_5} - e^2 \otimes J^2 L_{e_6} L_{e_7} = -1 \otimes (L_{e_4} L_{e_5} - L_{e_6} L_{e_7}).$$

So, we must check that $L_{e_4} L_{e_5} = L_{e_6} L_{e_7}$ as linear transformations of $\mathbb{H}^{4}$.

Letting $i, j, k$ be the unit imaginary quaternions and $\ell$ any imaginary unit in $\mathcal{O}$ orthogonal to $\mathbb{H}$, according to \((A.6)\), we may choose $e_4 = \ell$, $e_5 = \ell i$, $e_6 = \ell j$ and $e_7 = \ell k$. Using the Cayley–Dickson relations \((73)\) we compute for any $\psi \in \mathbb{H}^{4}$ as follows:

$$X \psi = (-L_{e_4} L_{e_5} + L_{e_6} L_{e_7}) \psi = -\ell ((\ell i) \psi) + (\ell j)(\ell k) \psi = -\ell ((\ell i) \psi) + (\ell j)(\ell k) \ell^{-1} \psi = \ell ((\ell i) \psi) \ell^{-1} + (\ell j)(\ell k) \ell^{-1} = \psi i + j k \psi = \psi i - \psi i = 0$$

where in the third line we used \((74)\). \hfill \Box

Proposition 4.17 (6-brane locus fixed by $\text{Spin}(3)$). The super subspace $\mathbb{R}^{6,1} \rightarrow \mathbb{R}^{10,1} \rightarrow 32$ is fixed by every element in $\text{SU}(2)_{L}$.

Proof. By Lemma \ref{Lemma.4.16} every nontrivial element of $\text{Spin}(2)$ fixes the 6-brane. The copy of $\text{Spin}(2)$ that appears in the statement of Lemma \ref{Lemma.4.16} is the lift of $U(1) \subseteq \text{SU}(2) \subseteq \text{SO}(4)$ to $\text{Spin}(4)$, where $U(1)$ is included as the diagonal matrices

$$e^{it} \in U(1) \mapsto \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} \in \text{SU}(2).$$

Yet the proof of Lemma \ref{Lemma.4.16} applies equally well to any other choice of $U(1)$ subgroup of $\text{SU}(2)$ lifted to $\text{Spin}(4)$. Hence, it applies to all of $\text{SU}(2)$. \hfill \Box

This concludes our list of results expanding on the statement of Prop. \ref{Prop.4.15}

4.2 Non-simple singularities and Brane intersection laws

There is an evident concept of intersections of simple singularities in super spacetime (Def. \ref{Def.4.18} below) as well as of higher order intersections. This leads to a true of decreasing BPS degree. Here we discuss most of the intersections of two simple singularities (Prop. \ref{Prop.4.19} below). Higher order intersections may be discussed analogously. In the interpretation via the black brane scan (Sec. \ref{Sec.2.2}) these correspond to bound/intersecting black brane species.

Definition 4.18 (Intersection of simple singularities by Cartesian product group actions). Let $G_1$ and $G_2$ be two finite group actions (Example \ref{Example.3.48}) on $\mathbb{R}^{10,1} \rightarrow 32$ (Def. \ref{Def.3.37}), each corresponding to a simple singularity (Def. \ref{Def.4.1}), such that these actions commute with each other, hence such that the Cartesian product action $G_1 \times G_2$ exists. Then we say that the intersection of the simple singularity of $G_1$ with the simple singularity of $G_2$ is that corresponding to the product group action $G_1 \times G_2$. 

48
Proposition 4.19 (Non-simple real ADE-Singularities in 11d super-Minkowski spacetime). The non-simple singularities (Def. 4.1) in $D = 11$, $\mathcal{N} = 1$ super-Minkowski spacetime arising as intersections (Def. 4.18) of two simple singularities from Theorem 4.3 include those shown in the following table:

| Black brane species | BPS | Fixed locus in $\mathbb{R}^{10,1|32}$ | Type of singularity in $\mathbb{R}^{10,1}$ | Intersection law |
|---------------------|-----|-------------------------------------|-------------------------------------|------------------|
| M2 \( \sim \) MK6 | \(\frac{1}{4}\) | $\mathbb{R}^{2,1|4 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_2 \times \mathbb{Z}_2 \subset (\mathbb{Z}_2)^2$ |
| \(\frac{3}{16}\) or \(\frac{1}{4}\) | $\mathbb{R}^{2,1|6 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_n + 1$ |
| \(\frac{3}{16}\) or \(\frac{1}{4}\) | $\mathbb{R}^{2,1|6 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_n + 1$ |
| \(\frac{3}{16}\) or \(\frac{1}{4}\) | $\mathbb{R}^{2,1|6 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_n + 1$ |
| \(\frac{3}{16}\) or \(\frac{1}{4}\) | $\mathbb{R}^{2,1|6 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_n + 1$ |
| \(\frac{3}{16}\) or \(\frac{1}{4}\) | $\mathbb{R}^{2,1|6 \mathbb{Z}}$ | $\Delta$ | \(\mathbb{C}\) |
| \(\frac{1}{4}\) | $\mathbb{Z}_n + 1$ |

The cases M2 \(\sim\) MO9, M5, MW are \(\frac{1}{4}\) BPS when the M2-singularity is of type $\mathbb{Z}_2 \subset \mathbb{SU}(2)_L \times \mathbb{SU}(2)_R$, and \(\frac{3}{16}\) BPS when the M2-singularity is of type $\mathbb{Z}_{\geq 3} \subset \mathbb{SU}(2)_L \times \mathbb{SU}(2)_R$.

Proof. The existence is in each case given by checking that the two factors in the Cartesian product group $G_1 \times G_2$, that labels the singularity type, indeed have commuting actions on super spacetime. Apart from the immediate commutativity following from [45], this makes use of the fact that $(\mathbb{Z}_2)^2, L.R \subset \mathbb{SU}(2)^2\), is the inclusion of the group center.

What remains is to verify that the intersections have spinor reps/BPS-degree as shown, but this can be checked explicitly case by case. The case which we denote M2 \(\parallel\) MK6 also appears as [MedFig09], 7.2 and around (68)].
| Symbol | Equation | References |
|--------|----------|------------|
| MK6   | $(R^{10,1|32})^{(G_{ADE})R}$ | (2.6) |
| MO9   | $(R^{10,1|32})^{G_{HW}}$ | (2.2) |
| $\frac{1}{2}$ NS5$_L$ | MK6 $\dashv$ MO9$_L$ | (2.8) |
| $\frac{1}{2}$ NS5$_H$ | MK6 $\dashv$ MO9$_H$ | (2.8) |
| M2    | $(R^{10,1|32})^{(G_{ADE})\Delta}$ | (2.5) |
| MO9   | $(R^{10,1|32})^{G_{HW}}$ | (2.2) |
| NS1$_H$ | M2 $\dashv$ MO9$_H$ | (2.10) |
| E1    | M2 $\dashv$ MO9$_L$ | (2.10) |
| MK6   | $(R^{10,1|32})^{(G_{ADE})R}$ | (2.6) |
| M5    | $(R^{10,1|32})^{G_{W}}$ | (2.3) |
| M5$_{ADE}$ | M5 $\parallel$ MK6 | (2.10) |

**Figure 1.** Intersections of simple singularities in 11d super spacetime. Indicated on the main axes are simple singularities from Theorem 4.3. The intersections are shown according to Prop. 4.19.
Example 4.20 (M2 inside MK6). The example M2∥MK6 in Prop. 4.19 is implicitly considered in [MedFig09, Sec. 7.2 and around (68)], there viewed as a black M2 in an orbifold background. As in footnote 15 we may identify the orbifold away from the M2-orbifold singularity, which is \( \mathbb{R}^{10,1|32} \parallel \mathbb{Z}_2 \), as that of a black MK6 according to Theorem 4.3, hence the complete orbifold as the intersection of the two.

Notice how the group theory implies intersection laws:

Example 4.21 (M2 intersecting M5). In order to have an intersection of singularities (Def. 4.18), the corresponding group actions need to commute with each other, so that their product group action makes sense. For possible intersections of the black M2 with the black M5 as in Prop. 4.19, this means that the action of the diagonal subgroup in \( \mathbb{Z}_2 \) \times \( \mathbb{Z}_2 \) has to commute with the action of the diagonal subgroup action in SU(2) \times SU(2). But the first \( \mathbb{Z}_2 \) is in the center of the latter. Hence the condition is that \( \mathbb{Z}_2 \) commutes with the diagonal in SU(2) \times SU(2). The latter is generated from elements of the form \( \Gamma_{ab} + \Gamma_{cd} \) with indices ranging, say in \( \{2, \cdots, 9\} \). But \( \mathbb{Z}_2 \) is generated from a single \( \Gamma_e \). For that to commute with the others, we must have either \( e = 1 \) or \( e = 10 \). But this implies that the fixed spaces of the two actions do not contain each other, hence that the M2 intersects the M5 without being contained in it.
5 Real ADE-equivariant rational cohomotopy

Here we discuss certain group actions on the 4-sphere (Def. 5.1 below), as well as the resulting incarnation of the 4-sphere as an object in equivariant rational super homotopy theory (Def. 3.46). The motivation for the particular actions considered was explained in Remark 2.1 of Section 2.2. The main result of this section is the explicit system of minimal dgc-algebra models for this equivariant 4-sphere, this is Prop. 5.7 below.

By Example 3.33 and Example 3.47, taking this equivariant 4-sphere as the coefficient for a generalized cohomology theory (Def. A.24) defines real ADE-equivariant rational super cohomotopy in degree 4. We study this cohomology theory on super-spacetimes, below in Section 6.

5.1 Real ADE-actions on the 4-sphere

Following Remark 2.1, we consider the following group actions on the 4-sphere:

**Definition 5.1 (Actions on the 4-sphere).** We may regard the 4-sphere as the unit sphere in the direct sum of the real numbers $\mathbb{R}$ with the quaternions $\mathbb{H}$ (Example A.7):

$$S^4 \simeq S(\mathbb{R} \oplus \mathbb{R} \oplus \mathbb{R}^2 \oplus \mathbb{R}) \oplus \mathbb{H}. \quad (49)$$

This decomposition induces the following group actions (Def. 3.1) on the 4-sphere (we use the shorthand notation for actions from Remark 3.2):

(i) Multiplication on the left and right by unit quaternions in $\mathbb{H}$ preserves the 4-sphere, giving two actions of $\text{SU}(2)$, which we denote by $\text{SU}(2)_L$ and $\text{SU}(2)_R$, respectively.

(ii) These two actions manifestly commute with each other, and hence we have the corresponding action of the Cartesian product of $\text{SU}(2)$ with itself, which we denote by $\text{SU}(2)_L \times \text{SU}(2)_R$.

(iii) We denote the action induced from this via the diagonal homomorphism $\text{SU}(2) \hookrightarrow \text{SU}(2) \times \text{SU}(2)$ by $\text{SU}(2)_\Delta$. This factors (via (79)) through the action induced by the canonical action of $\text{SO}(3)$ on $\text{Im}(\mathbb{H}) \simeq \mathbb{R}^3$.

(iv) There is then an inclusion $S^1 \hookrightarrow \text{SU}(2)$ such that the corresponding restriction of the diagonal action fixes the second coordinate in (49). This induced action we accordingly denote by $S^1_\Delta$.

(v) The $\mathbb{Z}_2$-action induced by the involution (Example 3.3) given by reflection of the last coordinate in (49) (i.e. multiplication by -1 on the real part of the quaternionic coordinate in (49)) we denote by $(\mathbb{Z}_2)_{\text{HW}}$.

(vi) This commutes with the $\text{SU}(2)_\Delta$-action, so that there is the corresponding action of the Cartesian product group, which we accordingly denote by $\text{SU}(2)_\Delta \times (\mathbb{Z}_2)_{\text{HW}}$.

**Remark 5.2 (Summary of actions).** With the evident shorthand notation, the action on the 4-sphere, from Def. 5.1 are given, in terms of the decomposition (49), as follows:

$$S^4 \simeq S(\mathbb{R} \oplus \mathbb{R} \oplus \mathbb{R}^2 \oplus \mathbb{R}) \oplus \mathbb{H} \oplus \text{SU}(2)_L \oplus \text{SU}(2)_R \oplus (\mathbb{Z}_2)_{\text{HW}} \quad (50)$$

which may be collected into two actions of Cartesian products as

$$\begin{align*}
\text{SU}(2)_L \times \text{SU}(2)_R \\
\text{SU}(2)_\Delta \times (\mathbb{Z}_2)_{\text{HW}}
\end{align*}$$

and

$$S^4 \quad S^4.$$
Example 5.3 (Suspended Hopf action). Under the canonical inclusion $S^1 \simeq U(1) \hookrightarrow SU(2)_L$ of the circle group into the special unitary group (as the subgroup of diagonal matrices) the induced action $S^1$ on the 4-sphere, by Def. 5.1 is the image under topological suspension of the $S^1$-action that exhibits the complex Hopf fibration $S^3 \to S^2$ (Def. A.10) as an $S^1$-principal bundle.

5.2 Systems of fixed loci of the 4-Sphere

Lemma 5.4 (The systems of real ADE-fixed points of the 4-sphere). Let $G_{\text{ADE}} \subset SU(2)$ be a finite subgroup of $SU(2)$ (Remark A.9) and write $(G_{\text{ADE}})_{L,R,\Delta}$ for its various actions on the 4-sphere, via Def. 5.1. The following displays the the systems of fixed point spaces of $S^4$ (according to Example 3.22) for the two actions of product groups from Def. 5.1 Here we let $G \subset G_{\text{ADE}}$ denote any non-cyclic subgroup. If there is none such, the corresponding entries of the diagrams do not appear.

(i) For the action $SU(2)_\Delta \times (\mathbb{Z}_2)_{\text{HW}}$ in Def. 5.1 the system of fixed points

$$(S^4)^{(-)} : \text{Orb}^{\text{op}}_{(G_{\text{ADE}})_\Delta \times (\mathbb{Z}_2)_{\text{HW}}} \to \text{Spaces}$$

is, in part, as follows:

(ii) For the action $SU(2)_L \times SU(2)_R$ in Def. 5.1 the system of fixed points

$$(S^4)^{(-)} : \text{Orb}^{\text{op}}_{(G_{\text{ADE}})_L \times (G_{\text{ADE}})_L} \to \text{Spaces}$$

is, in part, as follows:
Proof. This follows directly by careful inspection, manifestly so using the arrangement of the actions in (50).

To first approximation, and for the purposes of the present article, we will be interested in the system of fixed point spaces from Lemma 5.4 only rationally (Def. A.18). Hence in the remainder of this section we work out an explicit model for the corresponding image of the 4-sphere in equivariant rational homotopy theory (Example 42) and hence, via Example 3.47, in equivariant rational super homotopy theory (Def. 3.46). The result is Prop. 5.7 below.

**Lemma 5.5** (Rational image of real ADE-actions on the 4-sphere).

(i) For each element $g \in SU(2)_{L,R,\Delta}$ the corresponding action on the 4-sphere, via Def. 5.1 is an orientation preserving isometry (of the round 4-sphere) while the nontrivial element $\sigma \in (\mathbb{Z}_2)_{HW}$ acts as an orientation-reversing isometry.

(ii) It follows that the DGC-algebra homomorphism corresponding to $\rho(g)$ after passing to the minimal Sullivan model of the $n$-spheres (Example A.21) is the identity for all $g \in G_{ADE}$, while the DGC-algebra homomorphism corresponding to $\rho(\sigma)$ acts as minus the identity on $\omega_4$ and as the identity on $\omega_7$:

$$
\begin{array}{|c|c|}
\hline
\omega & g \in G_{ADE} \\
\hline
\omega_4 & \rho(g)^*(\omega) \\
\hline
\omega_7 & \rho(g)^*(\omega) \\
\hline
\end{array}
$$

Proof. The orientation preserving isometries of $S^4$ form the group SO(5), acting on $S^4 \simeq S(\mathbb{R}^5)$ via its canonical action on $\mathbb{R}^5$. Now by Def. 5.1 and using (78) it follows that the $\rho(g)$ acts through the subgroup $SO(4) \hookrightarrow SO(5)$, and hence itself as an orientation-preserving isometry.

This means that under pullback of differential forms along $\rho(g)$, the canonical volume form of $S^4$ is sent to itself. But under passing to minimal Sullivan models in Example A.21 this volume form is identified with the generator $\omega_4 \in CE(l(S^4))$. Hence

$$
\rho(g)^*(\omega_4) = \omega_4.
$$

With this, respect for the CE-differential implies that also $\rho(g)^*(\omega_7) = \omega_7$, since this is the only primitive for $-\frac{1}{2}\omega_4 \wedge \omega_4$ in $CE(l(S^4))$, according to (90):

$$
\begin{array}{ccc}
\rho(g)^*(\omega_7) & \xleftarrow{\rho(g)^*} & \omega_7 \\
\downarrow & & \downarrow \\
-\frac{1}{2}\omega_4 \wedge \omega_4 & \xleftarrow{\rho(g)^*} & -\frac{1}{2}\omega_4 \wedge \omega_4.
\end{array}
$$

**Remark 5.6** (Equivariant rational homotopy improving on plain rational homotopy). Lemma 5.5 implies that the ADE-actions on the 4-sphere are invisible to plain rational homotopy theory (Def. A.18). But equivariant rational homotopy theory (Example 3.45) and hence equivariant rational super homotopy theory (Def. 3.46) is more fine-grained and does recognize that the ADE-action on the 4-sphere is not in fact trivial, by remembering its fixed point loci. This is made explicit by Lemma 5.7.
Proposition 5.7 (System of dgc-algebra models for fixed points real ADE-action on the 4-Sphere). Under passage to minimal dgc-algebra models CE(\{(S^n)\}) for the n-spheres (Example A.21), the systems of fixed points of the real ADE-actions on the 4-sphere, from Lemma 5.4, becomes the following:

(i) For the \((G_{ADE})_{\Delta} \times (\mathbb{Z}_2)_{GW}\)-action the system of minimal dgc-algebras

\[
\text{CE}\left(\left\{(S^4)\right\}\right): \text{Orb}_{(G_{ADE})_{\Delta} \times (\mathbb{Z}_2)_{GW}} \rightarrow \text{dgcAlg}
\]

is, in the parts corresponding to those shown in Lemma 5.4:

(ii) For the \((G_{ADE})_L \times (G_{ADE})_R\)-action, the system of minimal dgc-algebras

\[
\text{CE}\left(\left\{(S^4)\right\}\right): \text{Orb}_{(G_{ADE})_L \times (G_{ADE})_R} \rightarrow \text{dgcAlg}
\]

is, in the parts corresponding to those shown in Lemma 5.4, given by
Proof. In both cases the vertical maps at the top are obtained by using Lemma 5.5 in Lemma 5.4. That all the other maps appearing in Lemma 5.4 are represented by zero-maps on the minimal dgc-algebra models reflects the basic fact that every map from a sphere of lower dimension into one of higher dimensions is null homotopic.

Prop. 5.7 serves to determine the explicit coefficients of real ADE-equivariant rational cohomotopy in degree 4. We will make repeated use of this in the proofs in Section 6.
6 Real ADE-equivariant brane cocycles

In the previous two subsections we have discussed real ADE-actions both on $\mathbb{R}^{10,1|32}$ (Sec. 4) and on $S^4$ (Sec. 5). This now allows to discuss the possible equivariant enhancements (Example 3.49) of the M2/M5-brane cocycle (Prop. 3.43) that are compatible with these actions.

**Theorem 6.1** (Equivariant enhancements of the fundamental brane cocycles). *With respect to the real ADE-actions [45] on $D = 11$, $N = 1$ super spacetime from Theorem 4.4 and the real ADE-actions [50] on the 4-sphere from Def. 5.7, we have non-trivial cocycles in real ADE-equivariant rational cohomotopy of superspaces as shown in Table 3 providing equivariant enhancement (Example 3.49) of the fundamental M2/M5-cocycle (Prop. 3.43) as well as of the zero-cocycle on super spacetime.*

**Proof.** We need to produce data as discussed in Example 3.49. First of all this means to check that the fundamental brane cocycles at each stage (from Example 3.40 and Prop. 3.43) are plain equivariant in the first place, hence that, in the notation of Remark 3.8 we have

$$\begin{array}{ccc}
G_{\mathbb{R}^{10,1|32}} & \xrightarrow{\mu_{M2/M5}} & G_{S^4}, \\
\bigcup & & \\
\bigcup & & \\
G/G & \xrightarrow{\eta} & G_{(S^4)^G}.
\end{array}$$

We check this in Prop. 6.3, Prop. 6.5 and Prop. 6.6 below.

Now first consider the case of simple singularities (Def. 4.1), where the system of fixed loci in superspace-time is constant away from the trivial subgroup (Example 4.2). By Prop. 5.7, in these cases also the system of coefficients for real ADE-equivariant rational cohomotopy is constant away from the trivial subgroup; and hence a cocycle is entirely determined by the single component corresponding to unique morphism between the two extreme cases of $G$-orbits:

$$\begin{array}{ccc}
G & \xrightarrow{\mu_{(e)}} & G
\end{array}$$

Prop. 6.11 and Example 6.12 below establish the possible data describing such diagrams. In particular, it shows that the choice of homotopy $\eta$ may depend in each case only on the bosonic fixed locus. This means that all cocycles on simple singularities are fixed by their component [53].

Analogously, for non-simple singularities (Def. 4.1) a cocycle involves this kind of data at each orbit type where the bosonic singular locus changes (see again Example 4.2). For intersections of two simple singularities (Def. 4.18) this means that the cocycle is now determined by its components on four morphisms in the orbit category, as shown here:

The data assigned to each square is determined by Example 6.12 which shows that the pasting composition of the consecutive homotopies shown vanishes, so that the 2-commutativity of the diagram is implied. □
| Black brane species \ Type of singularity in $\mathbb{R}^{10,1}$ | Systems of fundamental brane species at singular loci |
|---------------------------------------------------------------|--------------------------------------------------|
| M2 $(G_{ADE})_\Delta$                                        | ST $\mathbb{R}^{1,1}_{16} \times G_W$ $S^4$    |
| M5 $(Z_2)_W$                                                 | ST $\mathbb{R}^{10,1}_{32} \times G_W$ $S^4$ |
| MO9 $(Z_2)_{HW}$                                             | MO9 $\mathbb{R}^{9,1}_{16} \times G_W$ $S^3$ |
| MW $(Z_2)_{MW}$                                              | MW $\mathbb{R}^{10,1}_{32} \times G_W$ $S^4$ |
| MK6 $(G_{ADE})_R$                                            | MK6 $\mathbb{R}^{6,1}_{16}$ $S^0$               |
| $M_2 \vdash M_5$                                             | $M_1$                                            |
| $(Z_{n+1})_\Delta \times (Z_2)_W$                           | ST $\mathbb{R}^{10,1}_{32} \times G_W$ $S^4$ |
| $M_2 \vdash MO9$                                             | ST $\mathbb{R}^{9,1}_{16} \times G_W$ $S^3$ |
| $(Z_{n+1})_\Delta \times (Z_2)_{HW}$                         | ST $\mathbb{R}^{10,1}_{32} \times G_W$ $S^4$ |

Table 3. Cocycles in equivariant rational cohomotopy of $D = 11$, $N = 1$ super spacetime, according to Theorem 6.1. The singularities (black branes) are from Thm. 4.3, Prop. 4.19; the component cocycles $\mu_\nu$ (fundamental branes) from the old brane scan (Prop. 3.39); the homotopies $\text{svol}_\nu$ are their Green–Schwarz action functionals (Prop. 6.11).
6.1 Plain equivariance of the fundamental brane cocycles

Part of the data of an equivariant enhancement of a supercocycle is the property that the cocycle map be plain equivariant, hence intertwines the group actions on both sides. Here we check that this is the case for the cocycles appearing in Theorem 6.1.

Lemma 6.2 (Real ADE-action on M-brane super-cocycles). With respect to the actions from Theorem 4.3, the M2-cocycle (Def. 3.42) is invariant under all $g \in G_{\text{ADE}}$ and changes sign under the non-trivial element $\sigma \in G_{\text{W}}$, while the M5-cochain is invariant under both:

\[ \begin{array}{c|c|c} \mu & g \in G_{\text{ADE}} & e \neq \sigma \in G_{\text{W}} \\\\ \hline \mu_{M2} & \mu_{M2} & -\mu_{M2} \\\\ \mu_{M5} & \mu_{M5} & \mu_{M5} \end{array} \]  

(54)

Proof. The following is the argument using the Dirac representation (Prop. A.3). For the reflection operation we have from (72) that

\[ \rho(\sigma)^*(\psi) = i\Gamma_{10}\psi, \quad \rho(\sigma)^*(e^a) = \begin{cases} e^a & \text{if } a \neq 10, \\ -e^a & \text{otherwise.} \end{cases} \]

Extending this to an algebra homomorphism, this yields:

\[
\rho(\sigma)^*(\mu_{M2}) = \rho(\sigma)^*\left(\frac{i}{2}\Gamma_{10}\Gamma_{a_1a_2}\psi \wedge e^{a_1} \wedge e^{a_2}\right)
= \frac{i}{2} \sum_{a_1,a_2 \neq 10} (\Gamma_{10}\psi)\Gamma_{a_1a_2}(\Gamma_{10}\psi) \wedge e^{a_1} \wedge e^{a_2} + \ldots
= \frac{i}{2} \sum_{a_1,a_2 \neq 10} \psi\Gamma_{a_1a_2}\Gamma_{10}\psi \wedge e^{a_1} \wedge e^{a_2} + \ldots
= (-1)^{\frac{i}{2}} \sum_{a_1,a_2 \neq 10} \psi\Gamma_{a_1a_2}\Gamma_{10}\psi \wedge e^{a_1} \wedge e^{a_2} + \ldots
= -\mu_{M2}.
\]

(55)

Here the first three equalities just spell out the definition. In the second line we decomposed the sum over indices into summands that involve the 10th index and those that do not. We display only the first, as the argument for the second is the same except for two extra signs that appear, and hence cancel.

Under the brace in the third line we use (67) and then in the next line we commute $(-\Gamma_{10})$ past $\Gamma_0\Gamma_{a_1}\Gamma_{a_2}$, which picks up a total minus sign due to (67) and since $a_1, a_2 \neq 10$ in this first summand, by construction. Finally we cancel the product of $-\Gamma_{10}$ with $\Gamma_{10}$, using again (67). In total this leaves an overall sign.

Since $g \in G_{\text{ADE}}$ acts by an even number of such spatial reflections, this also implies $\rho(\sigma)^*(\mu_{M2}) = \mu_{M2}$.

Finally, from this the statements for $\mu_{M5}$ follows by the property of respecting the CE-differential, as in (52).

\[ \square \]

Proposition 6.3 (Real ADE-equivariance of the joint M2/M5-brane super-cocycle). The combined M2/M5 cocycle $\mathbb{R}^{10,1|32} \overset{\mu_{M2/M5}}{\longrightarrow} S^4$ (Prop. 3.43) is equivariant with respect to the real ADE-actions (45) (on $\mathbb{R}^{10,1|32}$ from Theorem 4.3 and the real ADE actions (50) on $S^4$ from Def. 5.1). In the notation of Remark 3.8 this means that

\[
\begin{array}{cccccc}
G_{\text{ADE}} & \mathbb{R}^{10,1|32} & G_{\text{ADE}} & \mathbb{R}^{10,1|32} & G_{\text{ADE},\text{HW}} & \mathbb{R}^{10,1|32} & G_{\text{ADE},\text{HW}} \\
\mu_{M2/M5} & \overset{\gamma}{\longrightarrow} & \mu_{M2/M5} & \overset{\gamma}{\longrightarrow} & \mu_{M2/M5} & \overset{\gamma}{\longrightarrow} & \mu_{M2/M5}
\end{array}
\]

\[ \overset{\gamma}{\longrightarrow} S^4, \quad \overset{\gamma}{\longrightarrow} S^4, \quad \text{and} \quad \overset{\gamma}{\longrightarrow} \mathcal{I}(S^4). \]

59
Proof. This follows by the combination of Lemma 5.5 with Lemma 6.2. Under the map (38), the table of transformation properties of generators of $S^4$ turns into the table of transformation properties of the M-brane super-cochains.

Proposition 6.4 (M2-cocycle vanishes on MW, M5 and MO9). The restriction of the M2-brane cocycle $\mu_{M2} \in \text{CE}(\mathbb{R}^{10,1\vert 32})$ along the inclusion $\mathbb{R}^{p,1\vert N} \hookrightarrow \mathbb{R}^{10,1\vert 32}$ of the MW, M5, and MO9 fixed subspace from Prop. 4.7 vanishes identically:

$$\mu_{M2}\big|_{\mathbb{R}^{p,1\vert N}} = 0.$$ 

Proof. By Lemma 6.2, the M2-cocycle changes sign under the corresponding p-brane involutions. Hence it has to vanish on the fixed space of these involutions.

For illustration, we now spell this out in more detail for the case of the MO9: without loss of generality, we may take the MO9 to be at $x_{10} = 0$ (by Lemma 4.9). Consider then the corresponding decomposition of the M2-cocycle in the form into

$$\mu_{M2} = \left( i \sum_{a \leq 9} \overline{\psi} \Gamma_{a10} \psi \wedge e^a \right) \wedge e^{10} + \frac{i}{2} \sum_{a_1,a_2 \leq 9} \overline{\psi} \Gamma_{a_1 a_2} \psi \wedge e^{a_1} e^{a_2}.$$ 

The restriction of the first summand to $\mathbb{R}^{9,1\vert 16}$ vanishes simply because $e^{10}$ vanishes on the underlying $\mathbb{R}^{9,1}$. On the other hand, the restriction of the second summand to $\mathbb{R}^{9,1\vert 16}$ vanishes because its fermionic factor vanishes after restriction to 16.

By the proof of Lemma 4.8, 16 is the +1 eigenspace of $\Gamma_{10}$ in 32. Hence with $\Gamma_{10} \psi = \psi$ we find that $\mu_{D2}\big|_{\mathbb{R}^{9,1\vert 16}}$ is equal to minus itself:

$$\mu_{D2}\big|_{\mathbb{R}^{9,1\vert 16}} = \frac{i}{2} \sum_{a_1,a_2 \leq 9} \overline{\psi} \Gamma_{0} \Gamma_{a_1} \Gamma_{a_2} \psi \wedge e^{a_1} \wedge e^{a_2} = \frac{i}{2} \sum_{a_1,a_2 \leq 9} \psi \Gamma_{0} \Gamma_{a_1} \Gamma_{a_2} \Gamma_{10} \psi \wedge e^{a_1} \wedge e^{a_2} = -\mu_{D2}\big|_{\mathbb{R}^{9,1\vert 16}}.$$ 

Here we spelled out the Dirac conjugate (69) and then picked up a minus sign from commuting $\Gamma_{10}$ with $\Gamma_{0} \Gamma_{a_1} \Gamma_{a_2}$.

Similarly we have the following:

Proposition 6.5 (ADE-equivariance of the heterotic F1 super-cocycle). The heterotic/type I string cocycle from Example 3.40 is equivariant with respect to the residual $(\mathbb{Z}_{n+1})_{\Delta}$-actions (45) (on $\mathbb{R}^{9,1\vert 16}$ from Theorem 4.3 and (50) on $S^3 = (S^4)^{G_{HW}}$ from Def. 5.1. In the notation of Remark 3.8 this means that

$$\mathbb{R}^{9,1\vert 16} \xrightarrow{\mu_{F1}/I} (\mathbb{Z}_{n+1})_{\Delta} \xrightarrow{\text{orientation-preserving}} S^3.$$ 

Proof. The action on $S^3$ is through SO(3) and hence manifestly an orientation-preserving isometry. Therefore the same kind of argument as in the proof of Lemma 5.5 shows that the action on the minimal dgc-model for $S^3$ is trivial. By Example 3.10 this means that equivariance in this case means that the cocycle is in fact invariant under the action on spacetime. Indeed, since the spacetime action $(\mathbb{Z}_{n+1})_{\Delta}$ is orientation preserving, it factors through the canonical Spin(10,1)-action, and under this the cocycle is invariant, by its very origin from the old brane scan, Prop. 3.39. 

\[\Box\]
Proposition 6.6 (Reality of the F1 super-cocycle on the M2-brane). The fundamental string cocycle in \( D = 3 \) from Example 3.46 is equivariant with respect to the residual \( G_{\text{HW}} \)-actions \((45)\) on \( \mathbb{R}^{2,1|16} \) from Theorem 4.3 and \((50)\) on \( S^2 = (S^4)^{(2n+1)\Delta} \) from Def. 5.1. In the notation of Remark 6.7 this means that

\[
\begin{array}{ccc}
G_{\text{HW}} & \xrightarrow{\mu_{F1}^{D=3}} & G_{\text{HW}} \\
\mathbb{R}^{2,1|2} & \xrightarrow{} & S^2
\end{array}
\]

Proof. The same kind of computation as in \((55)\) shows that \( \mu_{F1}^{D=3} \) is invariant under \( G_{\text{HW}} \).

Moreover, the same kind of argument as in Lemma 5.5 leading to \((56)\) shows that the rational generators of the 2-sphere from Lemma A.21 transform as

| \( g \in G_{\text{ADE}} \) | \( c \neq \sigma \in G_{\text{HW}} \) |
|---|---|
| \( \omega \) | \( \rho(g)^*(\omega) \) | \( \rho(\sigma)^*(\omega) \) |
| \( \omega_2 \) | \( \omega_2 \) | \( -\omega_2 \) |
| \( \omega_3 \) | \( \omega_3 \) | \( \omega_3 \) |

Hence, as opposed to the degree-2 generator \( \omega_2 \), the degree-3 generator \( \omega_3 \) is invariant, too, and the claim follows.

This concludes our discussion of the plain real ADE-equivariance of the fundamental brane cocycles, under the various action appearing in Theorem 6.1. This is the extra property that an equivariant enhancement has to satisfy. Now we turn to the extra structure that equivariant enhancement involves (the “extra degrees of freedom”).

6.2 Components of equivariant enhancement: The GS-action functional

Here we work out the component data of equivariant enhancements of super-cocycles (Example 3.49) of relevance in Theorem 6.1, that is associated with morphisms in the orbit category (Def. 3.20) along which the bosonic dimension of the fixed locus in super-spacetime decreases (see Example 4.2). The main result of this section is Prop. 6.11 below, which says, in the terminology of Sec. 2, that this data is given by fundamental brane cocycles trivializing over their own black brane incarnation via their Green–Schwarz action functional. We conclude this section in Example 6.12 by explaining how this is used in the proof of Theorem 6.1.

Remark 6.7 (Left-invariant differential forms on the super Minkowski super Lie group). If we regard a super Minkowski spacetime \( \mathbb{R}^{p,1|N} \) (Def. 3.36) as a super Lie algebra, via Example 3.34 we can exponentiate this super Lie algebra to obtain a simply-connected super Lie group. It turns out that the underlying super manifold of this group is just \( \mathbb{R}^{p,1|N} \), so we abuse notation by denoting the algebra and group by the same symbol.

This super manifold comes with canonical coordinate functions

\[
\{x^a\}_{a=0}^p , \quad \{\theta^a\}_{a=1}^N
\]

as well as their de Rham differentials

\[
\{d_{\text{dR}}x^a\}_{a=0}^p , \quad \{d_{\text{dR}}\theta^a\}_{a=1}^N
\]

But the non-triviality of the super Lie bracket implies that, unlike ordinary (bosonic) Minkowski spacetime, the differential forms \( d_{\text{dR}}x^a \) are not left-invariant (nor right-invariant) under the left or right action of the super Lie group on itself. In physics jargon, we say they are not supersymmetric. Instead, a basis of
left-invariant (hence supersymmetric) differential 1-forms on the super Minkowski super Lie group is given by
\[
e^a := d_{\text{dR}} x^a + \bar{\theta} \Gamma^a d_{\text{dR}} \theta, \\
\psi^a := d_{\text{dR}} \theta^a.
\] (57)

Of course the Chevalley-Eilenberg algebra of a super Lie group is isomorphic to the sub dge-algebra of its de Rham algebra on the left-invariant differential forms, and under this correspondence (57) readily yields (33).

**Definition 6.8 (Supersymmetric volume form).** Let \( \mathbb{R}^{p,1|\mathbb{N}} \) be a super Minkowski spacetime (Def. 3.36). Then the *supersymmetric volume form* on \( \mathbb{R}^{p,1|\mathbb{N}} \) is defined by
\[
\text{svol}_{p+1} := e^0 \wedge e^1 \wedge \cdots \wedge e^p \in \text{CE}(\mathbb{R}^{p,1|\mathbb{N}}).
\]

Via remark 6.7 this may equivalently be expressed in terms of plain differential forms on the super Minkowski supermanifold as
\[
\text{svol}_{p+1} = \frac{1}{(p+1)!} \left( \frac{d_{\text{dR}} x^0 \wedge d_{\text{dR}} x^1 \wedge \cdots \wedge d_{\text{dR}} x^p}{\text{vol}_{p+1}} + (\bar{\theta} \Gamma^a d_{\text{dR}} \theta) \wedge (\cdots) \right),
\] (58)

where the first summand is the ordinary (bosonic) volume form, while the second summand is a fermionic correction that makes the sum be left-invariant (hence supersymmetric).

**Lemma 6.9 (Supersymmetric volume form on black p-brane trivializes fundamental p-brane cocycle).** Let \( \mathbb{R}^{p,1|\mathbb{N}} \hookrightarrow \mathbb{R}^{10,1|\mathbb{32}} \) be one of the fixed point BPS subspaces (Def. 3.38) in the classification from Theorem 4.3. Then \( \pm 1 \) times the supersymmetric form on \( \mathbb{R}^{p,1|\mathbb{N}} \) (Def. 6.8) provides a trivialization for the p-brane cocycle on \( \mathbb{R}^{p,1|\mathbb{N}} \), in that
\[
d(\text{svol}_{p+1}) = \pm \frac{1}{p!} \left( \psi \Gamma_{a_1 \cdots a_p} \psi \right) \wedge e^{a_1} \wedge \cdots \wedge e^{a_p} \in \text{CE}(\mathbb{R}^{p,1|\mathbb{N}}).
\]

**Proof.** Since the fixed superspaces \( \mathbb{R}^{p,1|\mathbb{N}} \) in the classification of Theorem 4.3 are in particular fixed by the corresponding p-brane involution (Def. 4.4) the proof of Lemma 4.8 shows that the restriction of the complementary product of Clifford generators to the fixed Spin sub-representation \( \mathbb{N} \hookrightarrow \mathbb{32} \) is the identity, possibly up to a sign: \( \Gamma_{p+1} \Gamma_{p+2} \cdots \Gamma_{10}|_{\mathbb{N}} = \pm 1 \). But also \( \Gamma_0 \Gamma_1 \cdots \Gamma_{10} = \pm 1 \), since \( \mathbb{32} \) is chiral. Together this implies that \( \Gamma_0 \Gamma_1 \cdots \Gamma_{p}|_{\mathbb{N}} = \pm 1 \) and hence that
\[
\Gamma_{a_0}|_{\mathbb{N}} = \pm \frac{1}{p!} \epsilon_{a_0 a_1 \cdots a_p} \Gamma^{a_1 \cdots a_p}
\] (59)

with the same sign \( \pm \) for all \( 0 \leq a_0 \leq p \). Using this we compute as follows:
\[
d(\text{svol}_{p+1}) = \frac{1}{(p+1)!} \epsilon_{a_0 \cdots a_p} d (e^{a_0} \wedge \cdots \wedge e^{a_p}) \\
\propto \frac{1}{p!} \epsilon_{a_0 a_1 \cdots a_p} \left( \psi \Gamma^{a_0} \psi \right) \wedge e^{a_1} \wedge \cdots \wedge e^{a_p} \\
\propto \pm \frac{1}{p!^2} \epsilon_{a_0 a_1 \cdots a_p} e^{a_0 b_1 \cdots b_p} \left( \psi \Gamma_{b_1 \cdots b_p} \psi \right) \wedge e^{a_1} \wedge \cdots \wedge e^{a_p} \\
= \delta_{a_1 \cdots a_p} \\
\propto \pm \frac{1}{p!} \left( \psi \Gamma_{a_1 \cdots a_p} \psi \right) \wedge e^{a_1} \wedge \cdots \wedge e^{a_p}.
\]

Here the first step is just a combinatorial rewriting of the supersymmetric volume form, the second step collects the results of applying the CE-differential (33) via its derivation property, the third step uses (59) and in the fourth step we used the combinatorics of the skew-symmetrized Kronecker symbol. The omitted proportionality factors in each step are just integer powers of \( i \) that are fixed by spinor conventions and using that the result must be real.

\( \square \)
Proposition 6.10 (Super volume form is Green–Schwarz Lagrangian on super embedding). Let
\[ \mathbb{R}^{p,1|N} \hookrightarrow \mathbb{R}^{10,1|32} \]  
be one of the fixed point BPS subspaces (Def. 3.38) in the classification from Theorem 4.3. Then its supersymmetric volume form (Def. 6.8) is the restriction of the Green–Schwarz-type Lagrangian for a super \( p \)-brane along the embedding (60):
\[ \text{svol}_{p+1} = L_{GS,p+1}|_{\mathbb{R}^{p,1|N}}. \]  

Proof. For any embedding (60), the decomposition (58) says that svol\(_{p+1}\) is the sum
\[ \text{svol}_{p+1} = L_{NG,p+1}|_{\mathbb{R}^{p,1|N}} + \Theta_{p+1} \]
of the restriction of the Nambu-Goto Lagrangian \( L_{NG,p+1} \), which is the plain bosonic volume form
\[ \text{vol}_{p+1} = L_{NG}|_{\mathbb{R}^{p,1|N}}; \]
with a fermionic term \( \Theta_{p+1} \). But if the embedding is moreover that of a BPS fixed locus from Theorem 4.3, then, since \( d(\text{vol}_{p+1}) = 0 \) (by Remark 6.7), Lemma 6.9 says that \( \Theta_{p+1} \) is a fermionic potential for the \( p \)-brane cocycle:
\[ d\Theta_{p+1} = \mu_p \propto \frac{1}{p!} \left( \bar{\psi} \Gamma_{a_1 \cdots a_p} \psi \right) \wedge \epsilon^{a_1} \wedge \cdots \wedge \epsilon^{a_p}, \]
hence it is a WZW-term for this cocycle. Now the Green–Schwarz action functional comes from a very particular choice of such potential, but (59) implies that this is precisely the choice provided here by the supersymmetric volume form. We make this explicit for \( p = 2 \), the other cases work analogously:
\[ \Theta_{2+1} := \text{svol}_{2+1} - \text{vol}_{2+1} \]
\[ = \frac{1}{3!} \epsilon_{a_0 a_1 a_2} (dx^{a_0} + \bar{\theta} \Gamma^{a_0} d\theta) \wedge (dx^{a_1} + \bar{\theta} \Gamma^{a_1} d\theta) \wedge (dx^{a_2} + \bar{\theta} \Gamma^{a_2} d\theta) - dx^0 \wedge dx^1 \wedge dx^2 \]
\[ = \frac{1}{3!} \epsilon_{a_0 a_1 a_2} (\bar{\theta} \Gamma^{a_0} d\theta) (3dx^{a_1} \wedge (dx^{a_2} + \bar{\theta} \Gamma^{a_2} d\theta) + (\bar{\theta} \Gamma^{a_1} d\theta) \wedge (\bar{\theta} \Gamma^{a_2} d\theta)) \]
\[ = (\bar{\theta} \Gamma_{a_1 a_2} d\theta) \left( \frac{1}{2} dx^{a_1} \wedge (dx^{a_2} + \bar{\theta} \Gamma^{a_2} d\theta) + \frac{1}{6} (\bar{\theta} \Gamma^{a_1} d\theta) \wedge (\bar{\theta} \Gamma^{a_2} d\theta) \right), \]
where under the brace we used (59). This is indeed the form of the Green–Schwarz-WZW type Lagrangian term in the sigma model for the super 2-brane [DHN88, (2.1)] [DNP03, (3)]. The only difference is that here the bosonic indices range only as \( a_i \in \{0, 1, 2\} \) instead of \( a_i \in \{0, \cdots, 10\} \), and the fermionic coordinates range only over 16 inside 32. But this means exactly that we have the restriction of the full Green–Schwarz-WZW term along the embedding (61), as claimed. \( \square \)

Proposition 6.11 (Fundamental brane cocycles on their black brane cobounded by Green–Schwarz action). (i) Let \( \mathbb{R}^{p,1|N} \hookrightarrow \mathbb{R}^{10,1|32} \) be one of the fixed point BPS subspaces (Def. 3.38) in the classification from Theorem 4.3 with \( p \leq 5 \), hence the MW, or M2 or M5. Then the restriction of the M2/M5-brane cocycle (Prop. 3.43) to this subspace is homotopic to the trivial cocycle, and the homotopy is given by the corresponding Green–Schwarz action functional, according to Prop. 60.

\[ \mathbb{R}^{10,1|32} \xrightarrow{\mu_{M2/M5}} S^4 \]
\[ \mathbb{R}^{p,1|16} \xrightarrow{\text{svol}_{p+1}} S^4 \]

On the other hand, for the cases with \( p \geq 6 \) in the classification from Theorem 4.3, no such trivializing homotopy exists.
Let \( \mathbb{R}^{1,1|8} \hookrightarrow \mathbb{R}^{0,1,1|16} \) the relative fixed locus inclusion corresponding to the item \( \text{NS}_{1H} \) in Prop. 4.19. Then the restriction of the fundamental heterotic string cocycle (Example 3.40) along that inclusion has a trivializing homotopy given by its Green–Schwarz action functional, according to Prop. 60.

\[
\begin{array}{c}
\mathbb{R}^{0,1,1|16} \xrightarrow{\mu^\text{het}_{F_1}} S^3 \\
\mathbb{R}^{1,1|8} \end{array}
\]

\[\uparrow \quad \uparrow \quad \uparrow \]
\[\uparrow \quad \uparrow \quad \uparrow \]
\[\downarrow \downarrow \downarrow \]
\[\downarrow \downarrow \downarrow \]
\[\mu' \] \[\text{svol}_{1+1} \]

Proof. First observe the existence of trivializing coboundaries, as claimed:

- For \( p = 1 \) both the restrictions of \( \mu_{M2} \) and \( \mu_{M5} \) vanish identically, for degree reasons, while the restriction of \( \mu_{F_1} \) is trivialized by the super volume form according to Lemma 6.9.
- For \( p = 2 \) the cochain \( \mu_{M5} \) still vanishes identically by degree reasons, while \( \mu_{M2} \) has a coboundary, given by the volume form, according to Lemma 6.9.
- For \( p = 5 \), the cochain \( \mu_{M2} \) vanishes by Prop. 6.4, while now \( \mu_{M5} \) has a coboundary, again by Lemma 6.9.

By Example A.23 these coboundaries yield the required homotopy. This concludes the cases where the trivializing homotopy does exist.

We now turn to the cases where it does not exist:

- For restriction to \( p = 6 \) the M2-cocycle remains non-trivial, by the old brane scan (Prop. 3.39), which is sufficient for the M2/M5-cocycle to be non-trivial.
- For \( p = 9 \) the \( \mu_{M2} \)-component of \( \mu_{M2/M5} \) vanishes, by Prop. 6.4, and hence here the homotopy would exhibit a coboundary for the NS5-brane cocycle. But, by the old brane scan (Prop. 3.39), this does not exist (meaning that the fundamental NS5-brane does exist in heterotic superspacetime).

We summarize in the following Example how Prop. 6.11 is used iteratively to prove the existence of the equivariantly enhanced cocycles in Theorem 6.1:

Example 6.12 (Components for equivariant enhancement of fundamental brane cocycles). Consider a diagram in rational super homotopy theory (Def. 3.30) of the form

\[
\begin{array}{c}
\mathbb{R}^{d,1|N} \xrightarrow{\mu} S^n \\
\mathbb{R}^{p,1|N/k} \xrightarrow{\mu'} S^{k<n} \\
\end{array}
\]

where \( \mathbb{R}^{d,1|N} \) is a super Minkowski spacetime (Def. 3.36), the left vertical inclusion is that of a fixed BPS subspace from Theorem 4.3, Prop. 4.19, and the right vertical inclusion that of a fixed locus in a sphere, as appearing in Prop. 5.7.

We discuss the data involved in choosing the dashed maps, if the solid maps are given. The sphere coefficients may be represented via their minimal dgc-algebra models, according to Example A.21. Hence if the sphere dimension is odd, then a morphism from a super Minkowski spacetime to it is equivalently a Spin-invariant cocycle in that degree, and classified by the old brane scan (Prop. 3.39). If the sphere coefficient is even, then such a morphism is equivalently one such cocycle in that degree, again classified by the old brane scan, together with a second element that trivialized the product of that cocycle with itself.

In the cases considered below, that cocycle happens to vanish, so that the second element is a cocycle, and classified by the old brane scan. Hence in each case of interest, the choice for \( \mu' \) is classified by an element

\[
[\mu'] \in H^\bullet(\mathbb{R}^{p,1|N/k})^{\text{Spin}(p,1)}
\]

and these are controlled by the old brane scan.

64
We consider the cases where the right vertical map is induced by the inclusion of a sphere of lower dimension into that of higher dimension. These inclusions are all null-homotopic and hence are represented by the zero-homomorphism on the representing dgc-algebras, as in Prop. 5.7. This means that, independently of the choice of the cocycle \(\mu'\), the homotopy \(\eta\) is a null homotopy trivializing the restriction of \(\mu\) along the fixed super subspace inclusion. By Example A.23 these are given by coboundaries \(\alpha\) in the corresponding dg-algebra: \(d\alpha = \iota^* (\mu) \in \text{CE}(\mathbb{R}^{p,1}|N/k)\). By Prop. 6.11 in all cases considered in the following, one such choice is the super volume form \(\text{svol}_{p+1}\), hence the Green–Schwarz Lagrangian (Prop. 6.10).

If \(\alpha\) is any other choice, it follows that the difference \(\text{svol}_{p+1} - \alpha\) is a cocycle, and it is non-trivial as a cocycle precisely if the corresponding two homotopies are not themselves related by a higher homotopy. Hence, in the examples considered in the following, the space of choices for \(\eta\) is in each case the vector space \(H^{p+1} (\mathbb{R}^{p,1}|N/k)\), again given by the old brane scan:

\[
[\eta] = [\text{svol}_{p+1}] + H^{p+1} (\mathbb{R}^{p,1}|N/k).
\] (63)

This concludes the analysis of the available choices of components for equivariant enhancement of fundamental brane cocycles, and hence completes the proof of Theorem 6.1.

A Mathematics background and conventions

For ease of reference, here we collect some standard background material that we use in the main text: on Spacetime and Spin in Section A.1 and on Homotopy and Cohomology in Section A.2.

A.1 Spacetime and Spin

For reference and to fix some essential conventions, we briefly recall some details on real Spin representations in Lorentzian signature.

**Definition A.1** (Spin-geometry of Minkowski spacetime). For \(p \in \mathbb{N}\) we write \(\mathbb{R}^{p,1}\) for the corresponding Minkowski spacetime. The underlying real vector space is \(\mathbb{R}^{p+1}\).

(i) With its canonical coordinate functions labeled as \((x^0, x^1, \ldots, x^p)\), the inner product (Minkowski metric) is taken with the mostly plus signature: for two vectors \(u\) and \(v\) in \(\mathbb{R}^{p,1}\), we have

\[
\eta(u, v) = -u^0 v^0 + u^1 v^1 + \cdots + u^p v^p.
\] (64)

(ii) We write

\[
\mathcal{C}(p, 1) := \mathbb{R}(\Gamma_0, \Gamma_1, \ldots, \Gamma_p)/ (\Gamma_a \cdot \Gamma_b + \Gamma_b \cdot \Gamma_a = +2 \eta_{a,b})
\] (65)

for the Clifford algebra of \(\mathbb{R}^{p,1}\). This is the quotient of the free real associative algebra on \(p+1\) generators \(\Gamma_a\) by the Clifford relation, which says their anticommutator is twice the corresponding entry in the Minkowski metric. We write

\[
\Gamma_{a_1 \cdots a_q} := \frac{1}{q!} \sum_{\sigma \in \Sigma_q} (-1)^{\lvert\sigma\rvert} \Gamma_{a_{\sigma(1)}} \cdot \Gamma_{a_{\sigma(2)}} \cdots \Gamma_{a_{\sigma(q)}}
\] (66)

for the skew-symmetrized products of the Clifford generators.

(iii) Recall the various groups acting on Minkowski spacetime:

- the Lorentz group \(O(p, 1) \hookrightarrow \text{GL}(p + 1)\) is the subgroup of linear transformations that preserve the Minkowski metric [64];

- the orthochronous Lorentz group \(O^+(p, 1) \hookrightarrow O(p, 1)\) is the subgroup of transformations that preserve time-orientation;
• the Pin group $\text{Pin}(p,1) \to \text{O}(p,1)$ is the double cover of the Lorentz group given by the standard Clifford algebraic construction: the group $\text{Pin}(p,1)$ is the subgroup of invertible elements of the Clifford algebra generated by unit vectors in $\mathbb{R}^{p,1}$:

$$\text{Pin}(p,1) := \{ u \in \mathbb{R}^{p,1} : \eta(u,u) = \pm 1 \} \subseteq C\ell(p,1).$$

A unit vector $u \in \text{Pin}(p,1)$ maps to the reflection in $\text{O}(p,1)$ through the hyperplane orthogonal to $u$, and this map on generators extends to a homomorphism $\text{Pin}(p,1) \to \text{O}(p,1)$. It is well known that this homomorphism is a double cover.

• the orthochronous Pin group $\text{Pin}^+(p,1) \to \text{O}^+(p,1)$ is subgroup of $\text{Pin}(p,1)$ that double covers the orthochronous Lorentz group $\text{O}^+(p,1)$.

• the Spin group $\text{Spin}(p,1) \to \text{SO}^+(p,1)$ is the subgroup of $\text{Pin}(p,1)$ that double covers the connected Lorentz group $\text{SO}^+(p,1)$. In terms of the Clifford algebra, it is the subgroup of invertible elements generated by products of pairs of unit vectors with the same sign:

$$\text{Spin}(p,1) = \{ uv \in C\ell(p,1) : u,v \in \mathbb{R}^{p,1} \text{ and } \eta(u,u) = \eta(v,v) = \pm 1 \}.$$

The Lie group $\text{Spin}(p,1)$ is connected and simply-connected.

• The Lie algebra of $\text{Spin}(p,1)$ is the Lie subalgebra of the Clifford algebra on commutators of vectors:

$$\text{Lie}(\text{Spin}(p,1)) \simeq \{ [u,v] \in C\ell(p,1) : u,v \in \mathbb{R}^{p,1} \}.$$

Note that this subspace is actually a Lie subalgebra with respect to the commutator in $C\ell(p,1)$. The double cover map $\text{Spin}(p,1) \to \text{SO}^+(p,1)$ induces an isomorphism of Lie algebras

$$\text{Lie}(\text{Spin}(p,1)) \simeq \mathfrak{so}(p,1)$$

with the Lorentz Lie algebra $\mathfrak{so}(p,1)$ of the connected Lorentz group $\text{SO}^+(p,1)$.

Note that because the Spin group $\text{Spin}(p,1)$ is connected and simply-connected, we can describe a representation in two ways:

• We can give the action of the generators $uv \in \text{Spin}(p,1)$ on a vector space, where $u$ and $v$ are unit vectors of the same sign.

• We can give the action of the Lie algebra $\mathfrak{so}(p,1)$ on a vector space, and exponentiate to get the action of the Lie group $\text{Spin}(p,1)$. In particular, it suffices to give the action of a basis of the Lie algebra $\{ [u,v] \in C\ell(p,1) : u,v \in \mathbb{R}^{p,1} \}$. A natural choice is the basis given by skew-symmetrized products of two gamma matrices, $\{ \Gamma_{ab} \}$.

**Remark A.2** (Technology for real Spin representations). There are two alternative ways of constructing and handling the real Spin representations that appear in the super-Minkowski spacetimes in Def. 3.36:

• One may carve out real spin representations from complex Dirac or Weyl representations by imposing a reality condition, called the Majorana condition. This is the standard method used in the physics literature. A textbook reference for standard conventions is [CDF91, Section II.7], while a conceptual account is in [FF]. We recall this in Section A.1 below; this serves for comparing the results in Sections 4, 5, and 6 to the bulk of the string theory literature.

• Alternatively one may use the real normed division algebras and matrices over them. The most famous example of this is identifying 4-dimensional spacetime, $\mathbb{R}^{3,1}$, with the $2 \times 2$ complex hermitian matrices, and generating the Weyl representations of $\text{Spin}(3,1)$ on $\mathbb{C}^2$ from the action of these matrices. Yet this sort of construction continues to work for normed division algebras other than $\mathbb{C}$, and for spacetimes other than dimension 4. We recall this approach in Section A.1 below; this serves to streamline the proofs of the theorems in Sections 4, 5, and 6.
Real Pin-representations via Majorana condition

**Proposition A.3** (Real spinors via Majorana conditions on Dirac representations). Let

\[ p + 1 \in \{2\nu, 2\nu + 1\}, \quad \nu \in \mathbb{N}, \quad 2\nu \geq 4. \]

and let \( N = 2^\nu \).

(i) **Dirac representations** (as in [CDF91, Section II.7.1]): There exist complex matrices

\[ \Gamma_a \in \text{End}_\mathbb{C}(\mathbb{C}^N), \quad a \in \{0, 1, \ldots, p\} \]

with the following properties:

\[
\begin{align*}
(\Gamma_0)^2 &= +1, \\
(\Gamma_0)^\dagger &= \Gamma_0,
\end{align*}
\]

(67)

\[
\begin{align*}
(\Gamma_a)^2 &= -1, \\
(\Gamma_a)^\dagger &= -\Gamma_a,
\end{align*}
\]

for \( a, b \in \{1, \ldots, p\} \).

(ii) **Charge conjugation matrices** (as in [CDF91, Section II.7.2]): Moreover, there exist charge conjugation matrices

\[ C(\pm) \in \text{End}_\mathbb{C}(\mathbb{C}^N) \]

with real entries \((C(\pm))^* = C(\pm)\) and related to the above \( \Gamma \)-matrices by

\[ C(\pm)\Gamma = \pm \Gamma^t_a C(\pm) \]

according to the following table:

| \( p + 1 \) | \( C(+) \) | \( C(-) \) |
|-------------|----------|----------|
| 3 + 1       | *        | *        |
| 4 + 1       | *        |          |
| 5 + 1       | *        | *        |
| 6 + 1       | *        |          |
| 7 + 1       | *        | *        |
| 8 + 1       | *        |          |
| 9 + 1       | *        | *        |
| 10 + 1      | *        |          |

(68)

(iii) **Majorana condition** (as in [CDF91, Section II.7.3]): Given a Dirac spinor \( \psi \in \mathbb{C}^N \) we say that its Dirac conjugate is

\[ \bar{\psi} := \psi^\dagger \Gamma_0. \]

(69)

This \( \psi \) is called a Majorana spinor if its Dirac conjugate equals its Majorana conjugate, which means

\[ \psi^t C = \psi^\dagger \Gamma_0 \quad \Longleftrightarrow \quad \psi \text{ is Majorana.} \]

(70)

(iv) **Majorana Spin representations** (see [FF]): The subspace of Majorana spinors inside \( \mathbb{C}^N \)

\[ \mathbf{N} \subset \mathbb{C}^N. \]

is preserved by multiplication by the \( \Gamma_{ab} \). This set is a basis for \( \mathfrak{so}(p, 1) \) and this defines a real representation of \( \text{Spin}(p, 1) \) on \( \mathbf{N} \) with dimension \( N = 2^\nu \). The Dirac conjugation \( \psi^\dagger \Gamma_0 \) induces on \( \mathbf{N} \) the following quadratic and \( \text{Spin}(p, 1) \)-equivariant spinor-to-vector pairing

\[
\begin{array}{c c c}
\mathbf{N} & \xrightarrow{(-)\Gamma(-)} & \mathbb{R}^{p,1} \\
\psi & \mapsto & (\psi \Gamma^a \psi)^p_{a=0}
\end{array}
\]

(71)
(v) **Majorana Pin representations**: For charge conjugation matrix $C(\pm)$, the action of a single $\Gamma_a$ preserves the Majorana condition. But for $C(-)$ it does not. For $C(-)$ instead the product $i\Gamma_a$ preserves the Majorana condition. We will write

$$\Gamma_a := i\Gamma_a.$$ 

Instead of the relations (67), the relations satisfied by these boldface gamma matrices are the following:

$$\Gamma_a \Gamma_b + \Gamma_b \Gamma_a = +2\eta_{ab},$$  

$$(\Gamma_0)^2 = -1, \quad (\Gamma_0)^\dagger = -\Gamma_0, \quad (\Gamma_a)^2 = +1, \quad (\Gamma_a)^\dagger = +\Gamma_a, \quad \text{for } a \in \{1, \cdots, p\},$$  

(72)

Since now, for $C(-)$, the subspace of Majorana spinors inside $\mathbb{C}^N$ is preserved by the action of each $\Gamma_a$, equipped with this action it is a real representation of the Pin group (Remark A.1)

$$\mathcal{N} \subset \mathbb{C}^N$$

of real dimension $N = 2^\nu$.

**Example A.4** (Real spin representations). The following are the irreducible real representations (up to isomorphism) of Spin($p,1$) (Def. A.1) for values of $p$ of relevance in the main text, obtainable via Prop. A.3:

| Spacetime dimension $p + 1$ | Supersymmetry $\mathcal{N}$ |
|---------------------------|-----------------------------|
| $10 + 1$                  | $32$                        |
| $9 + 1$                   | $16, 16$                    |
| $6 + 1$                   | $16$                        |
| $5 + 1$                   | $8, 8$                      |
| $4 + 1$                   | $8$                         |
| $3 + 1$                   | $4$                         |
| $2 + 1$                   | $2$                         |
| $1 + 1$                   | $1, 1$                      |

We are particularly concerned with the $32$ of Spin($10,1$). Notice that by (68) the charge conjugation matrix in $D = 10 + 1$ is $C(-)$ and hence the gamma matrices representing the Pin($10,1$)-action on $32$ are those from (72).

**Remark A.5** (Notation for Irrep decomposition – Number of supersymmetries). Given irreducible real spinor representations $\mathcal{N}$ or $\overline{\mathcal{N}}$ as in Example A.4 then a general real spinor representation $\Delta$ is a direct sum of these. The multiplicities of the direct summands is traditionally denoted by $\mathcal{N}$ or $\mathcal{N}_{\pm} \in \mathbb{N}$:

$$\Delta = \mathcal{N} \cdot \mathcal{N} \quad \text{or} \quad \Delta = \mathcal{N}_+ \cdot \mathcal{N} \oplus \mathcal{N}_- \cdot \overline{\mathcal{N}}.$$

Hence if the irreducible representations are understood, any other representation may be denoted simply by

$$\mathcal{N} \quad \text{or} \quad (\mathcal{N}_+, \mathcal{N}_-).$$

When these real spinor representations serve as constituents of super Minkowski spacetimes (Def. 3.36) one calls the natural numbers $\mathcal{N}$ or $\mathcal{N}_\pm$ the *number of supersymmetries*.
Spinor representations via normed division algebras

The observation that real Spin\((p, 1)\)-representations for \(p + 1 \in \{3, 4, 5, 6, 7, 10, 11\}\) may be related to the real division algebras is due to [KuTo82]. A comprehensive account is given in [BH10, BH11]. Here we briefly recall the facts that we need.

**Definition A.6** (Cayley–Dickson construction). Let \(A\) be a real star-algebra (unitual, but not necessarily commutative nor associative), with star involution denoted by \((-)^\ast\). Then its Cayley–Dickson double \(CD(A)\) is the real star algebra obtained by adjoining a new generator \(\ell\) subject to the following relations:

\[
\ell^2 = -1, \quad \text{and} \quad a(\ell b) = (ab)\ell, \quad (a\ell)b = \ell(ab), \quad (\ell a)(b\ell^{-1}) = \overline{ab}
\]  

for all \(a, b \in A\). This implies that the underlying real vector space is

\[CD(A) \cong_{\mathbb{R}} A \oplus \ell A.\]

**Example A.7** (The four real normed division algebras). The first iterations of the Cayley–Dickson construction (Def. A.6) yield the real algebras of

1. real numbers \(\mathbb{R}\),
2. complex numbers \(\mathbb{C} \cong CD(\mathbb{R})\),
3. quaternions \(\mathbb{H} \cong CD(\mathbb{C})\),
4. octonions \(\mathbb{O} \cong CD(\mathbb{H})\).

These four algebras also happen to be precisely the finite-dimensional ‘normed division algebras’ over the real numbers. Recall that a normed division algebra \(K\) is a real algebra, not necessarily associative, with unit 1 and equipped with a norm \(\|\cdot\|\) such that:

\[\|xy\| = \|x\|\|y\| \quad \text{for all} \quad x, y \in K.\]

We say that an algebra equipped with such a norm is normed. Note that being normed immediately implies that \(K\) has no zero divisors, so \(K\) is indeed a division algebra.

Remarkably, there are only four normed division algebras: \(\mathbb{R}, \mathbb{C}, \mathbb{H}\) and \(\mathbb{O}\), constructed above. In the first step of this construction, going from \(\mathbb{R}\) to \(\mathbb{C}\), the adjoined generator \(\ell\) is identified with the imaginary unit \(i \in \mathbb{C}\). In the second step the adjoined generator is usually denoted \(j\), leading to the imaginary quaternions subject to the relations

\[ij = k, \quad ji = -k,\]

and their cyclic permutations. When working with the octonions, we will exclusively use the Cayley–Dickson presentation, and hence in the main text \(\ell\) always denotes a unit octonion orthogonal to \(i, j\) and \(k := ij\).

Notice simple but important relations implied by (73), such as \(\ell^{-1} = -\ell\), which lead to manipulations such as

\[\overline{\ell} = -k\ell = k\ell^{-1}.\]

**Proposition A.8** (Basic properties of the quaternions). We collect some well-known facts about quaternions (Example A.7):

(i) The quaternions \(\mathbb{H}\) are isomorphic to \(\mathbb{R}^4\) as a normed vector space:

\[\mathbb{H} \cong \mathbb{R}^4.\]

(ii) A quaternion \(q \in \mathbb{H}\) of unit norm \(|q| = 1\) is also called a unit quaternion, for short. As a submanifold of \(\mathbb{H}\), the space of unit quaternions is the 3-sphere

\[S(\mathbb{H}) \cong S^3.\]

Quaternion multiplication turns \(S(\mathbb{H})\) into a Lie group. This group is isomorphic to \(SU(2)\):

\[S(\mathbb{H}) \cong SU(2).\]
Thanks to quaternion multiplication, the group SU(2) acts on \( \mathbb{H} \) in two ways (Def. 3.7):

\[
\begin{align*}
SU(2) \times \mathbb{H} & \xrightarrow{\rho_L} \mathbb{H} \\
(q, v) & \mapsto qv \\
SU(2) \times \mathbb{H} & \xrightarrow{\rho_R} \mathbb{H} \\
(q, v) & \mapsto v q
\end{align*}
\]

(77)

These actions commute with each other because \( \mathbb{H} \) is associative, and they preserve the norm because \( \mathbb{H} \) is normed:

\[
|qv| = |q| |v| = |v|
\]

with a similar calculation for the right action. Finally, in either case SU(2) acts on \( \mathbb{H} \) by orientation-preserving transformations, because SU(2) is connected. In summary, the two actions \( \rho_{L,R} \) of SU(2) factor through the special orthogonal group in 4 dimensions:

\[
\rho_{L,R} : SU(2) \rightarrow SO(4)
\]

(78)

Because the actions \( \rho_L \) and \( \rho_R \) commute with each other, they define an action of \( SU(2) \times SU(2) \) on \( \mathbb{H} \). Restricting this to the diagonal SU(2) subgroup, we get an action of SU(2) on \( \mathbb{H} \):

\[
SU(2) \times \mathbb{H} \rightarrow \mathbb{H} \\
(q, v) \mapsto qv \bar{q}
\]

This action is trivial on the real quaternions, and preserves the 3-dimensional subspace of imaginary quaternions. In fact, \( \mathbb{H} \) decomposes into the irreducible representations:

\[
\mathbb{H} \simeq \mathbb{R} \oplus \text{Im}(\mathbb{H}).
\]

The action of SU(2) on the summand \( \text{Im}(\mathbb{H}) \) preserves the norm, and this induces the famous homomorphism

\[
SU(2) \rightarrow SO(3),
\]

(79)

a double cover of SO(3).

The finite subgroups of SU(2) are of particular interest in the main text:

**Remark A.9** (The finite subgroups of SU(2) [Klein1884]). The finite subgroups of SU(2) are given, up to conjugacy, by the following classification (where \( n \in \mathbb{N} \)):

| Label | Finite subgroup of SU(2) | Name of group |
|-------|-------------------------|---------------|
| \( A_n \) | \( \mathbb{Z}_{n+1} \) | Cyclic |
| \( D_{n+4} \) | \( 2\mathbb{D}_{n+2} \) | Binary dihedral |
| \( E_6 \) | \( 2T \) | Binary tetrahedral |
| \( E_7 \) | \( 2O \) | Binary octahedral |
| \( E_8 \) | \( 2I \) | Binary icosahedral |

The full proof for the case of finite subgroups of SL(2, \( \mathbb{C} \)) is given in [MBD1916], recalled in detail in [Ser14, Section 2]. Full proof for the case of SO(3) is also spelled out in [Ree05, Theorem 11]; from this the proof for the case of SU(2) is spelled out in [Kee03, Theorem 4].

**Definition A.10** (Hopf fibration). Let \( K \) be one of the four normed division algebras (Example A.7). Then the corresponding Hopf fibration is the map between unit spheres that is given by

\[
S(\mathbb{K}^2) \xrightarrow{H_K} S(\mathbb{R} \oplus \mathbb{K}) \\
(x, y) \mapsto (|y|^2 - |x|^2, 2x \bar{y})
\]

(80)

where \( S(V) \) denotes the unit sphere inside the normed vector space \( V \). The image lies in \( S(\mathbb{R} \oplus \mathbb{K}) \) because the normed division algebra is normed.
Hence we have

| Normed algebra | Hopf fibration |
|----------------|---------------|
| \( \mathbb{R} \) | \( S^1 \) → \( S^1 \) |
| \( \mathbb{C} \) | \( S^3 \) → \( S^2 \) |
| \( \mathbb{H} \) | \( S^7 \) → \( S^4 \) |
| \( \mathbb{O} \) | \( S^{15} \) → \( S^8 \) |

The key statement for us is the following:

**Proposition A.11** (Real spin representations via real normed division algebras (see [BH10, BH11]). Let \( \mathbb{K} \in \{ \mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O} \} \) be one of the normed division algebras (Example A.7). Write \( \mathfrak{h}_2(\mathbb{K}) \) for the real vector space of \( 2 \times 2 \) hermitian matrices with coefficients in \( \mathbb{K} \):

\[
\mathfrak{h}_2(\mathbb{K}) := \left\{ \begin{pmatrix} t + x & y \\ y & t - x \end{pmatrix} : t, x \in \mathbb{R}, y \in \mathbb{K} \right\}.
\]

Let \( k \) denote the dimension of \( \mathbb{K} \). Then:

1. There is an isomorphism of inner product spaces (“forming Pauli matrices over \( \mathbb{K} \”)

\[(\mathfrak{h}_2(\mathbb{K}), -\det) \cong (\mathbb{R}^{k+1,1}, \eta)\]

identifying \( \mathbb{R}^{k+1,1} \) equipped with its Minkowski inner product

\[
\eta(A, B) := -A^0 B^0 + A^1 B^1 + \cdots + A^{k+1} B^{k+1}, \text{ for } A, B \in \mathbb{R}^{k+1,1}
\]

with the space of \( 2 \times 2 \) hermitian matrices equipped with the negative of the determinant operation.

2. Let \( \mathbf{N} \) and \( \overline{\mathbf{N}} \) both denote the vector space \( \mathbb{K}^2 \). Then \( \mathbf{N} \oplus \overline{\mathbf{N}} \) is a module of the Clifford algebra \( \text{Cl}(k + 1, 1) \), with the action of a vector in \( A \in \mathbb{R}^{k+1,1} \) given by

\[
\Gamma(A)(\psi, \phi) = (\tilde{A} L \phi, A_L \psi)
\]

for any element \( (\psi, \phi) \in \mathbf{N} \oplus \overline{\mathbf{N}} \), where we are using the identification of vectors in \( \mathbb{R}^{k+1,1} \) with \( 2 \times 2 \) hermitian matrices. Here \( (\tilde{-}) \) is the operation \( \tilde{A} = A - \text{tr}(A)1 \), and \( (-)_L \) denotes the linear map given by left multiplication by a matrix.

3. Realizing the spin group \( \text{Spin}(k + 1, 1) \) inside the Clifford algebra \( \text{Cl}(k + 1, 1) \) by the standard construction, this induces irreducible representations \( \rho \) and \( \overline{\rho} \) of \( \text{Spin}(k + 1, 1) \) on \( \mathbf{N} \) and \( \overline{\mathbf{N}} \), respectively. Explicitly, recall that \( \text{Spin}(k + 1, 1) \) is the subgroup of the Clifford algebra generated by products of pairs of unit vectors of the same sign:

\[
\text{Spin}(k + 1, 1) = \langle AB \in \text{Cl}(k + 1, 1) : A, B \in \mathbb{R}^{k+1,1} \text{ and } \eta(A, A) = \eta(B, B) = \pm 1 \rangle.
\]

Then restricting the Clifford action to these elements, a generator \( AB \) of \( \text{Spin}(k + 1, 1) \) acts as

\[
\rho(AB) = \tilde{A}_L B_L \text{ on } \mathbf{N}
\]

and as

\[
\overline{\rho}(AB) = A_L \tilde{B}_L \text{ on } \overline{\mathbf{N}},
\]

where again \( (\tilde{-}) \) is the operation \( \tilde{A} = A - \text{tr}(A)1 \), and \( (-)_L \) denotes the linear map given by left multiplication by a matrix.
4. Moving up by one dimension, there is an isomorphism of inner product spaces
\[ \left\{ \begin{pmatrix} x^0 & \tilde{A} \\ A & -x^0 \end{pmatrix} : a \in \mathbb{R}, A \in \mathfrak{h}_2(\mathbb{K}) \right\} \simeq \mathbb{R}^{k+2,1} \]

between the subspace on the right of $4 \times 4$ matrices over $\mathbb{K}$, equipped with the inner product given by 
$-\det(A) + a^2$, and Minkowski spacetime $\mathbb{R}^{k+2,1}$.

5. Let $\mathcal{N}$ denote the vector space $\mathbb{K}^4$. Then $\mathcal{N}$ is a module of the Clifford algebra $\text{Cl}(k+2,1)$ with the action of a vector $A \in \mathbb{R}^{k+2,1}$ given by:
\[ \Gamma(A)\Psi = A_L \Psi \]
for any element $\Psi \in \mathcal{N}$. Here we are using the identification of vectors in $\mathbb{R}^{k+2,1}$ with a subspace of $4 \times 4$ matrices over $\mathbb{K}$, and $(-)_L$ denotes the linear operator given by left multiplication by a matrix.

6. Realizing the spin group $\text{Spin}(k+2,1)$ inside the Clifford algebra $\text{Cl}(k+2,1)$ by the standard construction, this induces an irreducible representation $\rho$ of $\text{Spin}(k+2,1)$ on $\mathcal{N}$. Explicitly, recall that $\text{Spin}(k+2,1)$ is the subgroup of the Clifford algebra generated by products of pairs of unit vectors of the same sign:
\[ \text{Spin}(k+2,1) = \langle AB \in \text{Cl}(k+2,1) : A, B \in \mathbb{R}^{k+2,1} \text{ and } \eta(A, A) = \eta(B, B) = \pm 1 \rangle. \]

Then restricting the Clifford action to these elements, a generator $AB$ of $\text{Spin}(k+2,1)$ acts as
\[ \rho(AB) = A_L B_L \text{ on } \mathcal{N} \]
where again $(-)_L$ denotes the linear map given by left multiplication by a matrix.

7. The representations $\mathbf{N}$, $\overline{\mathbf{N}}$ and $\mathcal{N}$ constructed above are the irreducible real spinor representations in the following table (and as in Example A.4):

| Dimension | Real irreps of $\text{Spin}(p,1)$ | Clifford modules via real normed division algebra |
|-----------|----------------------------------|-----------------------------------------------|
| $D = p + 1$ | $\mathbf{32}$ | $\mathbb{O}^4$ |
| $10 + 1$ | $\mathbf{16}$, $\overline{\mathbf{16}}$ | $\mathbb{O}^2$ |
| $9 + 1$ | $\mathbf{16}$ | $\mathbb{H}^4$ |
| $6 + 1$ | $\mathbf{8}$, $\overline{\mathbf{8}}$ | $\mathbb{H}^2$ |
| $5 + 1$ | $\mathbf{8}$ | $\mathbb{C}^4$ |
| $4 + 1$ | $\mathbf{4}$ | $\mathbb{R}^4 \simeq \mathbb{C}^2$ |
| $3 + 1$ | $\mathbf{2}$ | $\mathbb{R}^2 \simeq \mathbb{R}^2$ |

Here the symbol “$\simeq$” in the last two lines denotes isomorphism of real representations.

Example A.12 (The octonionic presentation of $\mathbf{32}$). We can identify the 32-dimensional vector space $\mathbf{32}$ with the space $\mathbb{O}^4$:

$\mathbf{32} \simeq \mathbb{O}^4$

Under this identification, the Clifford algebra $\text{Cl}(10,1)$ acts on $\mathbf{32}$ by left multiplication by the following $4 \times 4$ matrices with entries in the octonions, written as $2 \times 2$ matrices with $2 \times 2$ blocks:

\[ \Gamma^0 := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \Gamma^1 := \begin{pmatrix} 0 & \tau \\ \tau & 0 \end{pmatrix}, \quad \Gamma^2 := \begin{pmatrix} 0 & \varepsilon \\ \varepsilon & 0 \end{pmatrix}, \quad \Gamma^{i+2} := \begin{pmatrix} 0 & J e_i \\ J e_i & 0 \end{pmatrix}, \quad \Gamma^{10} := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]
Here, besides the imaginary octonions \( e_1, \ldots, e_7 \), we have used the \( 2 \times 2 \) real matrices:

\[
\tau := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \varepsilon := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad J := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.
\]

Defining the tensor product of matrices \( A \) and \( B \) to be the matrix

\[
A \otimes B = \begin{pmatrix}
a_{11}B & a_{12}B & \cdots & a_{1n}B \\
a_{21}B & a_{22}B & \cdots & a_{2n}B \\
\vdots & \vdots & \ddots & \vdots \\
a_{n1}B & a_{n2}B & \cdots & a_{nn}B
\end{pmatrix},
\]

we can rewrite the octonionic gamma matrices \([81]\) as follows:

\[
\Gamma^0 = J \otimes 1, \quad \Gamma^1 = \varepsilon \otimes \tau, \quad \Gamma^2 = \varepsilon \otimes \varepsilon, \quad \Gamma^{i+2} = \varepsilon \otimes J e_i, \quad \Gamma^{10} = \tau \otimes 1.
\]  

(82)

### A.2 Homotopy and cohomology

For reference, here we collect some basics of abstract homotopy theory (Section A.2) and of the associated generalized cohomology theories (Section A.2).

**Homotopy theory**

We briefly recall some basics of homotopy theory, as well as some basic examples of relevance in the main text. For a self-contained introductory account of abstract homotopy theory see [Sch17b]. For minimal background on language of categories required, see [Sch17a, around Remark 3.3], and for a comprehensive reference see [Bor94]. For going deep and far into homotopy theory, see [Lu09-]. For exposition of the foundational role of homotopy theory see [Sh17].

**Definition A.13** (Category with weak equivalences (e.g. [Sch17b, Def. 2.1])). A category with weak equivalences is a category \( \mathcal{C} \) equipped with a choice of sub-class \( W \subset \text{Mor}(\mathcal{C}) \) of its morphisms, called the weak equivalences, such that

1. \( W \) contains all the identity morphisms;
2. if \( f, g \in W \) are composable with composite \( g \circ f \), and if two elements in the set \( \{ f, g, g \circ f \} \) are weak equivalences, then also the third is.

A category with weak equivalences may also be called a homotopy theory.

**Definition A.14** (Homotopy categories (e.g. [Sch17b, Def. 2.30])). Given a category with weak equivalences \( (\mathcal{C}, W) \) (Def. A.13), then its homotopy category is the category \( (\text{Ho})(\mathcal{C}[W^{-1}]) \) equipped with a functor

\[
\gamma: \mathcal{C} \rightarrow \text{Ho}(\mathcal{C}[W^{-1}]),
\]  

(83)

called the localization functor, such that

1. \( \gamma \) sends weak equivalences to actual isomorphisms;
2. \((\text{Ho}(\mathcal{C}[W^{-1}]), \gamma)\) is the universal solution with this property, in that if \( F: \mathcal{C} \rightarrow \mathcal{D} \) is any other functor, to any other category, such that it sends the weak equivalences \( W \) to actual isomorphisms, then \( F \) actually factors through \( \gamma \), up to natural isomorphism

\[
\begin{tikzcd}
\mathcal{C} \arrow{r}{F} \arrow{d}[swap]{\gamma} & \mathcal{D} \\
\text{Ho}(\mathcal{C}[W^{-1}])
\end{tikzcd}
\]

and this factorization is unique up to unique isomorphism.
The following are basic examples of homotopy theories:

**Definition A.15** (Compactly generated topological spaces). By a *topological space* we will always mean a *compactly generated topological space* (e.g. [Sch17b, Def. 3.35]). We write “Spaces” for the category whose objects are compactly generated topological spaces, and whose morphism are continuous functions. For $X, Y$ two such topological spaces, the space

$$\text{Maps}(X, Y) \in \text{Spaces}$$

of continuous functions between them is itself naturally a compactly generated topological space (e.g. [Sch17b, Def. 3.39]) satisfying the universal properties of a mapping space (e.g. [Sch17b, Def. 3.41]).

**Definition A.16** (Classical homotopy theory (e.g. [Sch17b, Def. 3.11])). A continuous function $f: X \to Y$ between topological spaces (Def. A.15) is called a *weak homotopy equivalences* if it induce a bijection between connected components

$$\pi_0(f): \pi_0(X_1) \xrightarrow{\simeq} \pi_0(X_2)$$

and for every $n \in \mathbb{N}$, $n \geq 1$ and every base point $x \in X$ it induces an isomorphism between the $n$th homotopy groups

$$\pi_n(f, x): \pi_n(X_1, x) \xrightarrow{\simeq} \pi_n(X_2, f(x)).$$

The resulting homotopy category (Def. A.14)

$$\text{Ho}(\text{Spaces}) := \text{Ho}(\text{Spaces}[\{\text{weak homotopy equivalences}\}^{-1}])$$

is also called the *classical homotopy category*.

**Example A.17** (Based path spaces). For $X$ any topological space (Def. A.15), equipped with a base point $x \in X$, write

$$P_x X \subset \text{Maps}([0, 1], X)$$

for its *based path space*, the subspace of the space of continuous functions $\gamma: [0, 1] \to X$ from the interval to $X$ which take $0 \in [0, 1]$ to the base point $\gamma(0) = x$. There is then the endpoint evaluation map

$$P_x X \xrightarrow{\text{ev}_1} X$$

Moreover, there is the unique map $P_x X \to \ast$. This is a weak homotopy equivalence (Def. A.16). Observe that a continuous function $\hat{f}$ into a based path space is equivalently a continuous function into $X$ equipped with a homotopy (Def. 3.14) to the function that is constant on the base point:

It turns out that the classical homotopy category is an extremely rich structure. In order to get a handle on these categories, one may filter them in various ways such as to study homotopy types in controlled approximations. A key such approximation is the rational approximation. We recall this as Prop. A.20 below.

**Definition A.18** (Rational homotopy theory (e.g. [Hes06])).

(i) A continuous function $f: X \to Y$ between topological spaces (Def. A.15) is called a *rational weak homotopy equivalences* if it induces a bijection between connected components

$$\pi_0(f): \pi_0(X_1) \xrightarrow{\simeq} \pi_0(X_2)$$

and for every $n \in \mathbb{N}$, $n \geq 1$ and every base point $x \in X^H$ they induce an isomorphism between the rationalized $n$th homotopy groups

$$\pi_n(f, x) \otimes \mathbb{Q}: \pi_n(X_1, x) \otimes \mathbb{Q} \xrightarrow{\simeq} \pi_n(X_2, f(x)) \otimes \mathbb{Q}.$$
(ii) The resulting homotopy category (Def. A.14)
\[ \text{Ho}(\text{Spaces}_\mathbb{Q}) := \text{Ho}(\text{Spaces} \{\text{rational weak homotopy equivalences}\}) \]
is also called the \textit{rational homotopy category}.

(iii) We also consider the full subcategory
\[ \text{Ho}(\text{Spaces}_\mathbb{Q}, \text{nil}, \text{fin}) \]
on those spaces \( X \) which are
- of \textit{finite rational type} i.e. \( H^1(X, \mathbb{Q}) \) and \( \pi_{k \geq 2}(X) \otimes \mathbb{Q} \) are finite-dimensional \( \mathbb{Q} \)-vector spaces for all \( k \geq 2 \);
- \textit{nilpotent} i.e. the fundamental group \( \pi_1(X) \) is a nilpotent group and such that its actions on the higher rational homotopy groups is nilpotent (i.e. making them nilpotent \( \pi_1(X) \)-modules).

The key point about rational homotopy theory (Def. A.18) is that it may be modeled by dg-algebraic means:

\textbf{Definition A.19} (Rational DG-algebraic homotopy theory (e.g. [Hes06])).

(i) We write \( \text{dgcAlg} \) for the category whose objects are differential graded-commutative \( \mathbb{R} \)-algebras and whose morphisms are dg-algebra homomorphisms. A morphism \( \phi: A_1 \rightarrow A_2 \) is called a \textit{quasi-isomorphism} if it induces isomorphisms on all cochain cohomology groups:
\[ H^n(\phi): H^n(A_1) \xrightarrow{\sim} H^n(A_2). \]

(ii) We write the corresponding homotopy category (Def. A.14) as
\[ \text{Ho}(\text{dgcAlg}^{\text{op}}) := \text{Ho}(\text{dgcAlg}^{\text{op}} \{\text{quasi-isomorphisms}\}^{-1}) \]

(iii) We also consider the full subcategory
\[ \text{Ho}(\text{dgcAlg}^{\text{op}}_{\text{fin, cn}}) \]
on those algebras \( A \) which are
- \textit{of finite type} in that they are equivalent to a DGC-algebra that is degreewise finitely generated;
- \textit{connected} in that the unit inclusion \( \mathbb{Q} \rightarrow A \) induces an isomorphism \( \mathbb{Q} \cong H^0(A) \).

(iv) Finally we write\(^\text{16}\)
\[ \int_{S \in \text{Set}} \text{Ho}(\text{dgcAlg}^{\text{op}}_{\text{fin, cn}})^S \] \hspace{1cm} (85)
for the category whose objects are pairs consisting of a set \( S \) and an \( S \)-indexed tuple of objects of the homotopy category of connected finite-type dgc-algebras, and whose morphism are pairs consisting of a function between these sets and a tuple of homomorphisms between the corresponding dgc-algebras.

The following is the classical statement of rational homotopy theory:

\textbf{Proposition A.20} (DG-model for rational homotopy theory ([Su77, BG76], see [Bra18, Thm 2.1.10])). (i) There is an adjunction ([Bor94, Sec. 3])
\[ \text{Ho}(\text{Spaces}) \xleftarrow{\circ} \text{Ho}(\text{dgcAlg}^{\text{op}}) \]
\[ \downarrow \quad \downarrow \]
\[ \text{S} \]
\[ \text{Ho}(\text{Spaces}) \xrightarrow{\text{O}} \text{Ho}(\text{dgcAlg}^{\text{op}}) \]

between the classical homotopy category of topological spaces (Def. A.16) and the opposite of the homotopy category of DGC-algebras (Def. A.19), where \( \text{O} \) denotes the derived functor of forming the DGC-algebra of polynomial differential forms of a topological space.

\(^{16}\) This just reflects the fact that a map from one disjoint union of connected spaces to another is simply a tuple of maps between connected spaces, one from each connected component of the domain to a connected component of the codomain.
(ii) This adjunction restricts to an equivalence of categories ([Bor94, Sec. 1])

\[
\text{Ho}(\text{Spaces}_{\mathbb{Q}, \text{cn}, \text{nil}, \text{fin}}) \xrightarrow{\sim} \text{Ho}(\text{dgcAlg}_{\text{fin}, \text{cn}}^\text{op})
\]

(86)

between the rational homotopy category of connected nilpotent spaces of finite type (Def. [A.18]) and the homotopy category of connected DGC-algebras of finite type (Def. [A.19]).

(iii) Dropping the connectedness assumption on the left, this extends to an equivalence

\[
\text{Ho}(\text{Spaces}_{\mathbb{Q}, \text{nil}, \text{fin}}) \xrightarrow{\sim} \bigcup_{S \in \text{Set}} \text{Ho}(\text{dgcAlg}_{\text{fin}, \text{cn}}^\text{op})^S
\]

(87)

with the category (85) on the right.

**Example A.21** (Minimal DGC-algebra model for the $n$-spheres). Under the equivalence A.20 the minimal DGC-algebra models of the $n$-spheres are, up to isomorphism as follows:

i) The minimal dgc-algebra model for the 0-sphere consists of two copies of the plain algebra of real numbers:

\[
\mathcal{O}(S^0) = \text{CE}(\{(S^0)\}) := \{\mathbb{R}, \mathbb{R}\}.
\]

(88)

ii) The minimal dgc-algebra model for the odd-dimensional spheres $S^{2n+1}$ are

\[
\mathcal{O}(S^{2n+1}) = \text{CE}(\{S^{2n+1}\}) := \mathbb{R}[h_{2n+1}]/(dh_{2n+1} = 0).
\]

(89)

iii) The minimal dgc-algebra model for the positive even-dimensional spheres $S^{2n+2}$ are

\[
\mathcal{O}(S^{2n+2}) = \text{CE}(\{S^4\}) := \mathbb{R}[\omega_{2n+2}, \omega_{4n+3}]/\left(\begin{array}{l}
d\omega_{2n+2} = 0 \\
d\omega_{4n+3} = -\frac{1}{2}\omega_{2n+2} \wedge \omega_{2n+2}
\end{array}\right).
\]

(90)

iv) Hence for $k \in \mathbb{N}$, there is a canonical map

\[
\begin{array}{c}
S^{4k+3} \dl{\omega_{2k+2}} \dr{h_{4k+3}} \simeq S^{2k+2} \\
0 \quad \omega_{4k+3}
\end{array}
\]

(91)

which represents a non-torsion homotopy class. For $k \in \{0, 1, 3\}$ this is the (rational image of) the complex, quaternionic or octonionic Hopf fibration (Def. [A.10]), respectively.

**Example A.22** (dg-Cocycles as maps in rational homotopy theory). Let

\[
\text{CE}(b^n \mathbb{R}) := \mathbb{R}[\sum_{\deg=n+1} c] \in \text{dgcAlg}
\]

be the dgc-algebra (Def. [A.19]) whose underlying graded-commutative algebra is freely generated from a single generator in degree $n + 1$, and whose differential vanishes. Under the Sullivan equivalence (Prop. [A.20]) these are minimal models of the Eilenberg Mac-Lane spaces (Example A.25)

\[
B^{n+1} \mathbb{R} = K(\mathbb{R}, n + 1) \in \text{Spaces}
\]

in that $\mathcal{O}(B^{n+1} \mathbb{R}) \simeq \text{CE}(b^n \mathbb{R})$. Then for $A \in \text{dgcAlg}$ any dgc-algebra, a dg-algebra homomorphism of the form

\[
A \xleftarrow{\mu^*} \text{CE}(b^n \mathbb{R})
\]

which, under the Sullivan equivalence (Prop. [A.20]), is a model for a map of spaces

\[
S(A) \longrightarrow B^{n+1} \mathbb{R},
\]
is equivalently an element \( \mu \in A \) of degree \( n+1 \), which is closed \( d\mu = 0 \in A \). Hence this is a \textit{cocycle} in the cochain cohomology of the cochain complex underlying \( A \).

Now under the Sullivan equivalence (Prop. \ref{A.20}), the dg-algebra on the right is a model for the Eilenberg-MacLane space \( K(\mathbb{R}, n+1) \)

\[
\text{CE}(b^n\mathbb{R}) \simeq O(K(\mathbb{R}, n+1))
\]

and hence the dg-cocycle \( \mu \) is realized equivalently as map of spaces of the form

\[
S(A) \xrightarrow{\mu := S(\mu^*)} K(\mathbb{R}, n+1).
\]

\textbf{Example A.23} (dg-Coboundaries as homotopies in rational homotopy theory). Let

\[
A_1 \xleftarrow{\mu_0, \mu_1^*} \text{CE}(b^n\mathbb{R})
\]

be two dg-algebra homomorphisms as in Example \ref{A.22}, hence equivalently two dg-cocycles of degree \( n+1 \) in the given dg-algebra \( A \). Then a \textit{dg-homotopy} between these homomorphisms is a dg-algebra homomorphism of the form

\[
A \otimes \Omega^\bullet_{\text{poly}}([0,1]) \xleftarrow{\eta^*} \text{CE}(b^n\mathbb{R})
\]

to the tensor product algebra of \( A \) with the de Rham algebra \( \Omega^\bullet_{\text{poly}}([0,1]) \) of polynomial differential forms on the unit interval, such that its restriction to the endpoints of the interval reproduces the given homomorphisms, respectively.

Explicitly: if we write \( t \in \Omega^0_{\text{poly}}([0,1]) \) for the canonical coordinate function, this means equivalently that \( \eta^* \) corresponds to an element

\[
\eta = \alpha + dt \wedge \beta, \quad \in A \otimes \Omega^\bullet_{\text{poly}}([0,1]) \quad \alpha, \beta \in A \otimes [R][t]
\]

of degree \( n+1 \), such that \( d\eta = 0 \in A \otimes \Omega^\bullet_{\text{poly}}([0,1]) \), hence such that

\[
d(\alpha(t)) = 0 \quad \in A \quad d(\beta(t)) = \frac{\partial}{\partial t} \alpha(t)
\]

and satisfying \( \alpha(0) = \mu_0 \) and \( \alpha(1) = \mu_1 \). For example, if \( \omega \in A \) is a coboundary between the two cocycles, in the sense of the cochain cohomology of \( A \):

\[
d\omega = \mu_1 - \mu_0 \in A,
\]

then we get such an \( \eta \) by setting

\[
\eta := (1-t)\mu_0 + t\mu_1 + dt \wedge \omega.
\]

Therefore, under the Sullivan equivalence (Prop. \ref{A.20}) a coboundary \([93]\) between dg-cocycles corresponds to a homotopy (Def. \ref{3.14}) between the corresponding maps of spaces \([92]\):

\[
S(A) \xrightarrow{\mu_0} K(\mathbb{R}, n+1) \xleftarrow{\mu_1} S(\eta^*).
\]
Cohomology

Our main interest in homotopy theories (Def. A.13) here is that each flavor of homotopy theory induces a corresponding generalized cohomology theory (Def. A.24 below). This includes Eilenberg-Steenrod-type generalized cohomology theories (Example A.25 below), which are often just called “generalized cohomology theory”, for short, but is in fact much more general than that: all kinds of differential and/or twisted and/or non-abelian and/or equivariant and/or orbifolded and/or ... concepts of cohomology theories arise via the simple Definition A.24 from a suitably chosen ambient homotopy theory.

In the main text we are interested in this general concept of generalized cohomology in order to set up and study the cohomology theory equivariant rational cohomotopy of superspaces (Sec. 5).

Definition A.24 (Generalized cohomology theories from homotopy theory). Every homotopy theory induces a corresponding generalized cohomology theory: given a category with weak equivalences \((C, W)\) (Def. A.13) and any object \(A \in C\) then

- a morphism \(c: X \to A\) in \(C\) is an \(A\)-valued cocycle on \(X\);
- the equivalence relation on such morphisms induced by the localization functor (83) is the coboundary relation;
- the image of \([c] := \gamma(c)\) in the morphisms of the homotopy category \(Ho(C[W]^{-1})\) (Def. A.14) is the cohomology class of the cocycle.

Hence the set of \(A\)-valued cohomology classes on \(X\) is

\[ H(X, A) := \text{Hom}_{Ho(C[W]^{-1})}(X, A). \]

Example A.25 (Examples of generalized cohomology theories). Examples of generalized cohomology theories arising from homotopy theories via Def. A.24 include the following:

- For \((C, W)\) the category of spectra with stable weak homotopy equivalences (see e.g. [Sch17c, Def. I.4.1]), the corresponding cohomology theories are equivalently the abelian generalized cohomology theories in the sense of the Eilenberg-Steenrod axioms. This is the statement of the Brown representability theorem (see e.g. [Sch17d, Section 1]). For instance
  - if \(A = \Sigma^n H\mathbb{Z} \in \text{Spectra}\) is an Eilenberg-MacLane spectrum (e.g. [Sch17c, Def. II.6.3]), then this is ordinary cohomology;
  - if \(A := KU := (KU_k)_{k \in \mathbb{Z}} := \{ BU \times \mathbb{Z} \mid k \text{ even } \} \cup \{ U \mid k \text{ odd } \} \) (94)
    this is K-theory (also called complex topological K-theory for emphasis, to distinguish from a wealth of variants, such as (96) below) which measure D-brane charge in type II string theory [Wit98, FrWi99, MoWi00, EvSa06, Evs06].
- For \((C, W)\) the category of spaces with \(W\) the class of weak homotopy equivalences (Def. A.16), the corresponding cohomology theories are called non-abelian cohomology. For instance
  - if \(A = BG \in \text{Spaces}\) is the classifying space of a topological group \(G\), then the corresponding cohomology theory is nonabelian \(G\)-cohomology in degree 1, classifying \(G\)-principal bundles (in physics: \(G\)-instanton sectors);
  - if \(A = S^n \in \text{Spaces}\) is an \(n\)-sphere, then the corresponding non-abelian cohomology theory is called cohomotopy [Spa49].
- For \((C, W)\) the opposite category of dgc-algebras with \(W\) the class of quasi-isomorphisms (Def. A.19), we have that the corresponding cohomology theory is simply cochain cohomology of the underlying cochain complexes (see Example A.23 and Example A.22).
• For \((C, W)\) the \(G\)-equivariant homotopy category (Def. 3.18) or the category of \(G\)-fixed point systems (Def. 3.25), whose homotopy categories are equivalent by Prop. 3.26, the corresponding cohomology theory is called **Bredon equivariant cohomology**, after [Bre67]. For instance

- if \(A \in \text{Spaces}\) represents some cohomology theory, then that space equipped with a \(\mathbb{Z}_2\)-action (Example 3.3)

\[
\begin{array}{ccc}
\mathbb{Z}_2 & \cong & \mathbb{Z}_2 \text{Spaces} \\
\downarrow & & \\
A & \in & \mathbb{Z}_2 \text{Spaces}
\end{array}
\]

represents a corresponding **real cohomology theory** on **real spaces** (Example 3.11). A prominent example is real K-theory (96).

• For \((C, W)\) the \(G\)-equivariant *stable* homotopy category (of spectra with \(G\)-actions), the complex K-theory spectrum (94) equipped with \(\mathbb{Z}_2\)-action

\[
\begin{array}{ccc}
\mathbb{Z}_2 & \cong & \mathbb{Z}_2 \\
\downarrow & & \\
\text{MR} := \text{KU} & \\
\end{array}
\]

where \(e \neq \sigma \in \mathbb{Z}_2\) acts by complex conjugation, represents the real cohomology theory (95) called **real K-theory** [Ati66, HuKr01], which measures D-brane charge in type I string theory, hence in type II string theory in the presence of O-planes, hence on orientifolds [Wit98, Sec. 5.2], [Guk99, Hor99, DFM09, DMR13].

**Remark A.26** (Extra structure on cohomology). For a given coefficient object \(A \in C\) in Def. A.24, the induced generalized cohomology \(H(\_ , A)\) a priori is only a set. This set inherits extra algebraic structure to the extent that \(A \in \text{Ho}(C[W]^{-1})\) is equipped with such extra structure. For instance if \(A\) carries the structure of an (abelian) group in the homotopy category, then \(H(\_ , A)\) takes values in (abelian) cohomology groups. This is often considered by default.

This fails for key examples of cohomology theories, such as notably for cohomotopy theory (Example A.25), (except in those special degrees where the sphere coefficients happen to admit group structure).

But the minimum structure one will usually want to retain is that \(A\) is equipped with a *point*, namely with a morphism

\[
* \xrightarrow{\text{pt}_A} A
\]

in the homotopy category, from the terminal object \(*\), making it a “pointed object”. In this case also the cohomology sets \(H(X, A)\) are canonically pointed sets, namely by the unique cocycle \(X \to * \xrightarrow{\text{pt}_A} A\) that factors through \(\text{pt}_A\). This is then called the **trivial cocycle**, while all other cocycles are **non-trivial**.
