Abstract

In this paper we consider pseudo-Riemannian spaces of arbitrary signature for which all of the polynomial curvature invariants vanish (VSI spaces). We discuss an algebraic classification of pseudo-Riemannian spaces in terms of the boost weight decomposition and define the $S_i$- and $N$-properties, and show that if the curvature tensors of the space possess the $N$-property, then it is a VSI space. We then use this result to construct a set of metrics that are VSI. All of the VSI spaces constructed possess a geodesic, expansion-free, shear-free, and twist-free null congruence. We also discuss the related Walker metrics.

1. Introduction

Let us consider an arbitrary-dimensional pseudo-Riemannian space of signature $(k, k+m)$. We will investigate when such a space can have a degenerate curvature structure; in particular, we shall determine when all of its polynomial curvature invariants vanish (VSI space). Recall that a polynomial curvature invariant is defined as the polynomial invariants of the components of the curvature tensors. Previously, the VSI spaces for Lorentzian metrics have been studied \cite{1} and it was shown that these comprise a subclass of the degenerate Kundt metrics \cite{2}. Here, we will see that Kundt-like metrics also play a similar role for pseudo-Riemannian VSI metrics of arbitrary signature. In order to study such VSI metrics we will utilize curvature operators since any curvature invariant is the trace of some curvature operator \cite{3}. We will use this fact to construct a set of metrics with vanishing curvature invariants. All of the metrics constructed possess a null vector that is geodesic, shear-free, vorticity-free and expansion-free.

Let us first review the boost weight classification, originally used to study degenerate metrics in Lorentzian geometry \cite{4}, in the pseudo-Riemannian case \cite{5}. The symmetry group of frame-rotations in this case is $SO(k, k+m)$. Any element $G$ can be written $G = KAN$ (the Iwasawa decomposition; e.g., see \cite{6}), where we have split it up into a compact spin piece,
K, an Abelian boost piece, A, and a piece consisting of null rotations, N. For \( SO(k, k+m) \), \( K \in SO(m) \), and there are \( k \) independent boosts (which equals the real rank of \( SO(k, k+m) \)).

Therefore, we first introduce a suitable null frame such that the metric can be written as

\[
d\ell^2 = 2 \left( \ell^i n^i + \cdots + \ell^i n^i + \cdots + \ell^k n^k \right) + \delta_{ij} m^i m^j ,
\]

where the indices \( i = 1, \ldots, m \). The spins will act on \( m^i \), each boost will act on the pair of null vectors, while the null rotations will in general mix up null vectors and spatial vectors.

More precisely\(^3\),

spins: \( \ell^I = \ell^I, \quad n^I = n^I, \quad \tilde{m}^I = M^I m^I, \quad (M^I) \in SO(m) \), \( (1) \)

boosts: \( \ell^I = e^{\lambda I} \ell^I, \quad n^I = e^{-\lambda I} n^I, \quad \tilde{m}^I = m^I \), \( (2) \)

while the null rotations can be split up at each level. Considering the subset of forms \( (\ell^I, n^I, \omega_{\mu I}) \), where \( \omega_{\mu I} = \{ \ell^{I+1}, n^{I+1}, \ldots, \ell^k, n^k, m^I \} \), we can consider the \( I \)th level null rotations with respect to \( n^I \):

null-rot: \( \tilde{\ell}^I = \ell^I - z_{\mu I} \omega_{\mu I} - \frac{1}{2} z_{\mu I} z_{\mu I} n^I, \quad \tilde{n}^I = n^I, \quad \tilde{\omega}_{\mu I} = \omega_{\mu I} + z_{\mu I} n^I \), \( (4) \)

and similarly for \( \ell^I \). Note that there are \( 2(2k + m - 2I) \) null rotations at the \( I \)th level, making \( 2k(k + m - 1) \) in total.

1.1. Boost weight decomposition

Let us consider the \( k \) independent boosts:

\[
(\ell^1, n^1) \mapsto (e^{\lambda_1} \ell^1, e^{-\lambda_1} n^1) \\
(\ell^2, n^2) \mapsto (e^{\lambda_2} \ell^2, e^{-\lambda_2} n^2) \\
\vdots
\]

\[
(\ell^k, n^k) \mapsto (e^{\lambda_k} \ell^k, e^{-\lambda_k} n^k).
\]

For a tensor \( T \), we can then consider the boost weights of this tensor, \( b \in \mathbb{Z}^k \), as follows. If we consider the components of \( T \) with respect to the above-mentioned null frame, then if a component \( T_{\mu_1 \cdots \mu_n} \) transforms as

\[
T_{\mu_1 \cdots \mu_n} \mapsto e^{-\gamma_{\mu_1 \lambda_1 + \cdots + \mu_n \lambda_n}} T_{\mu_1 \cdots \mu_n},
\]

we will say that the component \( T_{\mu_1 \cdots \mu_n} \) is of boost weight \( b = (b_1, b_2, \ldots, b_k) \). We can now decompose a tensor into boost weights; in particular,

\[
T = \sum_{b \in \mathbb{Z}^k} (T)_b,
\]

where \( (T)_b \) means the projection onto the components of boost weight \( b \). The projections \( (T)_b \) are the eigentensors of a set of commuting operators (the boosts) with integer eigenvalues.

By considering tensor products, the boost weights obey the following additive rule:

\[
(T \otimes S)_b = \sum_{b \cdot b = b} (T)_b \otimes (S)_b.
\]

\(^3\) In a pseudo-Riemannian space, the spins can be interpreted as spatial rotations and, in analogy to the Lorentzian case, the boost can be interpreted as a boost with respect to a timelike curve.
1.2. The \( S_i \) - and \( N \)-properties

Let us consider a tensor, \( T \), and list a few conditions that the tensor components may fulfill:

**Definition 1.1.** We define the following conditions:

\[
(B1) \quad (T)_b = 0, \text{ for all } b = (b_1, b_2, b_3, \ldots, b_k), \quad b_1 > 0.
\]

\[
(B2) \quad (T)_b = 0, \text{ for all } b = (0, b_2, b_3, \ldots, b_k), \quad b_2 > 0.
\]

\[
(B3) \quad (T)_b = 0, \text{ for all } b = (0, 0, b_3, \ldots, b_k), \quad b_3 > 0.
\]

\[
(Bk) \quad (T)_b = 0, \text{ for all } b = (0, 0, \ldots, 0, b_k), \quad b_k > 0.
\]

**Definition 1.2.** We will say that a tensor \( T \) possesses the \( S_i \)-property if and only if there exists a null frame such that condition \( (B1) \) above is satisfied. Furthermore, we say that \( T \) possesses the \( S_i \)-property if and only if there exists a null frame such that conditions \( (B1) \)–\( (Bk) \) above are satisfied.

**Definition 1.3.** We will say that a tensor \( T \) possesses the \( N \)-property if and only if there exists a null frame such that conditions \( (B1) \)–\( (Bk) \) in definition 1.1 are satisfied, and

\[
(T)_b = 0, \quad \text{ for } b = (0, 0, \ldots, 0).
\]

**Proposition 1.4.** For tensor products we have:

1. Let \( T \) and \( S \) possess the \( S_i \)- and \( S_j \)-property, respectively. Assuming, with no loss of generality, that \( i \leq j \), then \( T \otimes S \) possesses the \( S_i \)-property.

2. Let \( T \) and \( S \) possess the \( S_i \)- and \( N \)-property, respectively. Then \( T \otimes S \) possesses the \( S_i \)-property. If \( i = k \), then \( T \otimes S \) possesses the \( N \)-property.

3. Let \( T \) and \( S \) both possess the \( N \)-property. Then \( T \otimes S \), and any contraction thereof, possesses the \( N \)-property.

**Proof.** We note that conditions \( (B1) \)–\( (Bk) \) are preserved under vector addition, i.e. if \( b \) and \( \tilde{b} \) fulfill conditions \( (B1) \)–\( (Bk) \), then so will \( b = b + \tilde{b} \). Consequently, using equation (6), \( (i) \) follows. If \( S \) fulfills the \( N \)-property, it must also fulfill the \( S_k \)-property. This implies, from equation (6), that \( T \otimes S \) fulfills the \( S_i \) property if \( T \) does. If \( T \) fulfills the \( S_i \) property, then the only non-zero components can come from products of \( (0, 0, \ldots, 0) \) components of \( T \) and \( S \). However, since \( S \) fulfills the \( N \)-property, these products must be zero: consequently, \( (ii) \) follows. Finally, \( (iii) \) follows from \( (ii) \) and the fact that the metric has boost-weight \( (0, 0, \ldots, 0) \) so that raising and lowering indices do not change boost weight. \( \square \)

It is also useful to define a set of related conditions. Consider a tensor, \( T \), that does not necessarily meet any of the conditions above. However, since the boost weights \( b \in \mathbb{Z}^k \subset \mathbb{R}^k \), we can consider a linear \( GL(k) \) transformation, \( G : \mathbb{Z}^k \rightarrow \Gamma \), where \( \Gamma \) is a lattice in \( \mathbb{R}^k \).

Now, if there exists a \( G \) such that the transformed boost weights, \( Gb \), satisfy (some) of the conditions in definition 1.1, we will say, correspondingly, that \( T \) possesses the \( S_i^G \)-property. Similarly, for the \( N^G \)-property.

If we have two tensors \( T \) and \( S \) both possessing the \( S_i^G \)-property, with the same \( G \), then when we take the tensor product:

\[
(T \otimes S)_G = \sum_{Gb \cdot Gb = Gb} (T)_G \otimes (S)_G.
\]
Therefore, the tensor product will also possess the $S^G_i$-property, with the same $G$. This will be useful later when considering degenerate tensors and metrics with degenerate curvature tensors. Note also that the $S^G_i$-property reduces to the $S_i$-property for $G = I$ (the identity).

**Remark 1.5.** A tensor, $T$, satisfying the $S^G_i$-property or $N^G_i$-property is not generically determined by its invariants in the sense that there may be another tensor, $T'$, with precisely the same invariants. The $S_i$-property thus implies a certain degeneracy in the tensor.

### 1.3. The VSI properties

We can now state two results that will be useful.

**Theorem 1.6.** A pseudo-Riemannian space is VSI if and only if all the curvature operators are nilpotent.

**Proof.** The proof of this follows almost directly from [3]. In particular, consider a curvature operator $T$. Then:

- All invariants $\text{Tr}(T^k)$ are zero.
- All eigenvalues of $T$ are zero.
- $T$ is nilpotent.

Since any polynomial curvature invariant is the trace of some curvature operator, the theorem follows.

Hence, if a curvature operator is nilpotent, then we know that all of its invariants are zero. The next result gives us a necessary criterion for when an operator is nilpotent.

**Theorem 1.7.** If an even-ranked tensor $T$ possesses the $N^G_i$-property, then the operator $T$ (obtained by raising/lowering indices) is nilpotent.

**Proof.** This result follows from an equivalent proof to that in [3], which we will include here for completeness. We note that since $T$ possesses the $N^G_i$-property, so do $T \otimes T$, $T \otimes T \otimes T$, etc. Moreover, since the metric $g$ is of boost weight zero, the operators $T^k$ also possess the $N^G_i$-property. The coefficients of the eigenvalue equation of $T$ consist of traces of $T^k$ which necessarily has zero boost weight; thus, we get $\text{Tr}(T^k) = 0$ and all eigenvalues are consequently zero. This implies that $T$ is nilpotent.

### 2. Invariant null planes: Walker metrics

A set of vectors $\ell^I$, $I = 1, \ldots, k'$, is said to span a $k'$-dimensional invariant plane if the $k'$-vector, $\ell^1 \wedge \ldots \wedge \ell^{k'}$, is recurrent. Using the dual one-forms, with components $\ell^1_\mu$, the recurrent requirement is equivalent to

$$(\ell^1_\mu_1 \ell^2_\mu_2 \ldots \ell^{k'}_\mu_{k'})_\nu = \ell^1_{\mu_1} \ell^2_{\mu_2} \ldots \ell^{k'}_{\mu_{k'}} k_\nu,$$

where $k_\nu$ is some vector. We can interpret this as requiring that the volume form of the invariant plane to be recurrent.

4 Note that for an even-ranked tensor, we naturally have associated operator(s) by raising/lowering indices. If $T$ is odd ranked, then we can consider the tensor $T \otimes T$ which is even ranked.
If, in addition, the vectors $\ell^1, I = 1, \ldots, k'$, are all null and mutually orthogonal, then the invariant plane is null. Henceforth, we assume that the vectors span a $k'$-dimensional invariant null plane, $\mathcal{N}$. Consider the orthogonal complement, $\mathcal{N}_\perp$. Then, since the volume form of $\mathcal{N}_\perp$ is the Hodge dual of the volume form of $\mathcal{N}$, the complement $\mathcal{N}_\perp$ is also invariant. Note that since $\mathcal{N}$ is null, we have $\mathcal{N} \subset \mathcal{N}_\perp$.

If the pseudo-Riemannian space is a Walker metric, which is defined as a space admitting a $k'$-dimensional invariant null plane $\mathcal{N}$, then since the connection is torsion-free, the set of null vectors $\ell^I \subset \mathcal{N}$ are such that

$$[\ell_I, \ell_J] \subset \mathcal{N}.$$ 

By Frobenius’ theorem, these vectors then span a foliation for which there exists an adapted set of coordinates, $(v^1, \ldots, v^k)$, spanning the null plane, and a complimentary set, $(u^1, \ldots, u^k, x^1)$. Furthermore, Walker [7] showed that we can choose the set of null vectors $\ell_I$ so that $\ell_I = \frac{\partial}{\partial v^I}$, and their dual one-forms are $\ell^I = du^I$.

Let us choose one of these null forms, say $\ell^I = \ell^I du^I = du^I$, and form the null frame $\{\ell^I, n^k, \omega^I\}$. Since this is a null frame, the corresponding connection (spin) coefficients fulfill the fundamental antisymmetry:

$$\Gamma_{\mu\nu\alpha} = -\Gamma_{\nu\mu\alpha}, \quad (7)$$

where $\Gamma_{\mu\nu\alpha} = g_{\mu\nu} \Gamma^\alpha$. Furthermore, using the Frobenius theorem for both $\mathcal{N}$ and $\mathcal{N}_\perp$, we get

$$d\ell^I = 0, \quad d\omega^I = -\frac{1}{2} \epsilon^{ijk} \omega^j \wedge \omega^k - c_{ij} \ell^I \wedge \omega^j. \quad (8)$$

Using the relation $d\omega^\mu = -\Gamma^\mu_{[\nu\rho]} \omega^{\nu} \wedge \omega^{\rho}$ then implies the vanishing of certain connection coefficients. For example, consider

$$\ell^\mu \nabla_\mu \ell_v = -\Gamma_{00\nu} = -\Gamma_{00\nu} = 0. \quad (9)$$

Hence, $\ell_\mu$ is geodesic. Furthermore, since $d\ell^I = 0$, $\ell_\mu$ is vorticity-free. This implies that we can write the covariant derivative as

$$\ell_{\mu;\nu} = L_{11} \ell_{\mu} \ell_v + L_{1i} \ell_{(i} \omega^j v_{j)} + L_{ij} \omega^i_{\mu} \omega^j_{\nu}, \quad (10)$$

where the $\omega^i_{\mu}$ are the components of $\omega^i$.

Defining the extrinsic curvature and the vorticity

$$K_{ij} = L^{[ij]} = \ell_{(i;\nu)} \omega^j_{\mu} \omega^j_{\nu}, \quad A^{ij} = L^{[ij]} = \ell_{(i;\nu)} \omega^j_{\mu} \omega^j_{\nu},$$

we note that $A_{ij} = 0$ (vorticity-free). Calculating $K_{ij}$,

$$K_{ij} = -\Gamma^{0}_{ij} - \Gamma_{0ij} = \Gamma_{0ij} + \Gamma_{j0i} = \Gamma_{j0} + \Gamma_{j0} = 0.$$ 

Therefore, $K_{ij} = 0$ and $\ell^I$ is expansion-free and shear-free. Consequently, we have

$$\ell_{\mu;v} = L_{11} \ell_{\mu} \ell_v + L_{1i} \ell_{(i} \omega^j v_{j)}. \quad (11)$$

The Walker metrics thus allow for a null vector $\ell^1$ which is geodesic, expansion-free, shear-free, and vorticity-free. In fact, we note that the above metric possesses $k'$ null vectors $\ell^I$ which are geodesic, vorticity-free, shear-free and expansion-free. This is reminiscent of the Kundt form of the metric in Lorentzian geometry. Indeed, this leads us to define pseudo-Riemannian Kundt metrics in analogy to the Lorentzian case. Indeed, these pseudo-Riemannian Kundt metrics will have the Walker metrics as a special case (however, not all pseudo-Riemannian Kundt metrics will be Walker metrics).

Furthermore, Walker [7] showed that the requirement of an invariant $k'$-dimensional null plane implies that the (Walker) metric can be written in the canonical form

$$ds^2 = du^I (2B_{IJ} du^J + B_{IJK} du^J + H_{IJ} dx^k) + A_{ij} \ dx^i \ dx^j, \quad (12)$$

where $B_{IJ}$ is a symmetric matrix which may depend on all of the coordinates, while $H_{IJ}$ and $A_{ij}$ do not depend on the coordinates $v^I$. Note that if the signature is $(k, k + n)$, then $k' \leq k$. If $k' = 1$, then there exists an invariant null line, while if $k' = k$, then the invariant null plane is of maximal dimension.
3. Pseudo-Riemannian Kundt metrics

In the Lorentzian case ($k = 1$) the Kundt metrics play an important role for degenerate metrics, and VSI metrics in particular [1]. Here we will argue that their pseudo-Riemannian analogs also play an important role for pseudo-Riemannian spaces of arbitrary signature.

Let us define the pseudo-Riemannian Kundt metrics in a similar fashion, namely:

**Definition 3.1.** A pseudo-Riemannian Kundt metric is a metric which possesses a non-zero null vector $\ell$ which is geodesic, expansion-free, twist-free and shear-free.

Therefore, we will consider metrics of the form (which is equivalent to the above definition)

$$ds^2 = 2\, du [dv + H(v, u, x^C)\, du + W_A(v, u, x^C)\, dx^A] + g_{AB}(u, x^C)\, dx^A\, dx^B$$

(13)

(here, the indices $A, B$ range over the null indices $I = 2, 3, \ldots$ and spatial indices $i = 1, \ldots, m$). Metric (13) possesses a null vector field $\ell$ obeying

$$\ell_{\mu;\nu} = L_{\mu\beta} \ell_{\beta} + L_{\mu(\rho\omega_i)} \ell_{(\rho;\omega_i)},$$

and consequently,

$$\ell^\mu \ell_{\nu;\mu} = \ell_{\mu;\nu} = \ell_{(\mu;\nu)} = 0;$$

(14)

i.e. it is geodesic, non-expanding, shear-free and non-twisting. If this is a pseudo-Riemannian space of signature $(k, k + m)$, then the transverse metric

$$ds_1^2 = g_{AB}(u, x^C)\, dx^A\, dx^B,$$

will be of signature $(k - 1, k - 1 + m)$.

By using a normalized frame we can calculate the boost weight $b = (1, b_2, \ldots, b_k)$ and $(0, b_2, \ldots, b_k)$ components of the Riemann tensor:

$$R_{0\hat{0}\hat{\lambda}} = -\frac{1}{2} W_{\hat{\lambda},vv},$$

(15)

$$R_{0\hat{0}1} = -H_{vv} + \frac{1}{2} (W_{\hat{\lambda},v})(W_{\hat{\lambda},v}),$$

(16)

$$R_{0\hat{1}\hat{\lambda}\hat{\beta}} = W_{\hat{\lambda}\hat{\beta}} + W_{\hat{\lambda}\hat{\beta}},$$

(17)

$$R_{0\hat{1}\hat{\lambda}\hat{\beta}} = \frac{1}{4} \left[ -W_{\hat{\beta}v} W_{\hat{\lambda},v} + W_{\hat{\lambda},\hat{\beta}} - \frac{1}{2} (W_{\hat{\lambda},\hat{\lambda}})(W_{\hat{\beta},v}) \right].$$

(18)

$$R_{\hat{\lambda}\hat{\beta}\hat{c}\hat{d}} = \tilde{R}_{\hat{\lambda}\hat{\beta}\hat{c}\hat{d}}.$$  

(19)

Note that the Riemann tensor satisfies the $S_1$-property if $R_{0\hat{0}\hat{0}\hat{\lambda}} = -\frac{1}{2} W_{\hat{\lambda},vv} = 0$. Now, whether the Riemann tensor satisfies any of the other requirements depends on the components of boost weight $b = (0, b_2, \ldots, b_k)$:

$$H_{vv} = \frac{1}{2} (W_{\hat{\lambda},v})(W_{\hat{\lambda},v}) = \sigma,$$

(20)

$$W_{\hat{\lambda}\hat{\beta}},v = a_{\hat{\beta}\hat{\lambda}},$$

(21)

$$W_{\hat{\lambda}\hat{\beta}},v = \frac{1}{2} (W_{\hat{\beta},v})(W_{\hat{\lambda},v}) = s_{\hat{\beta}\hat{\lambda}},$$

(22)

and the components $\tilde{R}_{\hat{\lambda}\hat{\beta}\hat{c}\hat{d}}$.

5 If, in addition $L_{\mu} = 0$, the vector $\ell_{\mu}$ is also recurrent, and if $L_{\mu} = L_{11} = 0$, then $\ell_{\mu}$ is covariantly constant.

6
3.1. The N-property and VSI spaces

We can now consider the conditions which are required for these pseudo-Riemannian Kundt metrics to be VSI metrics.

To get a set of necessary conditions we consider the Riemann tensor, $R$, as an operator $R: \wedge^2 T_p M \mapsto \wedge^2 T_p M$, as follows: $R = (R^{\alpha\beta\mu\nu})$. We note that for the pseudo-Riemannian Kundt metrics, if $R^{\hat{0}\hat{1}\hat{0}\hat{0}} = -\frac{1}{2} W_{\hat{A},\nu\nu} = 0$, the question of when $R$ possesses the N-property is related to the values of the components $\sigma$, $a_{\hat{A}\hat{B}}$, $s_{\hat{A}\hat{B}}$ and $\tilde{R}^{\hat{A}\hat{B}\hat{C}\hat{D}}$.

Therefore, a sufficient criterion for the Riemann curvature operator to have only zero polynomial invariants is that $\sigma = 0$ and the matrices

\[
[a_{\hat{A}\hat{B}}], \quad [s_{\hat{A}\hat{B}}], \quad [\tilde{R}^{\hat{A}\hat{B}\hat{C}\hat{D}}]
\]

have only zero-eigenvalues; hence, they are nilpotent.

3.2. Nested Kundt metrics

Consider now the case where the transverse metric $ds_1 = g_{AB}(u, x^C) dx^A dx^B$ of signature $(k-1, k-1+m)$ is also pseudo-Riemannian Kundt. This means that it can also be written in Kundt form (where $u$ is considered as a parameter). The transverse space will now also be independent of one of the null coordinates. Again a special case would be when this transverse space is also pseudo-Riemannian Kundt.

Therefore, let $(v^I, u^I, a_I, b_I = 1, \ldots, I)$ be null coordinates, and $x^\mu I, \mu I = 2, I, \ldots, k + m$ be ‘transverse’ coordinates. We can then consider the $I$th nested Kundt metric:

\[
d s^2_I = 2 du^I \left[ dv^I + H^I(v^I, u^a, x^b) du^I + W^I_{\hat{\mu}I}(v^I, u^a, x^b) dx^\mu I \right] + g^I_{\hat{\mu}I\hat{\nu}I}(u^a, x^b) dx^{\mu I} dx^{\nu I},
\]

for which the boost weight component $b = (0, 0, \ldots, 1, b_I, \ldots, b_k)$ is $-\frac{1}{2} W^I_{\hat{\mu}I\hat{\nu}I\nu I\nu I}$. Similarly, the boost weight $b = (0, \ldots, 0, b_I, \ldots, b_k)$ components can be written in terms of $H^I_{\hat{\mu}I\hat{\nu}I\nu I\nu I} = \frac{1}{2} (W^I_{\hat{\mu}I\hat{\nu}I\nu I\nu I})$, $W^I_{\hat{\mu}I\hat{\nu}I\nu I\nu I}$ can be written in terms of $H^I_{\hat{\mu}I\hat{\nu}I\nu I\nu I}$, and the components $\tilde{R}^I_{\hat{\mu}I\hat{\nu}I\hat{\rho}I\hat{\lambda}I}$.

4. Pseudo-Riemannian Kundt VSI metrics

We can now construct VSI metrics from the nested Kundt metrics by requiring that they fulfill the N-property, and then iteratively solving the above equations for the components. We can assume that the metric is an $I$th order nested Kundt metric and solve for the metric components $H^I$ and $W^I$. We will start out by considering the lower-dimensional cases. In four dimensions (4D), the only case not considered in detail is the neutral $(2, 2)$-signature case. In five dimensions, the only case not considered previously in the literature is the $(2, 3)$-signature case. These two cases will be considered next. We will also give a class of VSI metrics of $(k, k+m)$-signature.
4.1. 4D Neutral case

Let us consider the 4D neutral case which is of particular interest (see, e.g., [8]). Here we can write
\[ ds^2 = 2(\ell^1 n^1 + \ell^2 n^2). \] (27)

We will consider the pseudo-Riemannian Kundt case and at the first level the transverse space is two dimensional. Consequently, there is only one independent component of the Riemann tensor, namely \( \tilde{R}_{3434} \). This is of boost weight \( b = (0, 0) \) and so, requiring the \( N \)-property, this must be flat space. Therefore, we can write
\[ 2\ell^2 n^2 = 2 du^2 dv^2 = -dT^2 + dX^2. \]

Based on the previous discussion, we can find two classes of pseudo-Riemannian Kundt VSI metrics. They can be written as
\[ ds^2 = 2 du^1 (dv^1 + H du^1 + W_{\mu_1} dx^{\mu_1}) + 2 du^2 dv^2, \] (28)
where:

null case:
\[ W_{\mu_1} dx^{\mu_1} = u^1 W^{(1)}_x(u^1, u^2, v^1) du^2 + W_0(u^1, u^2, v^2) du^2, \]
\[ H = u^1 H^{(1)}(u^1, u^2, v^2), \] (29)

spacelike/timelike case:
\[ W_{\mu_1} dx^{\mu_1} = u^1 W^{(1)}(u^1, x) dX + W_0(u^1, T, X) dT + W_0(u^1, T, X) dX, \]
\[ H = \frac{(u^1)^2}{8} W^{(1)}_x(u^1, T, X) + H^{(0)}(u^1, T, X), \] (30)
and
\[ W^{(1)} = -\frac{2\epsilon}{X}, \quad \text{where} \quad \epsilon = 0, 1. \] (31)

We note that these possess an invariant null line if \( W^{(1)} = 0 \), and a two-dimensional invariant null plane if \( W_0 = 0 \) for the null case\(^6\).

4.2. The (2, 3)-signature case

Considering the 5D (2+3)-signature case, we can write
\[ ds^2 = 2(\ell^1 n^1 + \ell^2 n^2) + (m^1)^2. \] (32)

Again considering the pseudo-Riemannian Kundt case, we see that the first level pseudo-Riemannian Kundt has three-dimensional transverse space. At the second level, the transverse space is one dimensional. We can thus choose \( \omega^I = (dx)^2 \). At the second level, we therefore get the standard Lorentzian Kundt VSI spaces
\[ ds^2_I = 2 du^2 (dv^2 + H^2 du^2 + W^2 dx) + (dx)^2 \] (33)

where
\[ H^2 = \frac{(u^1)^2}{8} (W^{2,1})_x^2 + u^1 H^{2,1}(u^1, u^2), \] (34)

\(^6\) In order for the spacelike/timelike case to possess an invariant null 2-plane, it needs to be a special case of the null case.
us several cases. The metric can be written as

\[ W_{\mu_2}^2 \, dx^{\mu_2} = v^2 W_{\mu_1}^{2,1}(dx) + W_{\mu_1}^{2,0}(u^1, u^2, x) \, dx, \]

where

\[ W_{\mu_1}^{2,1} = \frac{-2\epsilon}{x}. \]  

Then using these metrics and solving the remaining equations for the 5D Kundt metric give us several cases. The metric can be written as

\[ ds^2 = 2 \, du^1 (dv^1 + H^1 \, da^1 + W_{\mu_2}^1 \, dx^{\mu_2}) + 2 \, du^2 (dv^2 + H^2 \, da^2 + W^2 \, dx) + (dx)^2, \]

where the functions \( H^2 \) and \( W^2 \) are given by equations (34) and (35), respectively.

**Case 1.** \( \epsilon = 1 \):

\[ H^1 = (v_1)^2 H_{u^1}^{1,(2)} + (v_1) H_{u^1}^{1,(1)}(u^1, u^2, v^2, x) + H_{u^1}^{1,(0)}(u^1, u^2, v^2, x), \]

\[ W_{\mu_2}^1 \, dx^{\mu_2} = v^1 W_{\mu_1}^{1,1} + W_{\mu_1}^{1,0}(u^1, u^2, v^2, x) \, dx^{\mu_1}, \]

where, using the definition \( (u^1, v^1, u^2, v^2) = (u, v, U, V) \),

\[ W_{u^1}^{1,1} = -\frac{2dV}{V + Cx + Dx^2} + \frac{[2[V + Cx + Dx^2]x + 2[Dx + x(CD - C_0) + x^2(D^2 - D_0)] dU}{V + Cx + Dx^2}, \]

\[ H_{u^1}^{1,(1)} = -\frac{x[2(CD - C_0) + x(D^2 - 2D_0)]}{2[V + Cx + Dx^2]^2}, \]

where \( C = C(u, U) \) and \( D = D(u, U) \) are arbitrary functions. We note that

\[ W_{u^1}^{1,1} = d\phi - \phi_{,u} \, du, \quad \phi = 2 \ln x - 2 \ln[V + Cx + Dx^2] + 2 \int D(u, U) \, dU. \]

**Case 2.** \( \epsilon = 0 \), *null*:

\[ W_{\mu_2}^1 \, dx^{\mu_2} = v^1 W_{u^1}^{1,1}(u^1, u^2, x) \, da^2 + W_{\mu_1}^{1,0}(u^1, u^2, v^2, x) \, dx^{\mu_1}, \]

\[ H^1 = v^1 H_{u^1}^{1,(1)}(u^1, u^2, v^2, x) + H_{u^1}^{1,(0)}(u^1, u^2, v^2, x). \]

We note that these possess an invariant null line if \( \epsilon = 0 \) (null case), and \( W_{u^1}^{1,1} = 0 \). The metric possesses a two-dimensional invariant null plane if \( \epsilon = 0 \), \( W_{u^1}^{1,0} = W_{u^2}^{1,0} = 0 \) and \( \partial_{x^k} W_{u^1}^{1,0} = 0 \).

**4.3. A class of \((k, k + m)\)-signature VSI metrics**

We can now give a class of metrics that are VSI and are the generalizations of the null case mentioned previously. We write them as

\[ dx^2 = \sum_{k=1}^{k} 2\ell^l \, n^l + \sum_{i,j=1}^{m} \delta_{ij} \, m^i m^j, \]

where

\[ \ell^l = du^l, \]

\[ n^l = du^l + [v^l H_{u^1}^{1,(1)}(u^1, v^0, x^1) + H_{u^1}^{1,(0)}(u^1, v^0, x^1) \, da^1 + [v^l W_{u^1}^{1,1}(u^1, v^0, x^1) \, da^{l+1} + W_{\mu_1}^{1,0}(u^1, v^0, x^1) \, dx^{\mu_1}], \]
\[ m^i = dx^i, \]  
(45)

and where the indices have the following ranges:

\[ a = 1, 2, \ldots, k; \quad a_I = I + 1, \ldots, k; \quad i = 1, \ldots, m, \]
(46)

In the Appendix a sketch of a proof is given which shows that these spaces are indeed VSI.

5. A class of Ricci-flat metrics

Let us consider the special case where the only non-zero functions are \( H_I, (0) \):

\[ t^l = du^l, \quad n^l = dv^l + H_I, (0) (u^p, v^B, x^i) du^l, \quad m^l = dx^l. \]
(47)

We note that these are all Walker metrics possessing an invariant \( k \)-dimensional null plane. The only non-zero components of the Ricci tensor are

\[ R_{u^l u^l} = -\Box H_I, (0), \]

where

\[ \Box = \sum_{J=1}^{k} 2 \left( \frac{\partial}{\partial u^J} - H_I, (0) \frac{\partial}{\partial v^J} \right) \frac{\partial}{\partial v^J} + \sum_i \left( \frac{\partial}{\partial x^i} \right)^2. \]

We note that in general the Ricci operator, \( R = (R_{\mu \nu}) \), is 2-step nilpotent; i.e. \( R^2 = 0 \). In order for this metric to be Ricci-flat, we need to solve the \( k \) equations

\[ \Box H_I, (0) = 0. \]
(48)

Since the functions \( H_I, (0) \) do not depend on \( v_J \), for \( J = 1, \ldots, I \), these equations simplify and we have

\[ \Box H_I, (0) = \left[ \sum_{J=I+1}^{k} 2 \left( \frac{\partial}{\partial u^J} - H_I, (0) \frac{\partial}{\partial v^J} \right) \frac{\partial}{\partial v^J} + \sum_i \left( \frac{\partial}{\partial x^i} \right)^2 \right] H_I, (0) = 0. \]
(49)

We can therefore start solving the equation for \( I = k \), which reduces to solving the Laplacian over the space \( \delta_{ij} dx^i dx^j \). The function \( H_I, (0) \) can then be used in the equation for \( H_{I-1}, (0) \), which again can (at least in principle) be solved. Then this can again be inserted into the equation for \( H_{I-2}, (0) \), etc. One can therefore systematically solve these equations since the equation for \( H_I, (0) \) only involves the functions \( H^{I+1}, (0), H^{I+2}, (0), \) etc.

5.1. Neutral 4D space

Consider first the neutral 4D case. Here we have, \( H^2 = 0 \); consequently, there is only one differential equation that needs to be solved:

\[ \Box H^{I,(0)} (u^1, u^2, v^2) = \frac{\partial^2}{\partial u^2 \partial v^2} H^{I,(0)} (u^1, u^2, v^2) = 0. \]
(50)

This can be solved in the standard way

\[ H^{I,(0)} (u^1, u^2, v^2) = f(u^1, u^2) + g(u^1, v^2), \]
(51)

for arbitrary functions \( f \) and \( g \). Consequently, we get the standard Ricci-flat neutral metrics

\[ ds^2 = 2 du^1 \left[ dv^1 + (f(u^1, u^2) + g(u^1, v^2)) du^1 \right] + 2 du^2 dv^2. \]
(52)

This is also, by construction, a VSI space.
5.2. The (2, 3)-signature case

Here, requiring Ricci flatness, we get the two equations

\[ \Box H^{1,0}(u^1, u^2, v^2, x) = \left( \frac{\partial^2}{\partial u^2 \partial v^2} + \frac{\partial^2}{\partial x^2} \right) H^{1,0}(u^1, u^2, v^2, x) = 0, \]
\[ \Box H^{2,0}(u^1, u^2, x) = \frac{\partial^2}{\partial x^2} H^{2,0}(u^1, u^2, x) = 0, \]
\[ (53) \]

These two equations, which are the Laplacians in flat one- and three-dimensional space, respectively, can easily be solved.

6. Discussion

In this paper we have considered the class of VSI spaces in arbitrary signature spaces. By using a boost weight classification of tensors we were able to give a set of necessary criteria for a space to be VSI. Then we constructed a set of spaces that had this property and, consequently, are VSI spaces. These spaces were all of the form of a pseudo-Riemannian Kundt spacetime which is a generalization of the Lorentzian Kundt metrics. We also discussed the related Walker metrics.

However, there are still a few open questions.

1. Do all VSI metrics possess the \( N^{G} \)-property? A stronger question is:
2. Do all VSI metrics possess the \( N \)-property?
3. Are all VSI metrics of pseudo-Riemannian Kundt form?

In the Lorentzian case, the answer to these questions is ‘yes’ (questions 1 and 2 are equivalent in the Lorentzian case), but for other signatures there is the possibility for other types of VSI metrics.

This paper therefore sets the stage for further investigations on VSI metrics of spaces of arbitrary signature.

Appendix. Sketch of the VSI proof

Here we give a sketch of a proof that the metrics in section 4.3 are indeed VSI. Therefore, consider the metric given by equation (42). The frame is given by

\[ \ell^I = du^I, \]
\[ (A.1) \]

\[ n^I = du^I + \left[ v^I H^{1,1}(u^a, v^a, x^i) + H^{1,0}(u^a, v^a, x^i) \right] du^I \]
\[ + \left[ v^I W^{1,1}(u^a, v^{a+i}, x^i) du^{I+1} + W^{1,0}(u^a, v^{a+i}, x^i) dx^{I+i} \right], \]
\[ (A.2) \]

\[ m^I = dx^I. \]
\[ (A.3) \]
We will investigate the Ricci rotation coefficients, $\Gamma^\mu_{\alpha\beta}$. By the Cartan structural equations, these can be deduced by the coefficients of the exterior derivative of the null frame:

$$d\omega^\mu = -\Gamma^\mu_{\alpha\beta}\omega^\alpha \wedge \omega^\beta.$$ 

Let us use the above null frame and check the boost weight of the connection coefficient $\Gamma^\mu_{\alpha\beta}$. Recall that an index $\ell^I$ downstairs (or $n^I$ upstairs) has an associated $-1$ boost weight, while an index $n^I$ downstairs (or $\ell^I$ upstairs) has an associated +1 boost weight. We will, in short, refer to the boost weight as a triple $(\ast, \ast, \ast)$ which corresponds to the indices $(\alpha < I, a = I, a > I)$.

We note that $d\ell^I = 0$ and $dn^I = 0$. All the linearly independent connection coefficients are therefore obtained from $dn^I$:

$$dn^I = H^{I,(1)}(u^a, v^{a_I}, x^I) \, du^I \wedge \ell^I + [v^I \, dH^{I,(1)}(u^a, v^{a_I}, x^I) + dH^{I,(0)}(u^a, v^{a_I}, x^I)] \wedge \ell^I$$

$$+ W^{I,(1)}(u^a, v^{a_{I+1}}, x^I) \, du^I \wedge \ell^{I+1} + \left[ v^I \, d\left[ W^{I,(1)}(u^a, v^{a_{I+1}}, x^I) \right] \wedge \ell^{I+1} + d\left[ W^{I,(0)}(u^a, v^{a_I}, x^I) \, dx^{a_I} \right] \right].$$

We see that all the coefficients fulfill the $N$-property; consequently, the connection coefficients $\Gamma^\mu_{\alpha\beta}$ satisfy the $N$-property.

We can see from the previous equations that the Riemann tensor, $R$, also fulfills the $N$-property. The covariant derivative of a tensor $T$ can, symbolically, be written as

$$\nabla T = \partial T - \sum \Gamma \ast T.$$

The second term on the right-hand side is algebraic, so if $T$ and $\Gamma$ both fulfill the $N$-property, so will the term $\sum \Gamma \ast T$. Therefore, we only have to check the partial derivatives, $\partial T$.

For the Riemann tensor, we can now use the Bianchi identity and the generalized Ricci identity to show that all covariant derivatives of the Riemann tensor also fulfill the $N$-property. Alternatively, since the dangerous terms that can potentially make the derivatives violate the $N$-property are the partial derivatives with respect to $v^I$, we can carefully keep track of the $v^I$ dependence of each of the components. We then note that boost weight terms $(0, -1, \ast)$ will either be independent of $v^I$, or linear in $v^I$. However, the terms that are linear in $v^I$ are of boost weight $(0, -1, -1)$ and independent of $v^{I+1}$. Therefore, $\partial T$ will still obey the $N$-property.
